THE *ILLUSTRATED* GLOBE ENCYCLOPÆDIA.

F the sixth letter of the English alphabet, occupying the same position in the Phœnician alphabet as *vau*, from which it has been derived through the Latin; in Greek its place was originally occupied, both in form and sound, by the archaic digamma. Its proper phonetic value, which is that of a softened *v*, must be carefully distinguished from the sound of *ph*, the Greek φ, which is really an aspirated *p*. In transliteration from Oriental languages this confusion often arises. But though these two letters are etymologically distinct, few languages retain both, and either can be forced to serve the purpose. The Greek *ph* is often represented in primitive Latin words by F, as *phu*- = *fui*, the same root as of Eng. 'be;' but in words directly borrowed, as *Philip*, it was retained, to be entirely discarded by modern Italian. The German pronunciation of *v* is hardly distinguished from our F. The interchanges of F are most numerous with the cognate labials and aspirates—Eng. 'father' is Ger. *vater* and Lat. *pater*; Lat. *fora* is Gr. *thura* and Eng. 'door;' Lat. *fero* is Eng. 'bear;' Eng. 'five' is Ger. *fünf*, Lat. *quinque*, and Gr. *pente*. As an abbreviation, FF. stands for *fragmenta*, used in referring to the Digest of Justinian. F. commonly stands for fellow, as F.R.S., Fellow of the Royal Society. F was also the letter formerly branded on felons in England who claimed the benefit of clergy.

F, in music, a note a perfect fourth above C. The vibration ratio F : C is equal to 4 : 3.

Faam', or **Fah'am** (*Angræcum fragrans*), a species of *Orchidaceæ* (q. v.) or orchids, found plentifully in the Mascarene Islands and the E. Indies. This plant is noted for the odour of its leaves, due to the presence of Coumarin (q. v.). The leaves are used in France for making an infusion popularly known as 'Isle of Bourbon tea,' greatly in vogue as a stomachic, and said to be also beneficial in consumption.

Faba'ceæ. See LEGUMINOSÆ.

Fa'ber, John, the name of two engravers in mezzotinto, of some repute in the 18th c., though of but little account now. The elder, who was born in Holland, and died at Bristol in 1721, besides engraving, drew portraits with the pen on vellum. His son, who died in London in 1756, was a superior artist. His best portraits are those of the beauties of Hampton Court, of the Kit-Cat Club, and of the Perceval family in the history of the House of Yvry.

Faber, Rev. George Stanley, an Anglican divine, was the eldest son of Rev. Thomas F., the descendant of a French Protestant refugee, and born 25th October 1773. After a successful career at Oxford, where he became fellow and tutor of Lincoln College, he was made Bampton Lecturer in 1801, and his discourses were published the same year under the title of *Horæ Mosaicæ* (2d ed. 1818). He married, and held various appointments, settling down finally in 1832 as master of Sherburn Hospital, near Durham, where he died, January 27, 1854. F. was a voluminous and popular writer on prophecy; among his works are *Dissertation on the Mysteries of the Cabiri* (1803); *The Origin of Pagan Idolatry* (1816); *Papal Infallibility* (1851); *The Revival of the French Emperorship Anticipated from the Necessity of Prophecy* (1853).—His nephew, **Francis William F.**, born June 28, 1815, is notable for having, while an Anglican clergyman and Rector of Elton, been converted to the Roman Catholic faith (1845), and joining Dr Newman's Oratory of St Philip Neri. F., who was an eloquent preacher and voluminous writer both of prose and of poetry, became superior of the Oratory at Brompton, and died September 26, 1863. Among his works, several of which have been translated into French, German, Dutch, &c., may be mentioned *Sir Lancelot, a Poem* (2d ed. 1858), *The Spirit and Genius of St Philip Neri* (1850), and *Spiritual Conferences* (1859). See Bowden's *Life of F. W. F.* (1869).

Fa'bius, the name of an old Roman patrician family, whose members were distinguished in war, literature, and the arts. From B.C. 485–479 a F. constantly appears in the list of consuls; but according to the family legend, which passes for history, having been alienated from their fellow-patricians, the clan retired to the river Cremera, where (B.C. 477) they were destroyed by the Veientes, one youth, left at Rome, alone having escaped.—**Quintus F. Rullianus**, or **Rullus**, who first of the Fabian gens bore the surname Maximus, was the most distinguished Roman general in the second Samnite war. His march through the Ciminian forest, though a rash and hazardous step, was followed by a decisive victory over the Etruscans at the Vadimonian lake, B.C. 310, and two years later he dispersed the Umbrians on the Upper Tiber.—**Quintus F. Maximus Verrucosus**, 'whose wise delay restored the Roman state,' was named *Cunctator*, or the 'Lingerer,' from the persistence with which, in the second Punic war, he avoided all direct encounter with Hannibal. Appointed dictator after the disaster at Lake Trasymene, his policy nearly achieved success when, following the invader on his retreat from Campania to Apulia, he closed the passes of the Apennines against him. Hannibal only escaped by a dexterous stratagem. The popular party at Rome misinterpreted the Fabian policy, and demanding more aggressive tactics, associated Minucius in command with the dictator; but the change of policy issued in the disgraceful rout at Cannæ. In his fifth consulship (B.C. 209) F. recaptured Tarentum. He died B.C. 203. Mommsen pictures him as a man 'zealous in his reverence

for the good old times, for the political omnipotence of the senate, and for the command of the burgomasters—one who looked, next to sacrifices and prayer, to a methodical prosecution of the war as the main means of saving the state.'—**C. F. Pictor**, whose distinction as a painter acquired the name Pictor for a family of the Fabii. He lived about 300 B.C.—**Q. F. Pictor**, grandson of the preceding, flourished about 220 B.C. He was the earliest of the Roman annalists, and his work was of great value.

Fa'ble (Fr. *fable*, Lat. *fabula*, 'a narrative or story,' from *fari*, 'to speak'), a fictitious tale in prose or verse, in which animals or inanimate things are made to speak and act without regard to possibility, and which is intended to illustrate a moral truth or practical axiom, sometimes added to the story in the shape of a brief maxim called the *moral*. 'Jotham's F. of the trees (Judges ix.) is the oldest extant,' says Addison, 'and as beautiful as any made since.' Fables are especially popular in the East, and among the earliest known collections of them are Bidpai's (q. v.) or Pilpai's Indian and Lokman's Arabic fables. Some maintain the East to be the birthplace of F., and Max Müller traces La Fontaine's F. of the Milkmaid to a Sanskrit source. Among the most famous fabulists are the Greeks Æsop (q. v.) and Babrius (q. v.), the Latin Phædrus (q. v.) who recast the fables ascribed to Æsop, and added others of pure Roman origin, Aphthonius, a Greek prose writer, and Avianus, a Latin versifier of the 4th c., Planudes (q. v.), a Greek of the 14th c., Boner, and in modern times, La Fontaine (q. v.), who gave a novel piquancy to F. writing, Gay (q. v.), and the Spaniard Yriarte, who united the spirit of the Æsopian fables with the style of the Spanish romances. Fables were very popular in Germany in the 18th c., the best-known writers of them being Gellert (q. v.), Hagedorn (q. v.), Lichtwer, and Pfeffel. The greatest recent fabulist is the Russian Kriloff (q. v.), and many exquisite fables occur in Andersen's works. The most ambitious specimen of F. writing in England since Gay's time is the *Fables in Verse* of Lord Lytton ('Owen Meredith').

Fab'liau, pl. **Fabliaux** (formerly *fableau*, originally *fablel*, from Lat. *fabulellus*, a dim. of *fabula*, 'a story'), short metrical tales written by the early French poets, which, unlike the *sirventes* or songs of praise, the *tensons* or fantastic disquisitions on the 'art of love,' and the *lais* or miniature romances, were facetious and satirical, and mostly founded on proverbs and comic incidents. They are said to have originated at festive meetings, for which their brevity and piquancy were well adapted. While the *chansons de geste* deal with chivalrous adventure, the F. picture the humble and *bourgeois* life of the middle ages, and assail the vices and wrongs of the time, sparing neither king, baron, nor saint. Although stained with indecency, they evince fancy, pathos, and humour, bold satire, and greater narrative skill than the long rhyming romances. They belong principally to the 13th c., and are written generally in octosyllabic verse and in dialogue. Their sly banter and arch gaiety make them pleasanter reading than the prolix epics of the *trouvères*, or the lyrics embodying the amorous ritualism of the *troubadours;* and they were the delight and instruction of the people, until the the Church, dreading their anti-clerical influence, made them a medium for orthodox doctrine. This brought them into popular disrepute; they died away during the 15th c., and their place was taken by the *sotties* or farces. From the F. arose the French comedy. In *Maistre Pierre Pathelin*, the first French comedy, we see the very spirit of the F., the same love for ludicrous incident and merry cajolery. Molière's *Médecin Malgré Lui* and *Georges Dandin*, and Piron's comedy of *Le Fils Ingrat* were founded on old F. The subjects of the F. were drawn from very varied sources—from the Old and New Testament, the *Acta Sanctorum*, the *Gesta Romanorum*, Apuleius, Ovid, and especially from the East. Many were adapted from the *Romance of the Seven Sages*. But notwithstanding their frequent Eastern colouring, their character is distinctly French; their authors are the earliest representatives of that peculiar *esprit Gaulois* which sparkles in Villon, Marot, Voltaire, and La Fontaine, preserving the same character in Rutebeuf and in Béranger. This peculiarly French quality, which we first find in the F., consists of a laughing, poignant irony, a frolic piquancy, expressed with Attic lightness and clearness, distinct alike from the boisterous humour of Rabelais and the prim, chill graces of the classical school. The *fablieri* have supplied innumerable themes to succeeding writers. From them La Fontaine drew many of his raciest stories, and Boccaccio most of the plots for his *Decamerone*. Chaucer was indebted to them for his tales of the Reeve, Frankeleyn, and Schypman. Stories now known through Europe were first popularised by the F.; for example, the tale of Griselda was retold by Chaucer and Hans Sachs from Boccaccio, who took it from a *fableor*. After the Conquest Norman minstrels brought F. into England, where they were imitated in such poems as the *Owl and the Nightingale*, and the story of *Sir Cleges*. The *fablieri* were not mere sprightly, licentious humourists. They were bold satirists, whose writings were a check on the priests and nobles, and who anticipated Cervantes in ridiculing chivalry. Among the most noted of them were Bernier, Gautier de Coinsi, Henri d'Andeli, Hugues Piancelle, Jean de Boves, Jean le Chapelain, and, especially, Rutebeuf, a wandering minstrel of the 13th c., the representative *fablier*, author of *Charlot le Juif*, *Moine Sacristain*, &c. The *Vert-Vert* of Gresset is a perfect modern specimen of a F. See Demogeot's *Littérature Française* (Par. 1870), Besant's *French Humourists* (Lond. 1873), and Le Grand's *Fabliaux*, *Histoire de la Littérature Française*, by Charles Gidel (Par. 1875).

Fabrett'i, Raffaell'e, a famous Italian archæologist, born in 1618 at Urbino, repaired at an early age to Rome, and devoted himself to the study of its antiquities. His employments as papal treasurer, chancellor to the papal embassy at Madrid, and keeper of the papal archives in the castle of St Angelo gave him the best facilities for studying the classic works of the ancients. He is best known by his *De Aquæductibus Veteris Romæ* (Rome, 1680), his *De Columna Trajani* (Rome, 1683), and his *Inscriptionum Antiquarum, quæ in Ædibus Paternis asservantur, Explicatio* (Rome, 1699; 2d ed. 1702). He died in Rome, 7th January 1700. His valuable collections are preserved in the palace of Urbino.

Fabria'no, a city in the province of Macerata, Italy, 23 miles N.W. of the city of Macerata, has a cathedral and several churches containing numerous specimens of Italian sacred art. It has also been an important seat of paper manufacture for upwards of three centuries. Pop. 7500.

Fabriano, Gentile Da, an Italian painter, born at Fabriano about 1370, repaired at an early age to Florence to study under Fiesole. Among his first works were the fresco of the Madonna, preserved in the cathedral of Orvieto, which earned him the title of *magister magistrorum*, and an 'Adoration of the Kings,' now in the gallery of the Academy of Florence, a work dated 1423, and one of the finest works of the school of Giotto. He afterwards painted sacred subjects for the churches of Sienna, Perugia, Gubbio, Fabriano, &c., and eventually removed to Venice, where the senate gave him the pension of one ducat *per diem* and the privilege of wearing the toga of the patricians, in recognition of the merit of his great fresco—a sea-fight between the Venetian fleet and that of the Emperor Barbarossa—painted for the council hall of the Doge's palace. The work was destroyed by fire in 1574. F. was employed by Pope Martin V. to decorate the church of San Giovanni Laterano, in which he painted the history of St John, figures of several of the prophets, &c. He died in 1450. His works are bright and cheerful. Michael Angelo said of him, 'His genius is like his name—*gentile*.'

Fabri'cius or **Fabriz'io, ab Acquapenden'te, Geron'imo**, a famous Italian anatomist, was born at Acquapendente, near Orvietro, in 1537. He studied under Fallopius at Padua, where he was made professor of anatomy in 1565. F. soon became celebrated as a teacher, and his class-room was thronged by students from the various countries of Europe. After lecturing for fifty years he retired with a large fortune, and died at his country-seat on the Brenta, May 21, 1619. It was suspected that his heirs had poisoned him. Harvey, who attended F.'s lectures, states that his discovery of the circulation of the blood was suggested by F.'s remarks on the valves of the veins. F. wrote several Latin treatises on anatomy and surgery, showing careful, accurate investigation, and clear and vigorous in style. His complete works were published, with a memoir by Albinus, at Leyden in 1723, under the title *Opera Omnia Anatomica et Physiologica*. See Thuilius' *Memoria Hier. Fabricii* (Padua, 1619), and Salvadori's *Notitiæ Historico-Scientificæ de Fabricio* (Padua, 1837).

Fabricius, Johann Christian, a Danish entomologist, born at Tondern, Slesvig, 7th January 1743; studied medicine at Copenhagen, Edinburgh, and at Upsala under Linnæus; was

chosen professor of natural history at Kiel in 1775; devoted himself to entomology; travelled over much of Europe, visiting Russia and England; and died at Kiel, 3d March 1808. His system of classification is by no means natural, yet entomology received from him a fresh impulse; and though later and better *savans* have pushed him into the background, he has a claim to be considered almost the founder of the science. His most important works are *Systema Entomologiæ* (Copen. 1775; revised and enlarged, 1792-94); *Supplementum Entomologiæ* (1797); and *Philosophica Entomologia* (Copen. 1778).

Fabricius Lusci'nus, Cajus, figures in Roman history as a model of antique simplicity, courage, and patriotism. When consul in B.C. 282, he delivered the city of Thurii, which was besieged by the Lucanians and Bruttii, and subsequently defeated the Samnites. When Pyrrhus came over from Greece to assist the Tarentines, F. was sent to confer with him, after the defeat at Heraclea (280), about a ransom of captives. The Greek monarch offered him gold if he would try to induce the senate to make peace, but F. was proof against both his bribes and his threats. Pyrrhus was so much impressed with his patriotic fidelity that he restored the prisoners without ransom. During F.'s second consulship, in 278, the physician of Pyrrhus secretly paid him a visit, and treacherously offered to poison his master for a reward. F. indignantly handed him over to the king, who again expressed his thanks by setting free all his Roman prisoners. While Pyrrhus was absent in Sicily, F. was victorious over the peoples of Lower Italy. He died poor, about 250, but the state charged itself with the upbringing of his only child.

Fabro'ni, An'gelo, an Italian biographer, born at Marradi in Tuscany, 25th September 1732, completed his studies at Rome. He wrote first in Latin, and afterwards in Italian; commenced at Pisa in 1771 his *Giornale de Letterati*, which at its close in 1796 formed 102 vols., and died at Pisa, 22d September 1803. Among his works are *Vitæ Italorum Doctrina Excellentium qui Sæculis XVII. et XVIII. floruerunt* (Pisa, 1778-1805, 20 vols.); *Laurentii Medicei Magnifici, Vita* (Pisa, 1784); *Magni Cosmi Medicei, Vita* (Pisa, 1789); *Elogi d' Illustri Italiani* (2 vols. Pisa, 1786-89).

Fa'byan, Robert, an English chronicler, born of a good Essex family in London, in the second half of the 15th c. He was a member of the Drapers' Company, and took an active part in civic affairs, becoming sheriff and alderman, and afterwards assessor of the London wards to Henry VII. He died February 28, 1512. He wrote a *Concordance of Histories* (first printed in 1516), compiled from monkish annalists, and marked by a strong ecclesiastical bias. It gives the history of Britain from Brut to 1504, in English prose, and has a prologue and seven episodes in verse.

Façade' (Fr.; from the Ital. *facciata*, Lat. *facies*), a term in architecture which at first signified the principal front of a building, but is now applied to any front or face of an edifice. It is chiefly used in speaking of important buildings.

Facciola'ti, Gia'como, an Italian scholar, was born at Torreglia, near Padua, January 4, 1682. He studied at the ecclesiastical seminary of Padua, of which he finally became the head. F. distinguished himself in criticism, grammar, antiquities, metaphysics, and theology, and wrote Ciceronian prose, but is remembered chiefly as a Latin lexicographer. He revised the lexicon of Schrevelius, and along with his pupil Forcellini produced a new edition of the *Calepine Lexicon*, or *Lexicon Septem Linguarum*. Finally, the same literary partners set to work to produce a new Latin dictionary, the basis of all subsequent dictionaries of the kind. F. did not live to see it completed (1771), as he died August 26, 1769.

Face. The F. is composed of fourteen bones, of which twelve are in pairs, viz., the superior maxillary, molar, nasal, lachrymal, inferior turbinated and palate bones; and two single, namely, the vomer and inferior maxilla. It contains the cavities of the orbits, of the nose, and of the mouth. These bones are covered by the muscles of expression and of mastication; and by the contour of the bones, the degree of development of these muscles, and the amount of fat beneath the skin, the countenance in life is formed. The forehead, eyelids, nose, mouth, lips, and cheeks have sets of muscles by the movements of which the various emotions may be expressed. (On the action of the facial muscles, as expressive of the emotions, see Sir Charles Bell's *Anatomy and Philosophy of Expression*.) By absorption of fat and atrophy of muscle the F. becomes much altered in disease, and the near approach of death is characterised by a peculiar expression of countenance—the *facies Hippocratica*, thus described by the ancient physician Hippocrates: 'nose pinched, eyes sunk, temples hollow, ears cold and retracted, the skin of the forehead tense and dry, the complexion livid, the lips pendant, relaxed, and cold.' The arteries of the F. come from the external carotid; its veins end in the jugular; its nerves originate in the brain.

Face-Ache. See TIC-DOULOUREUX.

Fa'cet (Fr. *facette*, 'a little face'), the name applied to the small faces of a crystal or cut gem. Steel jewellery and other metal ornaments are often *facetted*.

Fa'cial Angle. This is an angle formed by two lines, one of them descending from the most prominent part of the forehead to the incisor margin of the upper jaw, the other passing through the external auditory opening and the nasal spine. It was intended by Camper, the distinguished ethnologist, to indicate by the size of this angle the degree of projection of the face in different races of men, and the relative development of the face to the cranium. The following are several facial angles which have been measured:—(1) Faces in antique works of art, 90° or even more; (2) average European, 80°; (3) European below the average, 70°; (4) Negro, 70°; (5) young anthropoid apes, 56° to 60°; (6) old anthropoid apes, 30° to 47°. See SKULL.

Facil'ity, a term of Scotch law denoting the mental condition of a person unable in an ordinary degree to protect himself from imposition. On sufficient evidence of F. being given against any one by his heir or next-of-kin, the Court of Session will 'interdict' him. (See INTERDICTION.) Any one conscious of the infirmity may place himself under interdiction. There is no corresponding term in English law, nor any similar remedy. See IDIOTS and LUNATICS.

Fac'tor, in mathematics, is one of the numbers or symbols which go to make up a given product. Thus in the expression $3ab^2(a^4-b^4)$ the factors are 3, a, b^2, and a^4-b^4; but of these the last two can be broken up into other factors, b, b, $a-b$, $a+b$, and a^2+b^2. This process of breaking up an algebraic expression into its *elementary factors* is of great importance in analysis. The term *factorial* is given to those continued products of consecutive numbers, beginning with unity, which constantly occur in series and expansions. Thus 1.2.3.4.5 is called *factorial* five, and is usually written $\underline{|5}$.

Factor (Lat. 'doer'), in a general sense, is any one who does business for another. In English law, a F. is the agent of a merchant or trader constituted by letter of attorney. (See ATTORNEY, LETTER OF.) A F. is generally paid by commission. If he buy goods on account of his principal when he is accustomed to do so, the contract binds the principal. But if the goods have been bought or exchanged without order, the merchant may refuse to take them from the F. Formerly, the law was extremely hard on third parties in their transactions with factors. If an advance of money was made to one on the security of merchandise belonging to his principal, the principal was legally entitled to withdraw the security; and in the event of merchandise being bought from a F. not authorised to sell, the purchaser was liable, after paying the F., to have to pay the full value to the owner. To remove these hardships the Acts 4 and 6 Geo. IV. caps. 83-94 were passed, establishing the validity of contracts respecting merchandise intrusted to factors. Under 6 Geo. IV. the person in whose name goods are shipped is declared to be the owner unless the contrary can be proved.

In Scotland, the term F., besides its general legal meaning, which corresponds with the English, is especially applied to the manager for the proprietor of real (heritable) estates, for which the English equivalent is 'land-agent.' The great landowners have generally a F. resident on their estates, whose chief business it is to let the farms and draw the rents. The F. binds his principal to any engagement which he contracts within his powers. It has lately become to some extent customary to use the word *chamberlain* in Scotland as synonymous with F. in the above sense. Factors are also under certain circumstances

appointed on estates in Scotland by the Court of Session. One so appointed is called a *Judicial F.* (q. v.).

Fac'tories and Mills, Law Regarding. Various Acts have been passed for the appointment of inspectors for the preservation of the health, and for regulating the education and hours of work, of children employed in M. and F. By 3 and 4 Will. IV. c. 103, children are required to attend a school chosen by parents or inspectors, to pay the expense of which one penny in each shilling is to be deducted from the child's earnings. It is rendered unlawful to employ children unless they produce weekly to the factory master the schoolmaster's ticket of attendance. Interior walls of mills and ceilings of rooms must be limewashed yearly.

Act 7 and 8 Vict. c. 15 empowers inspectors to enter factories by day and night, to examine the inmates, the register, and other documents kept in pursuance of the Act. Penalties are imposed on persons endeavouring to prevent the examination of any child by the inspector, or otherwise endeavouring to impede him in the execution of his duty. Inspectors are empowered within limits to fix the surgeon's fees and appoint the times of his visits. The Act makes stringent regulations for preventing injury to the health of the children and 'young persons'—those between thirteen and eighteen years old—and for prevention of accidents from the machinery. By 16 and 17 Vict. c. 104, no 'child'—that is, one under thirteen years old—shall be employed in any factory before six o'clock in the morning nor after six o'clock in the evening of any day, nor after two o'clock on Saturday. But between 30th September and 1st April children may be employed for one month on any day but Saturday from 7 A.M. to 7 P.M. There are various other Acts extending the operation of the Factory Acts, and making further regulations as to hours of employment and other matters concerning the health of the employed. Any manufactory in which fifty or more persons are employed is under the Acts a factory. See WORKSHOP REGULATION ACT.

Fac'ulty (Lat. *facultas*, a 'power,' 'means,' or 'opportunity'), in English law, is a privilege granted to do something generally prohibited by law. There is a court for the purpose under the Archbishop of Canterbury called the *Court of Faculties and Dispensations*, which has power to grant dispensations for marriages without publication of banns (see BANNS), for a deacon under age to be ordained, and for exceptional procedure in other matters connected with the Church. The bishop of the diocese may grant a F. for erection of a monument, or for other addition or alteration in a church. See PEW.

Faculty. See UNIVERSITY.

Faculty of Advocates (Scotland). See ADVOCATE.

Faculty, Dean of (Scotland). See DEAN OF FACULTY.

Fæ'ces (Lat. 'dregs,' 'impurities'). The undigested materials of the food, mixed with products excreted from the mucous membrane of the bowels, constitute the F. Microscopical examination shows usually disintegrated muscular fibre, cartilage cells, elastic fibres, free fatty matter, crystals of cholesterine, the chlorophyll of cells from plants, portions of broken-down vegetable matter, such as starch grains, spiral vessels, &c., bile salts, bile colouring matter, epithelium cells, mucous matter, corpuscles, saline matter, especially the crystals of the ammoniaco-magnesian or triple phosphate, &c., &c. Usually F. contain about 70 per cent. of water, and an estimation of the amount of nitrogen yielded by the F. was about 42 grains per day. The ash of F. consists of alkaline chlorides and sulphates, phosphate of soda, phosphates of lime and magnesia (in large amount), phosphate of iron, sulphate of lime and silica. About 8·55 of F. are evacuated daily. See DEFÆCATION.

Faed, John, a Scottish artist, son of a millwright, was born at Burley Mill, in the stewartry of Kirkcudbright, in 1820. He early showed a strong love of painting, and in 1841 went to Edinburgh, where in 1850 he exhibited several pictures, which soon made him widely known. In 1864 he removed to London. Among his works, which are mostly of humble Scottish life, are 'The Cottar's Saturday Night', 'The Wappenschaw,' 'Tam O'Shanter,' 'Auld Mare Maggie,' 'John Anderson my Jo,' &c.

—**Thomas F., R.A.,** brother of the above, was born at Burley Mill in 1826, joined the Edinburgh School of Design, where he received instruction from Sir W. Allan, and in 1849 was made an Associate of the Royal Scottish Academy. In 1852 he settled in London, and began to exhibit annually in the Royal Academy. His popularity continued to increase; he was made an A.R.A. in 1859, an R.A. in 1864, and an honorary member of the Vienna Royal Academy in 1875. Among his works are 'Scott and his Friends at Abbotsford,' 'The Mitherless Bairn,' 'The First Break in the Family,' 'From Dawn to Sunset,' 'Baith Faither and Mither,' &c. His paintings, which are rich in tint and free in execution, are mostly faithful transcripts of the pathetic and humorous aspects of Scottish rustic life.

Faen'za (the *Faventia* of the Romans), an episcopal town on the Lamone, in the province of Ravenna, N. Italy, on the railroad from Bologna to Ancona, and 20 miles S.W. of Ravenna. It is well built, four main streets branching off from the principal square, which is adorned with arcades and a fountain. The cathedral, courthouse, and theatre, are the chief public buildings. F. manufactures articles of Majolica, known from the name of the town as 'Faience' (q. v.) Pop. 17,486.

Fæ'sulæ. See FIESOLE.

Fagg'ing, the name given to a system peculiar to the great public schools of England, by which the upper boys are authorised to exact certain services from the lower boys. The system is explicitly recognised by the masters, and the services demanded are regulated only by the traditions of each particular school; some of them are of a menial character, while others are connected with the common school games. F. no doubt arose from the two circumstances, formerly almost universal in England—that all the boys were permanent boarders, and that the staff of masters was too limited to exercise supervision out of working hours. The first of these circumstances naturally engendered a private organisation among the boys, which the force of tradition has stereotyped; while the latter induced a semi-public sanction. Among day-boys the relation of master and servant could never have been instituted, and under ushers it would not have been allowed to take deep root. The advantages asserted of the system are that the fags are rendered handy, independent, and obedient, that an equality of condition is enforced upon all, and that unlicensed bullying is indirectly suppressed. The evils are that the smaller boys are harassed by perpetual forced employment, which is often capricious and degrading, and that the character of the bigger boys is not improved by the almost despotic exercise of indiscriminate power. Mr. Freeman, in his *Growth of the English Constitution*, asserts that F. is a remnant of the old Teutonic custom of *commendation*, by which a free man became the 'man,' or obedient follower of a chief. A somewhat similar system, under the name of 'the Garring Law,' grew up in Heriot's Hospital, Edinburgh, in the middle of the last century.

Fahr'enheit, Gabriel Daniel, a German physicist, born at Danzig, May 14, 1686, spent most of his life as a glass-blower in England, and later in Holland, where he died, 16th September 1736. About 1720 he improved the thermometer by substituting mercury for spirits of wine. (See THERMOMETER.) In the *Philosophical Transactions* for 1724 there are five papers by him, on the boiling and freezing of water, on specific gravity, and on a barometer of new construction.

Faid'herbe, Louis Léon César, a French general, born at Lille, June 3, 1818, served in Algeria, and as Governor of Senegal; commanded the *Armée du Nord* in the Franco-Prussian war, and was beaten, greatly through the want of artillery, at St Quentin, January 17, 1871. He joined Gambetta's party, and was elected by the central canton of Lille to the National Assembly in 1871, but retired into private life on the success of the Thiers Government. Besides proving himself an able soldier, F. has written valuable scientific articles, a *Notice sur la Colonie du Sénégal* (1859), and *Campagne de l'Armée du Nord* (1871).

Faïence', or **Fayence,** an old French term formerly applied to all kinds of glazed earthenware, now restricted to fine kinds of pottery, with a soft, opaque paste, and glazed.

Fai-Fo, a commercial town and seaport of Anam, about 70

miles S. by E. of Hué, has an extensive trade with China, to which it exports sugar and cinnamon. Pop. 15,000.

Faill'y, Pierre-Louis-Charles-Achille de, a French general, born at Rozoy-sur-Serre, Aisne, January 21, 1810. He served in Algeria, distinguished himself in the Crimean war, and in 1867 won unenviable notoriety as the conqueror of Mentana. He held a command in the Franco-Prussian war, and was captured at Sedan. F. was severely censured for incapacity by his countrymen, and has not been reinstalled in command.

Fai'néants Rois (Fr. 'do-nothing kings'), the name given to the Merwing kings, who nominally held the Frankish throne from the battle of Testry in 687 to the accession of the Karoling dynasty in 752. During this period the regal authority was wielded by the mayors of the palace. See FRANCE, HISTORY OF.

Fain'ting, or **Syn'cope** (Gr. *sun* and *koptō*, 'I fall down'), is a state in which the circulation of the blood is suddenly arrested or much diminished in force and volume, causing a deadly pallor and loss of consciousness and power. F. is thus a state of suspended animation, varying in duration, and sometimes ending in death. F. usually takes place in the upright position, but not always, and the first symptoms are sudden pallor and falling down in a swoon. There are no spasms, as in hysteria, epilepsy, and convulsive affections; and no pulsation or respiratory movements, as in catalepsy. F. most frequently occurs to those of a highly nervous temperament. Those of very delicate constitution, or who may have suffered from exhausting diseases or disease of the heart, are liable to attacks of F. from very slight exciting causes, such as the close atmosphere of a room or a start. The symptoms of F. and collapse, or shock, are similar, but the latter are much more serious, and are usually associated with accidents or surgical operations. *Treatment:*—The patient should be laid on the back, with the head and shoulders very slightly elevated; tight articles of dress should be loosened; and a current of cold air directed to the face and neck. Cold water dashed on the face, and ammonia or aromatic vinegar applied to the nostrils are highly useful in exciting the nervous system. The first symptoms of returning consciousness are twitchings of the muscles of the face, followed by a deep-drawn sigh. Artificial respiration, induced by compressing the ribs and allowing them to expand, as in natural breathing, rouses the respiratory movements. Friction over the region of the heart is also useful, and galvanism sometimes succeeds when all other means fail.

Fai'oum. See FAYUM.

Fair, a privileged market regularly convened at a particular place on certain periods of the year. The word is probably derived from the Lat. *feriæ*, holidays, or days exempt from labour, which, after the establishment of Christianity, included days set apart for religious festivals in honour of the saints. On such occasions large numbers of people assembled round the monasteries. These gatherings became the origin of fairs, which were held on feast-days and Sundays. The German word *messe* signifies F. as well as Mass, a further indication of the relation between the Church and fairs. Numerous fairs are held at stated periods in various towns of the United Kingdom, chiefly for the sale of horses, cattle, and agricultural produce. Railways, and improved means of inland communication generally, have rendered many unnecessary, and diverted most from their original purpose to mere gatherings for merrymaking. Some had, indeed, become such great public nuisances, scenes of riot and dissipation, that their abolition was secured by the Fairs Act, enacted in May 1871. Bartholomew F., in London, established in the 12th c., ceased to exist in 1855; for two centuries it was a gross carnival. Throughout Europe and Asia, however, many fairs are still devoted to legitimate trade. Those of Leipsic and Nijni-Novgorod are the principal. At Leipsic three annual fairs are now held—commencing on New Year's day, Easter, and Michaelmas—each extending over three weeks. Enormous trade is carried on, and the imports of the *Zollverein* and foreign manufactured goods steadily increase every year. Merchants from all parts of the world attend. The German book-trade, of which Leipsic is the great emporium, holds a half-yearly F. The annual F. of Nijni-Novgorod, sometimes called Macarieva, is the largest in the world. It begins early in July, and lasts over two months. Traders from all parts of Europe, Central Asia, and even China, frequent it. The F. of 1874 was visited by over one million persons; the value of its imports amounted to 180,000,000 roubles (three times the value of the imports of 1847), and eight-ninths of that sum were actually realised by sales. Other Russian and Siberian towns have periodical fairs, and at Frankfurt-on-the-Main, Brunswick, Frankfurt-on-the-Oder, Vienna, Cassel, Breslau, Lyon, St Germain, &c., considerable trade is similarly transacted.

Fair'bairn, Sir William, LL.D., F.R.S., an eminent engineer, was born at Kelso, Roxburghshire, Scotland, February 19, 1789. After receiving an elementary education at the parish school of Mallochy in Ross-shire, he became apprenticed to the trade of engine-wright at Percymain Colliery, North Shields. In 1817 F. was able to begin business for himself in Manchester as a machine-maker, and speedily won success and reputation. He is chiefly notable for being among the first to build iron ships, for substituting iron for wood in the shafting of cotton-mills, and for developing Stephenson's theory of tubular bridges, of which he successfully erected a large number. F. wrote various interesting papers, on such subjects as the tenacity of boiler plates, in the *Transactions* of the Royal Society and of the Philosophical Society of Manchester; and among his more important works are *Iron, its History and Manufactures* (1863), *Mills and Millwork* (1864–65), and *Iron Shipbuilding*. F., who during his later years had many honours bestowed upon him, such as the dignity of LL.D. of Glasgow, Fellow of the Royal Society, and corresponding Member of the Institute of France, held the office of president of the British Association for the Advancement of Science in 1861 and 1862, and in 1869 was made a baronet. He died August 18, 1874. See Smiles's *Lives of Engineers*.

Fair'fax, Edward, son of Sir Thomas F. of Denton, Yorkshire, was born in the reign of Elizabeth. He spent a studious tranquil life at Fuyistone, near Denton, and died about 1632. His translation of Tasso's *Gerusalemme Liberata*, first published in 1600, under the title of *Godfrey of Bulloigne*, preserves the octave rhyme and much of the music and voluptuous splendour of the original; and notwithstanding occasional obscurity and undue licence of fancy, remains an English classic and one of the best translations in our language. The 7th edition, published by Charles Knight in 1853, has a brief memoir of the translator. F. also wrote eclogues, &c., now lost, and a treatise on *Demonology*. See Leigh Hunt's *Essay on F.'s Tasso*.

Fairfax, Thomas Lord, an English general, son of Ferdinand Lord F., was born at Denton, Yorkshire, in January 1611. He served under Lord Vere in Holland, and when the civil war began in 1642, was made a general of cavalry in the army of the Parliament. In 1644 he defeated the Royalists under Bellasis, and commanded the right wing in the battle of Marston Moor. He succeeded Essex as leader of the Parliamentary forces, having Cromwell as his lieutenant-general, and commanded at the victory of Naseby in 1645. Henceforth, as Cromwell rose in power, F.'s influence lessened, though he was nominally commander-in-chief until 1650, when he resigned on being ordered to set out against the Scots, who had declared for the king. He then spent several years in retirement in Yorkshire, took part with Monk against Lambert in 1659, was elected member for Yorkshire in 1660, was one of the committee for promoting the Restoration, and died at Nun Appleton, Yorkshire, November 12, 1671. F. wrote *Short Memorials of Thomas Lord F.* (1699), and several works in prose and verse.

Fair Head (Scand. *farr*, 'a sheep'), otherwise **Benmore Head** (*i.e.*, 'great hill head'), a promontory on the coast of Antrim, Ireland, 3 miles S. by E. of the island of Rathlin, and rising perpendicularly from the sea 636 feet. Geologically it belongs to the coal-measures, but columnar greenstone forms its upper portion.

Fai'ries, or **Elves.** Several derivations of the word *fairy* are suggested, among others the Celtic *faer*, 'to charm;' Old Eng. *fere*, 'a companion,' from *faran*, 'to go;' and the Persian *peri*, pronounced in Arabic *feri*. The true root is probably the Lat. *fatum*, whence through the mediæval *fatare*, 'to enchant,' the Fr. *faer*, *feer*, from which came *faerie*, signifying first illusion, then the land of illusion, fairyland, and lastly an inhabitant of fairyland. Elf, on the other hand, is of Teutonic origin. It is the Old Eng. *ælf*, entering into the composition of many proper names, as Ælfred; the Ger. *elfe*, the Sw. *elf*, the

Norse *alf*, and is perhaps connected with the Lat. *alb*-us, 'white,' in allusion to their ghostly appearance. F. are imaginary beings of supernatural but limited power, and generally of tiny stature, a belief in whom has been common to almost all countries of Europe. They include beings of very different aspects and qualities. In particular the F. of romance differ from the F. of popular superstition. The former somewhat resemble the Greek nymphs, appear generally as damsels of angelic loveliness, and seduce knights into enchanted isles and palaces. The land of faerie was supposed to be sometimes underground, sometimes amid wildernesses, and sometimes in the ocean. It possessed brilliant but illusory splendours, and mortals were occasionally decoyed thither and detained for many years. Fairy mythology varies with different nations. The *peri* of the Persians, which correspond to the good *jinn* of the Arabs, resemble the *fays* of European romance, being of human stature and exquisite loveliness. They live mostly in the air, and wage war with the *deevs*, or evil spirits. The Scandinavian *alfar*, or elves, were supposed to be partly kind and beautiful, partly malicious, and 'blacker than pitch;' while the *duergar*, or dwarfs, were expert in metallurgy and in forging magical weapons. The English F. are more playful and innocent than those of Scotland and Germany, and appear as graceful, sportive pigmies, fond of dancing at night in the woods, and of sharing in household duties. The English sprite *Robin Goodfellow* corresponds to the German *Knecht Ruprecht*, the Scotch *Brownie*, and the French *Esprit Folet*, or *Gobelin* (goblin). He assumes various forms, misleads travellers, and is constantly playing tricks on mortals. He will sweep the house, and thresh corn at midnight, but if in return a bowl of cream be not set out for him, ill-luck will befall the negligent housekeepers. He is the same as Shakespeare's *Puck* (Old Eng. *pouke*, 'an evil spirit'), and probably as Jonson's *Puck Hairy*. The Cornish *pixies*—according to Keightley a diminutive from *Puck*—are supposed to be the souls of unbaptized children. They dwell in the mines, and, as Will-o'-the-wisps, mislead travellers, whence the term 'pixy-led.' The Scottish F. closely resemble the English. They were said to be small and handsome, to wear green dresses, to ride in splendid processions on Hallowe'en, and to indulge in moonlight revelry, marking the spots where they danced by circles of vivid green called *Fairy Rings* (q. v.). They were fickle and mischievous, kidnapping children to offer as yearly tribute to Satan, stealing the soul from the human body and replacing it by the soul of a fairy, and sometimes carrying away grown-up persons to fairyland. On this last belief are founded the ballad of *Tamlane* (see Scott's *Minstrelsy of the Border*), and Hogg's fine poem of *Kilmeny*. There is an element of sadness and fanciful weirdness in the Scottish tales of F. alien to the kindred English superstitions; thus, the *kelpie*, a wicked Scottish water-spirit, is unknown in the English rivers. The Gaelic F.—called *daoine shi* (dheenè shee), 'men of peace'—were said to inhabit turrets invisible by day but brilliantly illuminated at night. They enticed mortals into their abodes, and if these visitors partook of a fairy banquet, they forfeited the right to return to their fellow-men. According to tradition the Irish F. are the less wicked of the fallen angels, who were permitted to remain on earth. They have various names, apparently derived from *shia*, 'a spirit.' Among them are *pooka*, corresponding to the English *Puck*, who takes the form of a wild colt and indulges in evil frolics; *leprechaun*, a miserly spirit in the form of an old man; the *merrow*, or sea-maid, and the *banshee*, or guardian-spirit of a particular family. The F. of English poetry are different from the F. of popular superstition. Chaucer's F. are partly classic, partly Gothic, having Pluto and Proserpine for king and queen; Spenser's are idealised mortals; and the lovely diminutive spirits of Shakespeare's *Midsummer Night's Dream* are original creations, ruled by Oberon and Titania, who were unknown in the vulgar fairy superstitions. Oberon is *Le Petit Roy Oberon* who figures so conspicuously in mediæval fiction, and holds an intermediate place between the fays of romance and the elves of the north. He is the German Elberich, which the French softened into Oberon. Titania seems a derivative from Titan, since Diana, whom Ovid (*Metamorphoses*, iii. 173) styles Titania, was at one time regarded as a ruler of the F. The name of the tiny queen is thus derived from a word implying colossal stature and strength. Queen Mab, who in a certain degree has usurped the place of Titania, derives her name from the Welsh *mab*, 'a child.' There are frequent allusions to the F. in the Elizabethans, but, next to Shakespeare, Drayton, in *Nymphidia* and the *Poet's Elysium*, has been the most successful poet of fairyland. Fairy-tales became very popular in the last half of the 17th c. The *Contes de ma Mère l'Oye* (1697) of Perrault produced numerous imitations. Among recent authors of fairy-tales Hans Andersen stands unrivalled. See Keightley's *Fairy Mythology* (Bohn, Lond. 1860); Scott's *Essay on the F. of Popular Superstition*, in the *Minstrelsy of the Border*; Grimm's *Haus- und Kindermärchen*.

Fair Isle (Scand. *farr*, 'a sheep'), an island midway between the Orkney and Shetland groups, 29 miles S. by W. of Sumburgh Head, fully 3 miles long and nearly 2 broad, rising into three lofty promontories (one of which, 'Sheep Craig,' gives name to the isle), and accessible only at one point on the N.E. After the defeat of the Spanish Armada in 1588, its admiral, the Duke of Medina Sidonia, retreating northwards, was wrecked on F. I. The inhabitants live mainly by fishing. Pop. (1871) 226.

Fairy Rings, the name popularly given to green spots marked out in pasture lands, from the belief that they represented the meeting-place of fairies and elves. According to Roget, the occurrence of F. R. is explained by the exhaustion of the soil. The dark-green grass of the F. R. has been traced to the growth of fungi which have spread outwards. As the soil becomes deteriorated, the fungi spread themselves further and further outwards, in the form of successive and concentric circles. The succeeding grass crop which grows therein becomes necessarily more luxuriant than the surrounding grass, the soil having been enriched by the decay of the fungi. Way states that fungi which form F. R. (such as *Agaricus oreades* and *A. graveolens*) contain a large quantity of phosphoric acid and potash, which of course tend to enrich the soil.

Fairy Shrimp (*Chirocephalus diaphanus*), a genus of *Crustacea* (q. v.) belonging to a different order from that (*Decapoda*) in which the true shrimps are included—viz., to the order *Phyllopoda* (q. v.). They are so named from their delicate clear appearance. They occur in ponds, &c., in England and elsewhere. Their average length is about 1 inch, yet so clear are their bodies that they can scarcely be detected as they swim back-downwards. They have numerous feet, which are leaf-like in form.

Faith, in the widest sense of the word, is assent to the truth, or the persuasion of the mind that a thing is true. Thus the primary element of it is trust, as the primary idea of truth is that which is trustworthy; and it might be defined as a rational trust beyond the limits of knowledge, but founded upon it. It is often defined as if it were a special organ for the perception of a special kind of truth, but improperly so, although the complex state of mind involved in the act is, of course, different according to the nature of the object of F., and of the evidence on which it is founded. The ordinary definitions of F. may be divided into three classes:—Those founded (1) on its subjective nature; (2) on its object; (3) on its evidence. I. In the first class, F. has been defined as 'a persuasion of the truth stronger than opinion and weaker than knowledge;' otherwise, according to Locke, 'an assent of the mind to propositions which are probably, but not certainly, true;' or, according to Kant, 'the admission of a thing to be true on grounds sufficient subjectively, insufficient objectively.' Secondly, it is said to be a *voluntary* conviction or persuasion of the truth; which definition, however, admits of a number of meanings according to the sense attached to 'voluntary.' Thus it may mean that F. is not merely a speculative assent, but includes feeling; or, that F. does not depend on the nature of the object or the evidence, but on our choice to believe or disbelieve. II. Under the second class, F. is defined as the persuasion of the truth of things not seen. Here, again, 'sight' may be taken in three senses:—(1) Literally; we are said to know a thing which we have seen with our eyes, and to believe in the existence of things of whose existence we are certain, without having seen them. (2) As mental perception; and we are said to believe on testimony what we might afterwards see or know by demonstration. (3) 'Things not seen' may mean all things not present to the mind; and we are said to know only the actual and the present, while what is mediately known, *e.g.*, by memory, is only believed to be. III. Under the third class, F. is defined to be (1) A conviction or persuasion of truth founded on feeling, not because of critical or philosophical

research or of argument, but determined by inclination and inward necessity. (2) F. is a persuasion of the truth founded on testimony, and the F. of the Christian is the persuasion of the truth of the facts and doctrines recorded in the Scriptures on the testimony of God.

Having defined F., theologians further divide it into different kinds:—1. Speculative or dead F. is the F. of those who believe the Bible to be the Word of God, receive all it teaches, and are perfectly orthodox, while yet they may be leading an immoral life. 2. Temporary F. is that temporary impression, more or less deep and lasting, produced by the gospel—*e.g.*, in the apprehension of death—and which is due to those influences of the Spirit of God common to all men. 3. Saving F. is that which makes us the sons of God, and secures eternal life, and is founded 'not on the external or the moral evidence of the truth, but on the testimony of the Spirit with and by the truth to the renewed soul.' See Hodge's *Systematic Theology* (Edinb. 1873).

Faith, Rule of, means a standard by which Christians are to be guided in what they believe in religious matters. The phrase originated with the early Christian fathers, but had a different meaning in the Greek and in the Latin Churches. In the latter, as, *e.g.*, in the writings of Irenæus, Tertullian, Novatian, and Jerome, R. of F. was, in fact, but a name for the Apostles' Creed, which was so called 'because it was the known standard of faith, by which orthodoxy and heresy were judged.' If a man adhered to this rule, he was considered orthodox; but if he deviated from it in any point, he was esteemed a heretic, one who had deserted the common faith and separated from the communion of the Church. In the Greek Church, on the other hand, as, *e.g.*, in the writings of Clement of Alexandria, the R. of F. meant an exegetical tradition or principle, by which the true meaning of Scripture was educed.

In modern times, all are agreed as to the meaning of R. of F. as regards its application, but there is a difference of opinion between Protestants and Roman Catholics as to what constitutes the standard. All Protestants hold that 'the Word of God, as contained in the Scriptures of the Old and New Testaments, is the only infallible rule of faith and practice.' According to Roman Catholics the R. of F. includes Tradition as well as the Scriptures, because 'some doctrines which all Christians are bound to believe are only imperfectly revealed in the Scriptures, others only obscurely intimated, and others not therein contained at all.' With regard to the Scriptures themselves, the Church of Rome differs from Protestants in admitting into the canon certain books which Protestants do not admit to be inspired, namely, the Apocrypha (q. v.). Further, while Protestants hold that the Bible is intelligible by all under the teaching of the Holy Spirit, and that therefore all are entitled and bound to search the Scriptures and judge for themselves what is the true meaning thereof, the Church of Rome teaches that the Bible cannot be properly understood by the people without a visible, present, and infallible interpreter, which interpreter exists in the Church, and the people are therefore bound to believe whatever the Church believes to be the true doctrine. With regard to Tradition, which the Church of Rome also holds to constitute a part of the R. of F., it teaches that many things were taught by Christ and his apostles which were not recorded in the New Testament, but which have been faithfully preserved and transmitted by the Church, and are now to be found, for the most part, in the works of the fathers, decisions of councils, ecclesiastical constitutions, and rescripts of popes. See Davidson's *Sacred Hermeneutics* (Edinb. 1843); Bingham's *Ecclesiast. Antiquities;* Hodge's *Systematic Theology* (Edinb. 1873).

Fai'thorne, Faithorn, or **Faythorne, William,** an English engraver, was born in London about 1625, took up arms for Charles I. in the civil war, was imprisoned, and afterwards went to France, where he seems to have come under the professional influence of Philippe de Champagne and of Nanteuil, and considerably modified his style as an artist. Returning to England in 1650, he entered upon a thriving business as a print-seller and engraver. Among his best portraits are those of Cromwell, Milton, Dryden, Hobbes, Prince Rupert, and Queen Anne (when Princess of Denmark). F., who wrote in 1662 an essay on *The Art of Graveing and Etching*, died May 1691.

Fakir', a name derived from the Arabic *faqutr*, 'poor,' and applied, especially in India, to Mohammedan mendicants who wander through the country, and are universally respected for their sanctity and self-mortification. It does not appear that their austerities have any necessary connection with the Mussulman faith; but they are rather to be derived from the singular spirit of devotion and indifference to pain which has characterised the religions of the East from the earliest times. They bear a close resemblance to the hermits of primitive Christianity, and also to the mendicant friars of later history. In India they are divided into ten classes, named either from their founders, or from a peculiarity of habit or doctrine. Some are jugglers, others dress like women, while others are accustomed to inflict the severest wounds upon themselves without apparent suffering. They travel from one end of the peninsula to another, and have been known to penetrate as far as Europe. In Persia and Turkey this class of holy men is represented by the dervishes. Their counterparts among the Hindus are termed Sanyasees and Byragees.

Falaise' (Fr. 'the cliff-town,' from Scand. *fell* or *felsen*, 'a rock'), a town in the department of Calvados, France, built on a natural terrace close by a rocky height, 23 miles S.E. of Caen. Remains of its ancient walls, and of the castle in which William the Conqueror was born, still exist. Its churches, and many of its houses, recall vividly the middle ages. The chief industry—the trade in leather and furs—which employs 4000 hands, has been carried on for centuries. Pop. (1872) 7634.

Fal'con, the name applied to various genera and species of Raptorial birds, included in the family *Falconidæ* (q. v.). In the typical genus *Falco*, the bill is strong and toothed at its tip. The cere is small, and the nostrils are round, having a central tubercle. The wings have their second and third quills longest, the first and second being notched near the tip. The feathers of the tarsi hang over the knee. The toes are long and powerful, and the talons strong. These birds are among the most typical of the *Raptores*. They exhibit the special structure of that group, and exemplify the bold, wary nature common to the eagles and other forms. The best-known falcons are the Jer or Gyr F. (*Falco gyrfalco*); the Peregrine F. (*F. peregrinus*); the Hobby (*Hypotriorchis subbuteo*); the Lanner (*Falco lannarius*); the Merlin (*Hypotriorchis æsalon*); the Kestrel (*Tinnunculus alaudarius*); the Notched F. (*Harpagus bidentatus*), &c. The name F. is given to various members of the kite sub-family (*Milvinæ*). Thus, the Crook-billed F. (*Cymindis uncinatus*) and Cayenne F. (*C. Cayanensis*) belong to this sub-family. The American Red-throated F. (*Ibycter Americanus*) belongs to the sub-family *Polyborinæ*, and the Rough-legged F. (*Archibuteo lagopus*) to the *Buteoninæ* or Buzzards.

The Falcon.

Falco'ne, Aniell'o, an Italian painter, was born at Naples in 1600, took part in Masaniello's insurrection, afterwards visited Paris, and died at Naples in 1665. Salvator Rosa was one of his pupils. His fame as a painter of battle-pieces was at one time so great as to earn him the title in Italy of 'Oracle of Battles.' His paintings are spirited and natural in design, and brilliant without being glaring in colour. See Lanzi's *Storia della Pittura*, vol. ii.

Fal'coner, William, an English poet, born at Edinburgh, 11th February 1732; entered the merchant service; and when eighteen became second mate of a vessel which was wrecked (1750) off Cape Colonna, F. and two others alone being saved. This disastrous voyage is the subject of F.'s *Shipwreck*. Through the influence of the Duke of York, to whom the *Shipwreck* (1762) was dedicated, F. joined the navy in 1763, and was lost at sea, when purser of the *Aurora* frigate, in 1769. The *Ship-*

wreck has passages of vigorous and pathetic description, but is essentially commonplace in structure and idea; while the contrast between F.'s frequent nautical technicalities and the names and conversation of his characters, who seem borrowed from a Queen Anne pastoral, jars upon the reader, and lessens the interest. F. wrote several verses of circumstance deservedly forgotten; *The Demagogue* (1765), an attack on Wilkes and Churchill; and a *Universal Marine Dictionary* (1769). The once popular song, *Cease, rude Boreas*, has also been attributed to him. See the Memoir by Stanier Clarke prefixed to his edition of the *Shipwreck* (1804), and that by Mitford in the Aldine edition of F.'s *Poetical Works* (Bell & Daldy, Lond. 1870).

Falcon'idæ, a large and well-known family of Raptorial birds, the members of which are distinguished by the fact that the bill has a partial cere, and is of compressed form, having the keel curved from the cere to the tip. The wings are long and pointed, and the tail broad. The tarsi are varied and of strong make, the claws being curved and sharp. The head and neck are feathered, and the eyes appear sunk and overarched by the brow. This family includes several well-marked sub-families. Chief of these are the *Aquilinæ* or Eagles (q. v.), the *Polyborinæ* (including the Caracaras and Brazilian kites), the *Buteoninæ* or buzzards, the *Milvinæ* or kites, the *Falconinæ* or falcons proper, and the *Accipitrinæ* or sparrow-hawks, &c. The F. are found in all parts of the world.

Fal'conry or **Hawk'ing**, the art of training Falcons (q. v.) and birds of Raptorial kind to pursue other birds in flight and capture them. The practice of F. dates from a remote period. It was probably derived from the East, and was most in vogue in England during the middle ages. The birds chiefly pursued as game were the heron, partridge, lark, pigeon, wild-duck, &c. The falcons used in the sport were the Peregrine (q. v.) and Gyr-Falcon (q. v.); but the Goshawk (q. v.) and Sparrow-Hawk (q. v.), birds of less powerful flight than the two former species, were also employed. The female birds, as a rule, were most valued by the falconer. They seemed to possess powers of endurance, agility, and cunning wanting in the males. The species which was most in favour was the peregrine falcon, which, when taken early from the nest and trained to the sport, excelled the other species in dexterity, and in the readiness with which it lent itself to the exercise. The course of training undergone by these birds was of a very complete and lengthy character. The falconer preferred to take the bird from the nest, but his art was, in lieu of nestlings, also practised on older birds. The young or nestling was named the *eyess*, and on being taken from the nest was carefully tended by the falconer, and was lodged in some outhouse, being fed on flesh of various kinds. Becoming thus familiarised with man, the *eyess* grew tamer. The food was generally attached to a *lure*—an apparatus consisting of a bunch of feathers, a cord, and tassel. The object of thus feeding the falcon was to accustom it to recognise the lure, and to associate it with its food; this association afterwards serving to recall and entice the bird to the falconer when its chase was unsuccessful. Another form of lure was that known as the *tabur stycke*, consisting of a short stick on which the semblance of a bird was borne; and a third form of lure was named the *drawer*. As the bird's powers of flight became developed, the lure was used to entice her back to hand after permitting her to fly abroad. The operation which was most important in the falcon's training is that known as *hooding*. This consisted in placing on the bird's head a close-fitting leather cap, made so as to cover the eyes, but to allow the protrusion of the beak. This procedure often repeated had the effect of making the bird tame and docile. The bird thus hooded was set on a 'block' of wood, and was secured thereto by an apparatus of *bells* and *jesses*; the former being two hollow metal globes attached by *bewits* or leather straps to the legs of the bird; whilst the jesses were leather bands 5 or 6 inches in length, and fixed to each leg below the bells. The jesses, in turn, were attached to another strap—the *leash*—by means of *varvels*, or two rings of silver, on which the owner's name was engraved. The apparatus thus described ultimately became permanent parts of the falcon's harness; and in addition to these structures, a long cord, named the *creance*, was tied to the leash, and served to afford further and wider scope to the movements of the bird in training. It was also trained to sit or perch itself steadily on the hand of its master or mistress. The falcon was further taught to circle and hover round the falconer, the lure being made use of to this end. The bird mostly pursued of old was the heron. The prey or *quarry* was attacked in its homeward flight against the wind. The falcons being unhooded, were cast off, and sought a greater elevation than the prey, on which they successively *stooped* or *swooped* down. If the first missed its aim, the second hawk *stooped* in like manner, the heron being soon seized. The falconer drew off the hawks from the prey after all three had descended, luring them by means of live pigeons and other birds. The heron was rarely killed outright, but was frequently liberated, being first marked with the name of the falcon's owner. It often proved a powerful adversary while on the ground, striking at the falcons with its powerful beak, and sometimes transfixing them. The Merlin (q. v.) is chiefly used for the capture of larks and other small birds, and the goshawk may be employed to secure pheasants, and even rabbits and hares. A special terminology, of which some examples have been given, characterised the sport. The most celebrated training-place for falconers was the village of Falconswaerd, near Bois-le-Duc, in Holland. Several old and a few modern treatises exist on F.; the best-known of the latter is Freeman and Salvin's *Falconry*, published in 1859.

Faler'ii, an Etruscan city, W. of the Tiber, and N. of Mount Soracte. It first appears in Roman history (B.C. 437) as the enemy of Rome, and after the fall of Veii it was besieged by the Romans under Camillus, whose treatment of the treacherous schoolmaster is a familiar fable. The friendly relations then established with Rome were broken on several occasions, and finally (B.C. 241) the inhabitants (called *Falisci*) were expelled from their old city and founded a new one, on whose site the 'Colonia Falisca' was subsequently established by the triumvirs. In the middle ages another city, named *Civita Castellana*, appeared on the site of the old F.

Faler'nian Wine occupied the second rank among the ancient wines of Italy. It was produced in a district of Campania, stretching from the Massican Hills to the river Vulturnus, and known as the *Falernus Ager*. The best variety was the *Faustianum*.

Falie'ri, an ancient Venetian family, several members of which held high offices in the state, and one of whom took part in the election of the first doge in 697. The most notable, however, was **Marino F.** He was born about 1284, and at the siege of Zara in 1346 defeated 80,000 Hungarians, at the same time checking the besieged. Appointed commander of the fleet, he took Capo d'Istria, and afterwards, while absent as ambassador at Rome, was chosen doge in 1354. In the following year, enraged because the Council of Forty passed what he thought too slight a sentence on a nobleman, Michele Steno, who had libelled the doge's young wife, F. conspired to overthrow the republic and win the sovereignty. The plot was betrayed, and the chief conspirators were executed. F. was beheaded, 17th April 1355, on the stone staircase where the doges took the oath after election. F. seems to have been brave, violent, and unforgiving. He was a personal friend of Petrarch, who mentions him in his letters. Among the pictures of the doges in the hall of the Grand Council is a space veiled and inscribed 'Hic est locus Marini Faletro, decapitati pro criminibus.' See Byron's *Marino F.* and its appendices, and Marino Sanuto's *Vite de' Duchi de Venezia*.

Fal'kirk (perhaps 'the kirk on the *Vallum*' or wall of Agricola; the Gaelic name is *Eglais-bhrac*, 'the speckled kirk'), a town of Stirlingshire, Scotland, 22 miles E.N.E of Glasgow, and 25 W. by N. of Edinburgh, and a station on the N. British Railway. It is in the immediate vicinity of extensive ironworks, of which the best known are the Carron, which have given name to a peculiar kind of ironmongery, and to a piece of ordnance known as a carronade, because both are made at Carron. Several firebrick, tile, and chemical works are in the neighbourhood. F. has also three famous trysts or cattle-fairs, known by its name. Two battles have occurred in the neighbourhood, the first in 1298 between the troops of Edward I. and the Scotch under Wallace, in which the latter was completely defeated; and the second between the royal forces and those of the Chevalier, Prince Charles Edward Stuart, in 1746, in which the former were repulsed. F. became a royal burgh in 1646. Along with

Airdrie, Hamilton, Lanark, and Linlithgow, it sends one member to Parliament. Pop. (1871) 11,762.

Falk'land, an ancient burgh of Scotland, Fifeshire, 10 miles S.W. of Cupar, its charter dating from 1458. (Pop. 1871) 1283, mostly hand-loom weavers. F. Palace, a famous royal residence, has given distinction to the place. It is mentioned by Sir David Lyndsay in his *Complaynt of the Papingo* as the 'forteress of Fyfe.'

Falkland Islands, otherwise the **Malouines'** or the **Malvi'nas**, an archipelago in the S. Atlantic belonging to Britain, and lying 230 miles E. of Magellan's Strait. They consist of two large islands, E. and W. F., and of about 200 smaller, with an area of 4741 sq. miles, and a pop. (1871) of 803. They were discovered in 1593 by Richard Hawkins, but it is only since 1833 that they have formed a British settlement, though they have been a British possession since 1771. Previously they had belonged in succession to France and Spain. These islands are principally valuable from their numerous commodious harbours. The pasturage is good and the surrounding seas teem with fish; seals also abound. Stanley, in E. F., is the seat of the government.

Falkland, Lucius Cary, Viscount, was born at Burford, Oxfordshire, in 1610. His father, Sir Henry Cary, filled for a time the post of deputy-lieutenant in Ireland, and F. was educated at Trinity College, Dublin, and St John's College, Cambridge. Inheriting from his grandfather an estate worth £2000 a year, he devoted himself to learned research, and was on terms of friendship with such men as Selden and Chillingworth. In 1640 he entered the House of Commons as member for Newport, in the Isle of Wight, and at first took an active part on the side of Hampden and Pym, and against the illegalities of the king and his tools. Ultimately, however, he separated from the popular party. After a vain attempt at mediation between king and Parliament, he espoused, though with sad forebodings, the side of the former in the civil war, fought gallantly at Edgehill, and fell in the first battle of Newbury, September 20, 1643. He was an author both in prose and verse, his best-known work being a *Discourse on the Infallibility of the Church of Rome.* Green, in his *Short History of the English People*, p. 525, finely describes him as 'the centre of a circle which embraced the most liberal thinkers of his day, a keen reasoner and able speaker, whose convictions still went with the Parliament, while his wavering and impulsive temper, his love of the Church, his passionate longings for peace, his sympathy for the fallen, led him to struggle for a king whom he distrusted, and to die in a cause that was not his own.' See Forster's *Historical and Biographical Essays* (1858).

Fall, The, is the name given by theologians to the sin committed by our first parents in disobeying the command of God and eating of the forbidden fruit in the garden of Eden, as described in the third chapter of Genesis. The details of that narrative, which are familiar to every one, have always been interpreted by theologians with a greater or less departure from the literal sense. Thus the ordinary interpretation is that the serpent was only a figurative designation of Satan, or actually Satan in disguise, or, at least, that the serpent, if real, was employed by Satan as his organ or instrument. According to this view, the effects of the disobedience recorded in the narrative were merely subordinate expressions of the divine displeasure, and consequences of that which was the real and primary effect, namely, spiritual death or absolute ruin analogous to that of the fallen angels; so that the F. is the very basis of the whole system of Christian theology, necessitating, as it does, the Atonement, which indeed is obscurely predicted in the words of God to the serpent:—'It (the seed of the woman) shall bruise thy head, and thou shalt bruise his heel.' Others, however, regard the serpent of the narrative as a real animal, but the narrative itself as a fable or allegory intended to explain philosophically the origin of evil, physical and moral, in which allegory the tree of Life represents spirituality, the tree of Knowledge sensuality, the serpent being the symbol of pleasure. According to this view, which has been held by some of the learned from the earliest times, *e.g.*, Philo, Clement of Alexandria, Origen, Eusebius, Augustine, &c., the allegory teaches 'that as soon as man's mind, through the weakness and treachery of his senses, became captivated and seduced by the allurements of lust and pleasure, he was driven by God out of Paradise, that is, lost and forfeited the happiness and prosperity which he had enjoyed in his innocence.' For the theological bearings of the F., see ORIGINAL SIN.

Traditions of a F. from a state of original innocence and happiness are to be found among every nation possessing a cosmogony and theogony. According to the Hindus, the first man was tempted by the Supreme Being, whose special symbol was the serpent, by means of a blossom dropped from heaven of the sacred Indian fig. Instigated by his wife, who had derived her being from him, the man determined to possess the blossom, with the expectation that it would make him immortal, and on gathering it actually believed himself to be so; but, on the appearance of the deity, the pair were banished from the Paradise in which they were. The Persian account, contained in the Zend-Avesta, is as follows:—'The first couple lived originally in purity and innocence. Perpetual happiness was promised to them by Ormuzd, the creator of every good gift, if they persevered in their virtue. But an evil demon was sent to them by Ahriman, the representative of everything noxious and sinful. He appeared unexpectedly in the form of a serpent, and gave them the fruit of a wonderful tree, Hom, which imparted immortality, and had the power of restoring the dead to life. Thus evil inclinations entered their hearts; all their moral excellences were destroyed. Ahriman himself appeared under the form of the same reptile, and completed the work of seduction. They acknowledged him instead of Ormuzd as the creator of everything good, and the consequence was that they forfeited for ever the eternal happiness for which they were destined.' A likeness has been remarked between the Greek myth of the garden of the Hesperides—in which was a tree with golden apples, guarded by a speaking dragon, the possession of which conferred immortality—and the story in Genesis; for which also some of the designs might stand as illustrations which appear on the ancient Greek gems and Etruscan pottery. To account for the similarity existing among all these traditions one school of divines supposes them all to have been derived from the Hebrew Scriptures, the oldest literature in existence; another school holds the theory that the Jews derived their literature on the early history of the human race from the Babylonians and Persians, during their captivity in Babylon. The latter view has lately received apparent confirmation from the discoveries of Chaldæan literature made by Mr. G. Smith. On the terra-cotta tablets dug from the ruins of Assyrian cities by himself and others, he has discovered accounts of the creation, F., deluge, &c., corresponding almost exactly, as far as the narrative on the tablets yet found goes, with those in Genesis, except that they are fuller. See Kalisch's *Commentary on Genesis*; C. Middleton's *Works* (2d ed. Lond. 1755); G. Smith's *Chaldæan Account of Genesis* (1876).

Fall'acy (Lat. *fallacia*) is the technical name given in logic to an error which arises not in observation by the senses, but in reasoning, or in the interpretation of what is directly seen. The line between fact and inference, between the original sense-impression and the form and colour which it receives from the mind, is no doubt hard to trace. A great many unapparent details are filled in unconsciously, and therefore the leading rule of all scientific inquiry is to remove, or minimise, or allow for your errors of observation. It is a F. to omit observation altogether, or to unduly limit its range; but every F. assumes a fact truly ascertained, which the mind then proceeds to distort. Fallacies might, therefore, be classified according to the particular kind of reasoning, inductive or deductive, in which they occur. In books on formal logic, where alone syllogistic reasoning is (at least, properly) treated, they are classified according to the canon of consistency violated. Elsewhere, as in Bentham's *Book of Fallacies*, or Bastiat's *Sophismes Économiques*, the leading errors on a particular subject are collected and analysed. But before we reach fallacies of inference or reasoning, there is (1) A class of natural prejudices, called by Mr. Mill 'fallacies of simple inspection,' which are held by the mind as self-evident, *i.e.*, without conscious reference to evidence. The strength of these prejudices often depends on the feelings as a remote predisposing cause, but the form of intellectual error is much the same in all cases, viz., that the course of nature must correspond to the current of human thought.

Under this class come most cases of omens, unlucky days or names, &c. Similar fallacies, however, may be found in philosophy and in cultivated opinion—*e.g.*, things we cannot think of apart must exist together, and things which we cannot think of together cannot coexist; every clear idea must correspond with an object—a principle at the root of the systems of Descartes, Spinoza, and Leibnitz; a thing can act only where it is; nature always works by the simplest means; the belief in the separate existence of abstract qualities or class names; the principle of sufficient reason, according to which nature does a certain thing because man can see no reason why she should not; the idea (held by Bacon) that there must be only *one* cause of the sensible qualities of objects; or that entertained by many metaphysicians, that the conditions of the phenomenon must, or probably will, *resemble* the phenomenon itself, exemplified in the medical doctrine of signatures, that the virtue of every substance is pointed out by some external character. (2) Another important class of fallacies is called by Mr. Mill 'fallacies of observation,' which consist in either *non-observation* or *mal-observation*. The mind is moved by the marvellous, and is also biassed by preconceived opinion or the desire to establish a particular conclusion. Hence comes a disposition not to observe, as in the famous Copernican dispute about the stone falling from the ship-mast. Or where a particular instance is examined, material circumstances may be overlooked, *e.g.*, the phlogistic theory, in which the gaseous products of combustion were overlooked. Mal-observation arises for the most part from the tendency above alluded to to confuse perception with inference, or sensation with judgment. (3) Fallacies of *generalisation*, in which inferences are drawn from the order of things in the known to that in the unknown universe, *e.g.*, the attempts made to analyse into one things generically distinct, as heat, light, and sensation into motion; the 'induction by enumeration,' or *per enum. simplicem*, of the ancients. A more special form is that called in formal logic *post hoc ergo propter hoc*, where a true cause is inferred from casual conjunction, as in the line of political reasoning which justifies existing institutions from the contemporaneous prosperity of the commonwealth. Common language is saturated with metaphor, especially with subtle exchanges of meaning between the bodily and the spiritual, and it is difficult to state a proposition on any complex subject without tacitly suggesting several very questionable trains of thought. (4) Fallacies of *ratiocination*, or what are generally given in works on formal logic. These include wrong conversion of universal affirmative and of hypothetical propositions. It is constantly supposed that, because the premisses cannot be true if the conclusion is false, therefore the premisses cannot be false if the conclusion is true. In the opposition of propositions, too, it is often forgotten that contrary propositions, though they cannot both be true, may both be false. The ordinary syllogistic fallacies all consist in having more than three terms, either expressly or by undistributed middle or *illicit process* of extremes. Frequently the premisses are changed in argument, as in the scholastic *a dicto secundum quid ad dictum simpliciter*, an absolute rule is substituted for one qualified. Examples of this are the mercantile theory in economics (which left out of view in its conclusion the purchasing power of money), and the argument that tithes fell on the landlord because, *under the tithe system*, the owner of tithed land received less than the owner of tithe-free land. (5) Fallacies of *confusion*, which include all those fallacies that consist not so much in mistaking the force of evidence, as in an indistinct notion of what the evidence is. The chief is the F. of an ambiguous middle, where the middle term of a syllogism is ambiguous, or one of the syllogistic terms is taken in one sense in the premisses, and in another sense in the conclusion. Etymology in this way becomes a prolific source of erroneous reasoning. In the F. of composition and division something is established separately concerning each *single* member of a certain class, and then the same is inferred of the whole *collectively*. The *petitio principii*, or reasoning in a circle, occurs where the premiss is the same as the conclusion, or can be proved from it alone. It is quite common, when discussion does not run to first principles, to prove A by B, though B really depends on A for proof. The conclusion, abstractly stated, often serves for a premiss, and the words nature and essence are very useful in this connection, and what Bentham calls 'question-begging appellatives,' *e.g.*, innovation. The *ignoratio elenchi* consists in the establishment of an irrelevant conclusion, a particular for a universal, or some proposition which excites the feelings. See the treatises on logic by Whately, Mill, De Morgan, and Sir William Hamilton.

Fall'en Angels. It appears from certain passages of Scripture that some of the angels 'kept not their first estate' (Jude 6), but 'sinned' and were 'cast down to hell' (2 Pet. ii. 4). The Apocalypse, with greater minuteness, tells that the archangel Michael and his angels made war against the dragon (Satan) and his angels, and prevailed, and the dragon was cast out, and his angels were cast out with him (xii. 7-9). These F. A. are thus the Demons (q. v.) who are so ready to obey the behests of their master the Devil in afflicting mankind, although St Jude and St Peter speak of their being bound in chains till the judgment day. It also appears from Eph. i. 21, vi. 12 (*cf.* iii. 10, Col. i. 16, 1 Pet. iii. 22), that the same grades existed among them as among those who had not fallen. As to the nature of the sin which led to their fall, various opinions have been held. Some have thought it was lust, founding on Gen. vi. 2; others, envy; but it is generally held to have been pride, from 1 Tim. iii. 6.

It is asserted by some, however, that all this doctrine of the Devil and his angels was derived by the Jews from the dualistic ideas of the Babylonians and Persians, during their Babylonian exile (see DEVIL), and that the allusions to the F. A. in the New Testament are derived from the Book of Enoch (q. v.), in which the following passage occurs:—'To Michael also the Lord said, Go, and announce his crime to Samyaza and to the others who are with him, who have been associated with women. . . . Bind them for seventy generations underneath the earth . . . until the judgment which will last for ever be completed. Then shall they be taken away into the lowest depths of the fire in torments, and in confinement shall they be shut up for ever' (x. 15, 16). Be that as it may, the Babylonians had fuller traditions than the Jews about the fall of the dragon and his angels, as appears from recently discovered Chaldæan literature. See G. Smith's *Chaldæan Account of Genesis* (Lond. 1876); *Book of Enoch.*

Fallmeray'er, Philipp Jakob, a German historian and traveller, was born of poor parents at Tschötsch, near Brixen, in Tyrol, December 10, 1791. He studied at the universities of Salzburg and Landshut, devoting himself chiefly to history and philology. After serving in the Bavarian forces against Napoleon, he was made a master in the gymnasium at Augsburg, and afterwards held the chair of philology at Landshut. From 1831 to 1834 he travelled in Egypt, Palestine, Syria, and Greece; and in 1840, and again in 1847, visited the East. He was elected to the Frankfurt Assembly, but shortly retired from public life. He died at Munich, April 26, 1860. Among his works are *Geschichte des Kaiserthums Trapezunt* (1831); *Geschichte der Halbinsel Morea im Mittelalter* (1830-36); *Fragmente aus dem Orient* (1845). His *Gesammelte Werke* were edited by Thomas in 3 vols. (Leips. 1861).

Falling Bodies. See PROJECTILES.

Falling Sickness. See EPILEPSY.

Fallo'pius, Gabrie'le, a famous anatomist, was born at Modena about 1523. He studied science in various universities throughout Europe, and in 1551 became professor of anatomy at Pisa. He died in 1562. F. was one of the earliest restorers of anatomy, but several discoveries claimed by him have been traced to Greek and Arabic physicians,—*e.g.*, the two tubes leading from the ovary to the Uterus (q. v.) were not discovered by him, though called the *Fallopian tubes*, having been accurately described by Herophilus and Rufus of Ephesus more than 300 years B.C. Among F.'s works are *Observationes Anatomicæ* (1561), *De Thermalibus Aquis* (1564), *De Morbo Gallico Tractatus* (1564), &c. See the collected edition of his works, entitled *Opera genuina omnia, tam practica quam theoretica* (Ven. 3 vols. 1584; Frankf. 4 vols. 1600).

Fallopius, Aqueduct of, a canal in the fibrous portion of the temporal, which transmits the facial nerve. It passes outwards and backwards over the labyrinth of the Ear (q. v.), and terminates at the stylo-mastoid foramen. On the anterior and upper surface of the bone there is a small foramen named the *hiatus Fallopii*, which transmits the large superficial petrosal nerve.

Fall'ow (Old Eng. *fealo*, a pale or reddish yellow; *cf.* Ger. *falb* and *fahl*, allied to Lat. *fulv*-us), a term in agricul

ture applied to land left bare of any crop for a season to free it from weeds, and to improve the mechanical condition of the soil. The practice of fallowing is one of very ancient origin, having been inculcated in the Mosaic law, which commanded that the ground should rest every seventh year. It was well known to the ancient Romans, by whom fallowing was introduced into England; but it was not till about the beginning of the 18th c. that the practice was begun in Scottish agriculture. Originally all kinds of land were fallowed indiscriminately; but the introduction of green crops, such as potatoes and turnips, had the effect of greatly limiting the area of land to which the system was applied. Now what is termed 'bare or summer F.' is only applied to very stiff retentive clay soils such as are found in the 'carse' land of Scotland, the fen clays of Huntingdon and Cambridgeshire, and the weald clay of Kent and Sussex in England. On the lighter soils, the periodical cultivation of green crops effects the same object, and is known as 'green-crop F.' Land under bare F. is ploughed up immediately on the removal of the crop, and so exposed to the rains, frosts, and atmospheric influences of the winter. In spring it is again ploughed across, and on very stiff soils it may receive as many as six or eight ploughings, besides scarifying and harrowing throughout the season. The soil so treated is thoroughly exposed to the oxidising influences of the atmosphere, and to the action of the carbonic acid contained in the air, as well as that dissolved in every shower of rain. While the land is thereby rendered more mellow and friable, the mineral substances which enter into the constitution of cultivated plants are fitted for assimilation, and injurious weeds are at the same time thoroughly eradicated.

Fallow Chat. See WHEATEAR.

Fallow Deer (*Dama vulgaris*), a species of *Cervidæ* or Deer (q. v.) nearly allied to the Stag (q. v.), but distinguished by its spotted coat, its smaller size, and the spreading palmated horns. The colour of the F. D. is a reddish brown spotted with white, and usually exhibiting a few whitish lines on the body. In winter it assumes a darker tint. The average height is about 3 feet at the shoulders. The food consists of grasses of various kinds. The original habitat of the F. D. is unknown. Tradition points to S. Europe or W. Asia as its probable home; but it is rarely if ever met with save in a domesticated state. F. D. are largely kept in parks and grounds. They are very docile, and readily tamed, the herd being governed by a 'master deer.' The flesh affords good venison, and from the skin leather is manufactured; while the shavings of the horns are used in making ammonia—hence popularly named 'hartshorn.' The females are hornless. The young are named *fawns*, the females *does*, and the males *bucks*.

Fallow Deer.

Fall River, a city of Massachusetts, U.S., at the mouth of a stream of the same name and of the Taunton River, 20 miles from the sea, and 48 S. of Boston by railway. It has two calico printworks, one woollen factory, thirty-eight cotton mills, having 1,269,788 spindles, large ironworks, and a bleaching business. It has also deep-water navigation, and is the terminus of steamboat communication with New York. It possesses a free library, a public park of 60 acres, two daily and three weekly newspapers, &c. Pop. (1870) 26,766. F. R., which was founded in 1659, was incorporated as a town in 1803, and as a city in 1854.—F. R., a small stream in Massachusetts, of great utility for its water-power. In its last half mile it descends about 130 feet, its banks being lined with extensive mills. It enters the eastern arm of the Narragansett Bay.

Fal'mouth, a town of Cornwall, England, at the mouth of the Fal, and formerly a station for the packet-boats to the S. of Europe and the W. Indies, 92 miles S.W. of Exeter and 266 W.S.W. of London. It is connected with Plymouth by the Cornwall Railway. The harbour, which is of unusual depth and capacity, is defended on the E. and W. respectively by St. Mawes and Pendennis Castles, built by Henry VIII. and strengthened by Elizabeth. The number of vessels that entered in 1875 was 1010; tonnage, 140,614; cleared, 589; tonnage, 49,167. The chief exports are tin, copper, granite, and fish (pilchards, oysters, &c.); the chief imports are timber, grain, flour, wine, hemp, fruit, and guano. Pop. (1871) of the municipal borough, 5294. F., with Penryn, returns two members to Parliament.

False Bay, a capacious inlet of the Southern Ocean in Cape Colony, S. Africa, the S.W. boundary of which is formed by the Cape of Good Hope It is about 22 miles long, and as many broad. Being protected from the N.W. monsoon, it has been chosen as the station of the British fleet in S. African waters.

False'hood, Le'gal, is defined to be a fraudulent imitation or suppression of truth to the injury of any one. *Forgery* and *swindling* are the main branches of the crime. See these articles; also FRAUD.

False Impris'onment consists in the unlawful detention of the person. All forcible confinement, even in a street, is by the law regarded as imprisonment. Legal restraint of the person must be by warrant of a court of law or legal officer, or by special power warranted by statute or common law, such as the obligation on every man who sees an act of felony committed to arrest the felon. (See APPREHEND.) F. I., however, may arise from executing a legal process at an illegal time, as by arresting in a civil process on Sunday. The imprisonment being committed under error is no excuse. The corresponding Scotch law term is Wrongous Imprisonment (q. v.). In England the safeguard of the subject is his power to require a court of law to issue in his favour a writ of Habeas Corpus (q. v.) *ad subjiciendum*.

False Point, a harbour at the mouth of the Mahanuddee river, in the district of Cuttack, province of Bengal, British India, 196 miles S. of Calcutta. In 1860 it was first formed into a port, though a lighthouse had been previously erected and buoys laid down; it now ranks as the third harbour of Bengal. Ships cannot proceed up the river, but native boats now bring down produce from the town of Cuttack through the Kendrapara Canal. In 1874-75 110 ships entered; tonnage, 118,375; value of the imports, £118,395; of the exports, chiefly rice, £170,047.

False Pretences, Obtaining Money by. To constitute this offence there must be a specific fraudulent misrepresentation of matter of fact by which property is obtained. If a man purchase goods, promising to pay for them next day or on some other specified day, should he fail to do so the failure is merely in an engagement. But if he obtain the goods in exchange for a cheque on a banker, stating falsely that he has funds in hands of the banker to meet the cheque, he commits the crime in question. But in a case in which a man induced a banker to pay his cheque by drawing a bill on one on whom he had no right to draw, the act was adjudged not to be a false pretence because he only obtained credit. It would have been otherwise had he obtained money on the bill. The distinction is a fine one, and obtaining credit by fraud is now punishable under the Bankrupt Act of 1869. The 24 and 25 Vict. c. 96 consolidates previous legislation on the subject. A minor obtaining money or goods by pretending to be of age may be punished as a common cheat. Under the Act, any one fraudulently inducing another to sign his name or to execute any document is guilty of felony; and liable to three years' penal servitude. Bills of exchange and all negotiable securities are included under this provision.

In Scotland the crime in question is punishable under common law. See FRAUD, SWINDLING.

False Return, Legal, renders the officer who makes it liable in damage.

False Swearing. See PERJURY, AFFIRMATION, DECLARATION. Under the English Bankruptcy Act, if the bankrupt make a false declaration, he is guilty of perjury. Under the Scotch Act, any one under oath is liable to prosecution at the instance of the Lord Advocate, or of the trustee in the sequestration, with concurrence of the Lord Advocate.

Falsett'o, a high register possessed by many male voices. It is seldom agreeable in itself, or used in serious concerted music.

False Verdict may arise from improper behaviour of the jury among themselves, or of the plaintiff towards them, by which their verdict is influenced, from misdirection of the judge, or from exorbitant award of damage. On these and similar grounds a new trial may be granted. But if two juries return the same or a similar verdict, a third trial is seldom conceded. Formerly, in England, a juror returning a F. V. might in certain circumstances incur heavy penalties under a writ of attaint, but the process was abolished by 6 Geo. IV. c. 50, and the universal rule now is that a juryman cannot on any ground be punished for his verdict.

False Weights and Measures. Possession of these for purpose of trade is in England punishable under common law. The penalty is imprisonment. In Scotland the users of false weights are by statute liable to confiscation of movables.

Fal'sifying Rec'ords. Any one injuring or obliterating any original document in legal process is liable to be punished with penal servitude. And any official whose business it is to furnish certified copies of documents, wilfully certifying a false copy is guilty of felony, and is liable to the punishment of penal servitude for life.

Fal'ster, a Danish island in the Baltic, 2½ miles S. of Seeland, and included in the amt of Maribo. Area, 181 sq. miles; pop. (1874) 32,413. It is flat, low, and rather unhealthy, but yields much corn and timber, and is celebrated for its fruits. Nykjöbing, the capital (pop. 3645), is on the Guldborgsund, and has a cathedral, castle, and some trade. F. became a royal domain in the 16th c., and was the chief residence of several Danish queens, of whom the last was Charlotte Amalie, 1700–14.

Fa'lun, or **Fah'lun** (otherwise *Gamla Kopparberget*, 'the old copper-mine'), the capital of the 'län' Stora Kopparbergs, Dalarna, in Sweden, in a valley between lakes Warpan and Runn, 120 miles N.W. of Stockholm by railway. It has long been famous for its copper-mines, which are now, however, much less profitable than of yore. The mines were formerly the most extensive of the kind in Sweden, and indeed in the world. About the middle of the 17th c. the yield was 3000 tons; at present it is barely 700 tons. Since 1716 they have been in the hands of a joint-stock company, who own from sixty to seventy smelting furnaces. The smoke from these has given the town a dingy appearance. F. has also a mining-school and museum, cotton and flax mills, besides manufactures of cow-hair cloth, leather, tobacco, nails, &c. Pop. (1876) 6741.

Fa'ma (Lat.; Gr. *Phêmê*, or *Ossa*) was the personification of rumour or report. She is called by various ancient poets the messenger of Zeus, the daughter of Hope, and the daughter of Terra.

Fa'ma Clamo'sa in the ecclesiastical law of Scotland is a prevailing report imputing immoral conduct to a clergyman, probationer, or elder of the Church. No process is begun by the presbytery unless the F. C. be so clamant as to make it necessary to do so for their own vindication, or unless a complaint has been formally given in.

Famil'iar Spir'its is a name in which three different shades of meaning may be traced, or perhaps there have been three stages in the development of the idea expressed. 1. F. S. were originally the shades or ghosts of deceased persons brought up by magical arts from the abode of the dead, which, according to all ancient ideas, was in the bowels of the earth, in order that they might give information about future or doubtful things. This is necromancy pure and simple, and is well seen in the episode of the witch of Endor, to whom Saul said, 'Divine unto me by a familiar spirit, and bring me up whom I shall name unto thee' (1 Sam. xxviii. 8). The term familiar spirit has the same meaning in Isa. viii. 19, where the prophet asks, 'Why inquire at the dead concerning the living?' The shade of Samuel appears to have been seen by the witch; generally, however, the F. S. appeared to speak out of the ground: *cf.* Isa. xxix. 4, 'Thy voice shall be as of a familiar spirit out of the ground.' 2. Again F. S. were demons (in the original sense of disembodied spirits not necessarily evil) who took up their abode in the bodies of the magicians, who revealed matters communicated to them by the F. S. The persons so possessed were called by the Greeks *engastrimythoi* ('ventriloquists'), doubtless because designing men often imposed on people by means of the faculty of ventriloquism, and made sounds appear to come from their belly or breast, as well as from the ground. Isa. viii. 19 ('those that chirp and whisper') alludes to their imitating the chirping of bats. It is the name given in the LXX. to those having F. S., distinguishing them, as in Deut. xviii. 11, from necromancers, although, on the other hand, the term is also applied to the witch of Endor (1 Sam. xxviii. 7). They were also called *Pythones*, which is the term used Acts xvi. 16—'a spirit of Python.' 3. The third stage in the development of the idea was when demons came to be regarded by the Christian Church as altogether evil. Tertullian, in his *Apology for the Christians*, describes them as being 'everywhere in a single moment; the whole world is as one place to them; all that is done over the whole extent of it, it is as easy for them to know as to report. . . . The purposes of God, too, they took up of old from the lips of the prophets, even as they spoke them; and they gather them still from their works when they hear them read aloud. Thus getting, too, from this source some intimations of the future, they set themselves up as rivals of the true God, while they steal his divinations.' See DEMONS, NECROMANCY, and WITCHCRAFT.

Familiars. See INQUISITION.

Fam'ily. The word F. is derived from the Latin *familia*, and this from the Oscan *famal*, 'a servant,' or *faama*, 'a house.' This last corresponds to the Sanskrit *dhâman* (*cf.* Lat. *domus*), 'house,' from the radical *dhâ*, 'to place.' At Rome the primitive meaning of *familia* was the number of slaves or servants belonging to a person or a public office; then all those, whether masters or slaves, living under the same roof; lastly, all those connected by blood, whether living together or not. Its general meaning now is those persons connected by blood who live together, *i.e.*, father, mother, and children. But it has numerous other meanings. It is applied to the establishment of a cardinal, to the human race, to the children apart from the parents, to a political dynasty, to a religious order, to a group of organisms in botany or zoology, to a group of substances in chemistry, of allied words in philology, or of surfaces or curves in geometry having analytical or other properties in common. The legal conception of F., implying various reciprocal obligations and duties between parents and children, has been the subject of many theories. By one, the children became the property of the parents; by another, there was a tacit convention between parent and child; by a third, burdens were placed on the parents as a punishment for having sinned in bringing into existence creatures incapable of supporting themselves. Board, nourishment, education, are among the obvious positive obligations of parents; they, in turn, have a claim for support upon their children in case of old age and destitution. The limits and pecuniary amount of these obligations are of course varied by different municipal laws. The character of a nation, and the general laws which govern society, depend to a large extent on the kind of families of which society is composed. Originally, the domestic was a much more powerful and comprehensive form of association than it is now. In the primitive clan or tribe there are many features which suggest the F. relation. In Greece and Rome we find a close association of servants with the blood-relations. The inner life of the Roman F. deserves a few words. The powers of the head of a F. were three—*potestas*, *manus*, and *mancipium*. The first was either *potestas dominica* over slaves, or *potestas patria* over children; these two were different. *Manus* or marital power placed the wife on the footing of *filiafamilias*. The father had a legal power of selling (*mancipare*) his children into bondage; a *mancipium* was a *filiusfamilias* sold as a bondsman to another *paterfamilias*, to whom he stood in the position of a slave, though otherwise a free citizen, the exercise of political functions being probably suspended. The original power of the father was indeed that of life and death. But this disappeared long before Hadrian and Constantine (A.D. 319) included killing by a father under the crime of parricide. Trajan compelled a father to emancipate a son he had treated with inhumanity. The primitive option of a parent to nurture or to expose was also taken away, and is formally prohibited by a law of Valentinian (A.D. 374). In the same way a law of Diocletian and Maximian declares the sale, donation, and pledging of children to be un-

lawful. The surrender of a child to satisfy a claim of damages based on the child's wrong-doing lingered in the law, but even this was prohibited by Justinian. But in extreme poverty parents might sell children at birthtime (*sanguinolenti*). In polygamous countries a different set of conditions is presented, in which the influence of father and mother is entirely separate; while in Transylvania, Servia, and other Slavic countries in the S.E. of Europe, households of fifty and sixty are still found presided over by the house-father.

Family, a division of the animal and plant world used in classification. The F. is a group which embraces a number of more or less nearly-allied genera (see GENUS). Thus, the F. *Felidæ* (q. v.), forming one of the subdivisions of the great Carnivorous order of *Mammalia*, includes the principal genus *Felis* and allied genera, represented by such nearly-related animals as the lions, tigers, cats, lynxes, &c. The F. in turn forms one of the subdivisions of the higher 'order.' In some cases, where the animals to be classified are not numerous, the F. may be omitted altogether, the genera in such a case being directly included in the Order (q. v.).

Family of Love, a religious sect founded about the middle of the 16th c. by Henry Nicholas, a Münster Anabaptist, who, after making several converts in Holland, crossed to England, where his doctrines won considerable favour among the ignorant. He held himself to be greater than Moses or Christ, for while Moses preached hope, and Christ faith, he preached love. He made religion identical with love, independent of dogma; through love men could be absorbed in God, and even things forbidden were enjoyable by the pure. These teachings resulted in coarse license, and in 1580 Queen Elizabeth caused the sect to be scattered and their books burned. In 1604 they sought permission from James I. to answer the attacks made on them, and tried to ingratiate themselves with the king by slandering the Puritans, but their request was refused, and the sect gradually died out through the frequent exposure of their sensual practices. See Roger's *Displaying of an Horrible Secte of Grosse and Wicked Heretiques naming themselves the F. of L.* (Lond. 1579); Mosheim's *Ecclesiastical History*, ch. xvi.; and Collier's *Ecclesiastical History of England.*

Fan ('that which *blows*;' Old Eng. *fann*; *cf.* Ger. *wanne*, Fr. *van*, from Lat. *vannus*: the Fr. *éventail* is from *éventer*, 'to raise a wind'), an ornamental object used principally by ladies to cool their faces by agitating the air. The modern European F. usually consists of a decorated mount attached to a stick, composed of two master-pieces and slender radiating ribs, in such a manner that the fan may be folded or spread out at pleasure. The mount may be formed either of silk, paper, vellum, lace, or other thin and light material; and the stick, of ivory, bone, mother-of-pearl, wood, tortoiseshell, &c. The F. had its origin in the East, and among the civilised nations of antiquity it was regarded as an emblem of majesty and power. Rigid feather-plume fans with long handles were used by both sexes among the Greeks and Romans; and from the painted pottery preserved from remote ages we know that the opulent had servants to wave fans over them, as is customary in Oriental countries at the present time. The F. in one form or other is now common to all countries. Prior to the 15th c. the folding F. was unknown in Europe; but even then it had long been in use among the Japanese and Chinese, the latter people having adopted it from their more skilful and ingenious neighbours. From China it was brought to Europe by the Portuguese; and in the 16th c. it was common to Portugal, Spain, Italy, and France. In the time of Henry VIII. English ladies generally carried a feather F. suspended to the girdle, and till after the period of the Restoration folding fans were scarcely known in England. Some early English fans were provided with very long handles, so long, indeed, that ladies walked with them. They seem to have served to chastise the unruly and disobedient. In Beaumont and Fletcher's *Wit at Several Weapons*, occurs

'Wer't not better
Your head were broken with the handle of a fan?'

and in 1 *Henry IV.* ii. 3, Hotspur says, 'I could brain him with his lady's fan.' One of the most exquisitely humorous of Addison's papers in the *Spectator* deals with the manipulation of the F. The Chinese fabricate cheap folding fans with palm-leaf or with painted silk or paper mounts for export. Fans of inferior quality are made at Vienna, London, and in parts of France and Belgium. In Spain a F. may be bought for a farthing; at a bull-fight exhibition every person buys one. Paris has no rival in the production of the highly artistic F. The *éventailliste*, or F.-maker, commands the services of eminent artists for designs, and only employs the most skilful workmen to carry them into effect. F.-making attained great excellence in the reign of Louis XIV., and many of the fans then produced were so costly that they were simply expanded for ostentation and not for utility. Fans belonging to the epoch of *le Grand Monarque* are much prized and eagerly sought after for private collections. The language of the F., in which most ladies of last century were deeply read, has now almost died out. In Spanish-speaking countries, however, the F. is still an instrument of diplomacy and intrigue, and by it a coquette can convey to her admirer her train of thought.

A special form of instrument for producing currents of air, used in certain industrial operations, is designated a F. See FANNERS.

Fanar'iots, a name given at first to the inhabitants of the Fanar or Greek quarter of Constantinople, so called from its beacon (Gr. *phanarion*). These Greeks, after the capture of Constantinople by the Turks, made themselves, by their adroitness and business talents, very useful as secretaries to Turkish ministers and dignitaries. Towards the close of the 17th c. all the dragomans were chosen solely from their ranks, and this greatly swelling their influence, they induced the Porte to choose the hospodars or governors of Wallachia and Moldavia from them exclusively. These hospodars were followed to their provinces by hosts of F., who held various offices, and wrung wealth from the provincials by the most unprincipled rapacity. The F. no longer exist as a distinct class. See Zallony's *Essai sur les F.* (Mars. 1824; 2d ed. 1830); and Finlay's *History of the Greek Revolution* (Edinb. 1861).

Fan'cy. See IMAGINATION.

Fandan'go, a lively Spanish national dance, in triple time, executed to the accompaniment of the guitar, the dancers beating time with castanets.

Fan'euil Hall, in Boston, Massachusetts, was built and given to the town by Peter Faneuil in 1742. It was frequently used for public assemblies during the War of Independence, and was hence known as 'the cradle of liberty.' It is still used as a public hall, and has several good paintings.

Fan'fare, a French term denoting a flourish of trumpets or other brass instruments. The music is of Moorish origin, and passed from Spain to France and other countries. A derivative from F. is *fanfaron*, meaning a braggart, probably from the noise he makes, while his braggadocia is called *fanfaronnade*.

Fanfish, or **Sailfish**, the name given to the *Histiophorus immaculatus*, a species of Teleostean fishes belonging to the family *Xiphiidæ* or swordfishes. The name is derived from the great height and size of the dorsal fin, which the fish appears to raise or depress at will. The ventral fins are very small, and the tail is deeply forked, its lobes being of equal size. The F. inhabits tropical seas, and is common round the coasts of Ceylon.

Fang (Old Eng. *fang*, 'that which *takes* or *seizes*,' from *fon*, a contraction of *fangan*, 'to seize;' *cf.* Ger. *fangen*, Dutch, *vangen*, Dan. *fange*). A thief captured while carrying stolen goods is, in Scottish legal phraseology, 'taken with the F.' As a noun it still survives in standard English, as in the 'fang' of a wild beast; while in Scotland people still speak of a well having lost its 'fang.' It was used as a verb by the Elizabethans; thus Webster says, 'He's in the law's clutches; you see he's *fanged*.'

Fann'ers, a deriv. from Fan (q. v.), a form of blowing apparatus used in agriculture for winnowing the chaff from the grain of corn. It consists essentially of a revolving fan with four or five arms or vanes, mounted within a box or case. The fan draws in air through openings at the side of the case, and throwing it forcibly forward against the mixed grain and chaff fed into the apparatus, drives the light chaff out at an opening at the opposite end of the case, the grain falling down and being delivered by spouts at the sides. The heavier and plumper grains fall nearest the fan, while lighter grains are carried further on, and may be delivered by a separate spout. It is thus possible

to separate the grain fed into the hopper into three or four qualities, besides freeing it from the chaff. F. constitutes an essential part of a thrashing-machine, and farmers usually are supplied with a separate barn-F. The finishing F., or duster, is a simpler apparatus used for re-winnowing grain, or, as its name indicates, for dusting or cleaning grain which may have lain any time in the granary. The F. was invented by Andrew Cavers, a farmer in Roxburghshire, in the early part of the 18th c. The principle of the F. is adopted in many important metallurgical operations for creating a powerful blast of air.

Fa'no, an Italian watering-place in the province of Urbino e Pesaro, 30 miles N.W. of Ancona by railway. It stands a mile N. of the mouth of the Metauro, in a fertile plain, and is well built and girt with walls. It has a cathedral and thirteen churches, in which there are many fine paintings, frescoes, and marbles, among others Guido's 'Annunciation,' and several works by Guercino and Domenichino. The principal manufacture is of silk. The commerce has greatly declined, and the port has been largely silted up. Pop. 19,606. The chief classic relic is an arch of white marble raised in honour of Augustus. F. is the anc. *Fanum Fortunæ*, so called from the temple to Fortune built here by the Romans after the battle of the Metaurus.

Fan-Palm, a popular name (suggested by the form of the leaves or fronds) given to various species of Palms (q. v.) belonging to the genera *Mauritia, Hyphæna, Livistonia*, &c. The F.-P. of Europe (*Chamærops humilis*) and the palmetto of N. America are examples.

Fan'shawe, Sir Richard, a diplomatist and poet, was born at Warrenpark, Hertfordshire, in 1608. He studied at Cambridge, entered the Inner Temple, and was sent to Madrid by Charles I. in 1635 as secretary to the embassy. F. espoused the royal cause in the civil war, was taken prisoner at Worcester (1651), and on being freed, joined Charles II. at Breda. He was sent after the Restoration as ambassador to Madrid, where he died, 16th June 1666. F. translated Guarini's *Pastor Fido* (1647), Camoens' *Lusiad* (1655), Horace's *Odes*, and the fourth book of the *Æneid*. He wrote also original verse, *A Short Discourse on the Long Wars of Rome*, and a Latin version of Fletcher's *Faithful Shepherdess*. He was an elegant and spirited translator. His letters were published in 1701.

Fans, The, a race on the equatorial coast of W. Africa, chiefly on the Gaboon river, of a copper-brown colour and slight build. They have revolting cannibal practices, and are said to barter their dead with each other. They wear dresses of bark, stain themselves with red wood, and hold wild orgies at every full moon. Their traditions assert that they came from the N.E., and they seem to be the 'Yagas' of the old Portuguese writers. See Schweinfurth's *Heart of Africa* (Lond. 1873).

Fan'tail, the name given to several species of Insessorial birds belonging to the section *Dentirostres* of that order, and to the family of the *Muscicapidæ* or fly-catchers. Certain varieties of Pigeons (q. v.) are so called from the spreading nature of the tail-feathers. The *Rhipidura albiscapa* of Australia, popularly known as the white-shafted fantail, is a well-known species. The bill in this genus has long basal bristles, the nostrils being partly hidden by plumes; the first wing-quills are short, the fourth and fifth being longest. The tail is broad, and the tarsi are broadly scaled. The colour of the species just mentioned is a dusky olive-black on the upper parts, a white streak existing above and below the eye. The throat, edges of the wing-coverts, tips and shafts of the tail-feathers (excepting the two middle feathers) are white; and the tail-feathers when expanded form a fan-like structure. The average length of the bird is about five inches.

Fanta'sia, in music a composition in free form, like the Capriccio (q. v.). In modern music the F. is often an enlargement and embellishment of some popular air; or of melodies from an opera, arranged for performance as an instrumental solo.

Fan'ti or **Fantee**, a country of W. Africa, on the Guinea coast, lies between the rivers Sakuru on the E., and Kaku on the W., and is separated from Ashanti on the N. by dense forests. It is a rich strip of coast-land, yielding much gold-dust, and supporting a numerous people. The Fantis are closely allied in race to the Ashantis, who conquered them and greatly destroyed their country in 1807. See Captains Brackenbury and Wilson, *Fanti and Ashanti* (1874).

Fan-Tracery, a beautiful form of vaulting, invented by English architects in the 15th c. It is used in Late Perpendicular work, and is found only in England. The ribs which compose it spring from the capitals of the shafts with a uniform outward curve, and the spaces between these diverging ribs are filled by a rich tracery of foils and cusps. Fine examples of F.-T. are to be seen at Peterborough; King's College, Cambridge; Ely; St George's Chapel, Windsor; Henry VII.'s Chapel at Westminster; and in the cloisters at Gloucester. F.-T. was often used over tombs, in cloisters, chantry chapels, and other small buildings.

Fan-Vault of Chapel of Henry VII., Westminster.

Far'aday, Michael, D.C.L., F.R.S., an illustrious English physicist, was born at Stoke-Newington, London, September 22, 1791. The son of poor parents, he received the most elementary education, and was apprenticed in 1805 to a bookbinder. Here he used well his opportunities for acquiring knowledge; and his reading, together with evening lectures by a Mr. Tatum, which he sometimes attended, gave his mind a strong bent towards physical and especially electrical subjects. While working as a journeyman bookbinder, he obtained the patronage of Sir Humphrey Davy, and became his assistant at the Royal Institution in 1813. He subsequently travelled with Davy on the Continent, and soon after his return in 1815, made his first published contribution to science, an analysis of some caustic lime from Tuscany. In 1820 his attention was directed to Œrsted's discovery of the action of a current upon a magnet, and his *History of the Progress of Electro-Magnetism* (1821) prepared him for his later celebrated researches in this and allied branches of physics. In 1823 he liquified chlorine, and in 1824 was elected a Fellow of the Royal Society. Of his chemical papers which appeared in the *Philosophical Transactions* about this time, that relating to the discovery of benzol deserves special notice. He succeeded Davy as lecturer at the Royal Institution in 1827, and was appointed Professor of Chemistry there in 1833. In 1831 he returned to his electrical researches, and made his great discovery of magneto-electric induction—the generation of electric currents in conductors moving relatively to a magnet or other current. This led to a series of investigations to establish the 'identity of electricities,' and later, in 1833, to the hitherto but little understood subject of electrolysis, his papers on which evince at once his high experimental skill and his profound mental acumen. From 1836 to 1838 frictional electricity engaged his attention, the outcome of his researches being the discovery of the specific inductive capacity of insulators or *dielectrics*, a discovery of the highest importance in submarine telegraphy. In 1841 he established the 'magnetisation of light,' or the rotation which a plane polarised ray of light undergoes in a magnetic field. Then followed his researches in diamagnetism, and his investigations on the magnetism of gases and atmospheric magnetism. In 1835, at the suggestion of Lord Melbourne, he received from Government a pension of £500, and in 1858 the Queen allotted him

a residence in Hampton Court, where he died, August 25, 1867. F. was a man of simple and unaffected tastes, of open and unassuming character, and of deep personal piety. In physical science he is unquestionably the greatest experimentalist that England, perhaps the world, has ever seen. His principal works are *Experimental Researches on Electricity* (3 vols. 1839, 1844, 1855), *Lectures on Various Forces of Matter* (3d ed. 1862), and *Lectures on the Chemical History of a Candle* (2d ed. 1866). See *Life of F.* by Tyndall (1869), and by Bence Jones (2 vols. 1870).

Farai'zi, a name derived from the Arabic *farz*, 'a command,' and applied in India, and especially in Bengal, to the reformed sect of Mohammedans who are generally known as Wahabs. About the year 1827, a pilgrim from Mecca, on returning to his native village in the district of Furreedpore near Dacca, taught the new faith to his neighbours. It is supposed that the majority of the Mussulmans in Eastern Bengal, who there outnumber the Hindus, now belong to the F. sect. In 1831 the propagandism gave rise to serious riots, and again in 1870 the villagers of the Gangetic delta were found to be carrying on intrigues with the armed rebels on the frontier of the Punjaub; but at the present time there is no reason to doubt the loyalty of this portion of the Indian community.

Farce (from the Ital. *farsa*, Lat. *farcire*, 'to stuff,' or from the Provençal *farsum*, 'a ragout or mixture,' like the Lat. *satura*), a form of the drama which seeks to provoke mirth by dialogue and incident more ludicrous and less natural and refined than is admissible in comedy. The Greek *satyric plays* were essentially farces. *Saturæ*, or farces combining conversation with music and dancing, and *fabulæ Atellanæ*, or farces of Campanian origin, were the most popular of the Roman dramatic entertainments, and, even under the Cæsars, gave publicity to political feeling in their ribald, vigorous dialogue. In the middle ages, *jeux*, or profane dramatic performances, were common, and from these arose the farces of the *clercs de la Basoche*—a society founded in Paris in 1303. (See BASOCHES.) These early French farces were short, seldom exceeding 500 lines, mostly indecent, and without the stinging wit of the *fabliaux*. Coarse and frequently impromptu farces prevailed on the French stage until Molière founded genuine French comedy. In Italy the term *farsa* was applied to comic plays, which seem to have been modified from the ancient *fabulæ*, and which were greatly developed at the end of the 14th c. by Sannagarro. In mediæval Germany *farce* denoted a song chanted during divine service. In England farces appear distinct from comedy about the beginning of the 18th c. Perhaps the most notable name in English farcical literature is that of Samuel Foote (q. v.).

Far'cy, a disease of horses, closely associated with Glanders (q. v.), and distinguished by the inflammation and swelling of the lymphatic or absorbent vessels of either or both hind-limbs. The inflammatory process extends to the formation of ulcers, and of swellings known as 'F.-buds.' The treatment for the local affection is cauterisation with the hot iron; but constitutional remedies—such as the internal administration of copper and iodine—with good feeding and dry bedding, are also demanded. The poison producing these diseases is capable of being transmitted from the horse to the human subject, from one human being to another, and also to the horse and ass. It may be absorbed both by the cutaneous and mucous tissues, and thus infect the blood. The attention of the profession was first called to this disease in man by Mr. Muscroft in the *Edinburgh Medical and Surgical Journal* (1821).

Fardel-Bound, an old veterinary term for obstruction of the third stomach—the 'manyplies'—of cattle, generally caused by tough or indigestible food, such as leaves, moist clover, or grass, and the like. The results of this affection are inflammation of the stomach, together with paralysis from its distension. The bowels are constipated and the skin is hot, and feverish symptoms also prevail, whilst rumination is necessarily interfered with. The remedies to be adopted for the relief of this complaint consist in free purgation and injections; probably the latter are safest in the generality of cases. The food must be light, and consist chiefly of soft mashes. The stimulants needed in severe cases may consist of ale with ginger.

Fare'ham ('the dwelling at the ferry'), a market-town of Hampshire, England, on F. Creek, at the N.W. angle of Portsmouth Harbour, 5 miles N.N.W. of Spithead by railway, with manufactures of bricks, leather, and pottery. Vessels of good tonnage come close to F., which has an active trade. Pop. (1871) 7023.

Far'el, Guillaume, 'the pioneer of the Reformation in Switzerland and France,' was born at the hamlet of Farels, near Gap, Dauphiny, in 1489. His parents, who were Romanists, destined him for the army; but in 1500 he betook himself to Paris University, where he became a devoted disciple of Lefèvre d'Étaples, and gained a chair in the college of Cardinal de la Moine. Lefèvre's advanced views calling down the wrath of the Sorbonne, he and F. had to quit Paris for Meaux, then a stronghold of Lutheranism, where F. began to denounce the Catholic Church. In 1524 F. sustained at Basel thirteen theses on the chief points of controversy between the Catholics and Reformers, and about this time won the friendship of Haller and Zwingli. Thenceforth he gave himself up to the conversion of Switzerland, making the canton Bern the centre of his missionary labours, preaching with tireless and fervid zeal, and running great dangers from his rash and uncompromising iconoclasm. After the issuing of the Edict of the Reformation by the municipality of Geneva in 1535, F. laboured along with Calvin to organise there the new Protestant Church, a difficult task from the excesses of the *Libertins*, or Reformers who refused to obey any authorities in matters of religion. After allaying (1542) the disorders rife among the Protestants of Neufchâtel, and preaching at Metz, Montigny, and Gorge—where he was nearly killed in a skirmish—F. was sent in 1557 with Beza to seek the intervention of the German Reformed princes in behalf of the Vaudois, and after his return to Switzerland married a young girl, much to Calvin's displeasure. In 1561 he was imprisoned at Gap, but escaped by a basket lowered from the ramparts. Shortly after making a last visit to Calvin, who was then dying, F. ended his days at Neufchâtel, September 13, 1564. F. was not a systematic theologian, nor even a judicious ecclesiastic, but he was an admirable preacher, fluent, impressive, ardent, and as a missionary was the chief agent in the conversion of Switzerland. Among his numerous works, which, however, give no idea of his mastery of language, are *Themata Quædam Latine et Germanice Proposita* (1528), *De Oratione Dominica* (1524), and many epistles and treatises, many of which are inserted in Ruchat's *Hist. de la Réforme en Suisse*. See Kirchhofer's *Leben Wilhelm Farel's* (Zurich, 1831); Schmidt's *Études sur F.* (Strasb. 1834); Goguel's *Vie de F.* (1841); *F. und Viret* (Elberf. 1860); and MM. Haag's *La France Protestante* (Par. 1847–59).

Farewell, Cape, the southern extremity of Greenland, is dangerous to navigators from the masses of ice in its neighbourhood, which are constantly being forced by currents setting in from the N.E. round into Davis' Straits.

Fari'a Y Sousa, Manoel, a Portuguese critic, poet, and historian, was born 18th March 1590. His father's name was Amador Perez de Erro, but when, after a successful university career, he entered upon diplomatic life, he took the name of his mother. From 1631 till within a few years of his death, which took place June 3, 1649, he held the post of secretary to the Spanish embassy at Rome. F. is best known for his poems, consisting chiefly of eclogues, madrigals, and sonnets, written both in Portuguese and in Spanish; his treatises on poetry, which caused Lope de Vega to style him the first critic of the age, and of which his great commentary on the *Lusiad* (Mad. 1639) is the best; and his historical works, treating of Portugal and its dependencies. His *Imperio de China*, edited by Father Semmedo, and translated into French and Italian, is still recognised as one of the best of the elder authorities on the subject.—**Manoel Severim de F.**, a Portuguese historian and antiquary, born at Lisbon 1581, died at Evora, 16th September 1655. He wrote *Noticias de Portugal* (Evor. 1624; 3d ed. Lisb. 1791), and was reckoned one of the best numismatists of his age.

Fari'na, a name frequently applied to the flour or the starch of cereals or of other starchy plants, such as the cassava, arrowroot, &c. It is derived from the Latin *far*, meaning spelt wheat. In commercial circles the term F. is restricted to the starch obtained from potatoes, which is very extensively consumed as an adulterant of the more expensive starches, such as arrowroot, tapioca, &c., and of butter and other articles of food. It is also prepared as an article of food under the name of French sago, and it is largely employed as the basis of starch sugar,

which, under the name of saccharine, is much used by brewers. Its chief consumption, however, is as a thickener in calico-printing, for which it is also prepared by torrefaction as dextrin or British gum. Fossil F. is an infusorial earth, the *berg-mehl* of the Swedes and Laplanders.

Farina Trit'ici, the grain of wheat, *Triticum vulgare*, ground and sifted, is used in medicine for the preparation of *Cataplasma fermenti*. When made into a paste with honey, it forms an excellent application for boils.

Fari'ni, Car'lo Lui'gi, an Italian politician and author, was born at Russi in the Romagna, October 22, 1812. He studied medicine at Bologna, and became known as a writer of scientific treatises, but being connected with the Liberal movement of 1841–43, had to quit the Papal territory, and resided successively at Marseille, Paris, Florence, and Turin. On Pius IX. granting an amnesty, F. established himself as a physician at Osimo, but shortly afterwards, entering on a political career, became under-secretary of state, and was sent in 1848 on a confidential mission to the camp of Carlo Alberto. He held aloof from the Roman Republic of 1849, and his services being rejected by the Church party after the French occupied Rome, he betook himself to Piedmont, where his moderate but liberal views secured him the royal favour. He was made minister of public education, knighted, elected to the Piedmontese National Assembly, and in 1859 named dictator of the duchy of Modena. He rendered important services in uniting central Italy to Piedmont, was appointed minister of state and royal secretary, refused in 1862 to join the Ratazzi ministry, became president of the cabinet, retired in 1863, and died at Genoa, August 1, 1866. He wrote *Storia dello Stato Romano dal Anno* 1814 *al* 1850, a valuable historic work, which has gone through several editions; *Storia d'Italia*, a continuation of Botta's history of Italy; and letters to Gladstone, &c. F. was one of the most sagacious of Italian statesmen, and Italy is greatly indebted to him for her present stable government.

Farm (Old. Eng. *feorm* and *feorme*, originally 'food;' next, the 'rent' (paid in kind) of land; finally, the 'rented land' itself), a portion of land or tract of country occupied as one undertaking for the cultivation of crops, or for the rearing and maintaining of cattle, sheep, and other creatures useful to man. Farming, viewed in its widest sense, is the greatest, as it is the primal and fundamental, industry of the human race. On its operations, to a great extent, depend not only the feeding, but the clothing of mankind, and most of the plants which are cultivated, and of the animals said to be domesticated, are so as a result of farming operations. Taking a narrower and technical view of farming, it embraces only those lands on which cereal, pasture, and green crops are cultivated, and sheep and cattle reared. Gardening and the cultivation of many products of human industry are embraced under other heads.

In Great Britain farms are classed under two heads—(1) arable farms, and (2) natural pasture and hill farms. Arable farms again are subdivided into (1) ordinary arable or grain-producing farms, (2) stock farms, and (3) dairy farms. These subdivisions are not sharply distinguished from each other, and they merely indicate the prevailing feature in the agricultural industry of any special locality or F., such features being generally controlled by circumstances of soil, situation, and climate. Thus on a F. in the great wheat-producing districts, a certain proportion of stock is fattened, and dairy produce is prepared, although its staple may be grain. The stock F. is principally devoted to the rearing and fattening of cattle for the fat market, and crops and field operations are all directed with a view to that chief object. In the case of a dairy F. the ultimate object of the farmer is the obtaining of milk for sale or for the manufacture of butter and cheese, and stock is selected and crops grown suitably for such objects. Natural pastures and uncultivated hill land are extensively laid out as sheep farms or sheep walks; and a F. of this description usually embraces a great area.

The size of farms is entirely regulated by convenience; but there is an increasing tendency to form farms of great extent. The scientific development of agricultural operations, and the introduction of expensive, yet economical, labour-saving appliances, render it necessary for a first-class F. to be one of considerable size, that it may yield a sufficient return for the capital sunk in appliances connected with its working. A great revolution in rural affairs has therefore taken place within recent times; the cottier and small farmer have disappeared, and small holdings have been combined to form large farms, which must be worked by persons having command of considerable capital. The modern farmer must also be possessed of a wide range of scientific and practical knowledge, of considerable mechanical skill, and much business aptitude. Concerning the laws which regulate the occupancy of land, see LAND LAWS, LANDLORD AND TENANT, and HYPOTHEC.

Farm Buildings. The various offices and structures required for the working of a farm are collectively known in England as the homestead, and in Scotland they are called the steading. The accommodation necessary varies in size and arrangement, according to the extent of the farm it serves, and the nature of the chief products cultivated. Thus on a dairy farm the cow byre and dairy offices are the chief feature, and on a stock farm prominence must be given to the feeding byres and arrangements for preparing food. As the health of his live-stock is an object of supreme importance to the farmer, F. B. ought to be placed in situations securing, as far as possible, abundant water supply, good drainage, freedom from damp, and a sheltered yet airy situation. The arrangement of F. B. is a matter of much practical importance, and the various parts should be so compacted that operations dependent on each other, or following in consecutive order, should be performed in immediate proximity; and the saving of all unnecessary labour, as well as the prompt and rapid execution of work, ought always to be kept prominently in view. The position of the thrashing mill and barn will generally be found to be the key to the arrangement of the whole range of F. B., as many of the most laborious duties of a farm, such as the feeding and littering of the live-stock are intimately connected with that department. It is usually found that F. B. of moderate extent come together most conveniently in the form of three sides of a square or parallelogram. The space lying between the projecting sides is either roofed over or left as an open court, and used as a yard for young cattle during the winter (if unroofed, with a covered shed attached), and as a repository for the manure from the stables and byres at its side. The ordinary F. B. comprise a thrashing-mill, granary and straw-barn, stables, stock and dairy byres, court and covered sheds for young cattle, calves' house, piggery, poultry house, sheds for storing turnips, boiler and food-preparing house, implement house, and cart-shed. The dairy is usually attached to the farmhouse, at once as a matter of convenience, and because that department must, as far as possible, be removed from all noxious smells. The farmer's house and labourers' cottages also form an essential part of F. B., but the arrangement and size of these are regulated by the principles of ordinary domestic architecture.

Farm Servants. The wages of F. S. is in Scotland a privileged debt. See WAGES.

Far'mer, Richard, D.D., an English scholar and archæologist, was born at Leicester, August 28, 1735. Educated at Emmanuel College, Cambridge, where he graduated in 1760, he was first appointed curate of Swavesey, near Cambridge, became Master of Emmanuel in 1775, and librarian to the university, and was successively canon of Lichfield, Canterbury, and St. Paul's. He died 8th September 1797. The following year his library, especially rich in works of Old English literature, was sold for £2210. F. collected copious materials for the history of Leicester, which he put into the hands of his friend Nichols. His sole work is his *Essay on the Learning of Shakespeare* (1776), reprinted by Steevens (1793), by Reed (1803), and by Harris (1812). In this he showed that Shakespeare's knowledge of the ancients was obtained from translations.

Farmers-General (Fr. *fermiers-généraux*) were persons who, under the *ancien régime* in France, obtained, for a fixed money payment, the right to collect one or more of the public taxes. This was the most expensive and least productive system of collection. Such rights, originally given to court favourites, were first exposed to public auction by Sully. After Colbert had detected the frauds of the individual collectors, a company or *ferme-générale* was formed in 1728, which, interrupted for a short time under the administration of Silhouette in 1759, continued in business till Necker's time, when it consisted of forty-four persons paying a rent of 186 millions of livres, and making an estimated profit of only two millions. The multiform and

arbitrary nature of French taxation, and the quasi-official and yet practically irresponsible position of the F.-G. and their agents, led to great oppression. The French 'imposts' consisted in the first place in the '*taille roturière*,' at first a purely feudal contribution, but which the king, pressed by the expense of a standing army, gradually extended to the domains of his nobles. From 1,500,000 livres, in 1445, it rose under Henri IV. to fourteen millions, under Louis XIV. to thirty-five millions, under Louis XVI. to ninety-one millions. The *taillon* and the *crue* were additions to the *taille*. In 1710 Louis XIV. imposed a *dixième* on the revenues of the lands of nobles and churchmen, as well as of *roturiers*. Another *vingtième* was added for the war of American independence. In 1695 appeared the *capitation*, which affected the *roturier* class, the nobles, and public officers unequally, but from which the clergy were exempt. The *dîme*, estimated by Necker at 133 millions, went to the Church, but relieved the state of obligations towards the Church. Every five years the Church gave the king the *don gratuit*, about 3,600,000 livres. The *corvée* was a tax of eight days' labour, with cart and horse, on the public roads; its value was twenty millions. *Maîtrise* and *jurande* were taxes upon trade corporations and professions, which in 1788 produced 4,500,000 livres; and *vingtième d'industrie et de commerce* was a special tax on manufactured products and merchandise. The latter, along with all products whatever, were subject to the indirect tax or *aides*, which included *droits de sortie* or *traite foraine*; the tax on the extraction and sale of salt, which from 1345 was called *gabelle*; and certain dues on the sale of food, and the entry of wine into towns. As Charles VII. had dispensed with the consent of the States-General in imposing the *taille*, so François I. dispensed with their consent to the *aides* and *gabelle*. Certain of the *aides*, amounting in value to fifty-nine millions, were collected by the *régie générale des aides*, and were called *droits réunis*. The *ferme-générale* extended to the *gabelle*, which alone amounted to seventy-four millions, of which fifty-four reached the treasury; the monopoly introduced by Colbert for tobacco; the *droit d'entrée* on imported goods, originally one-thirtieth, imposed in 1581; the customs proper, internal and external. There was a third system of succession duties and feudal exactions, which were collected by the *régie des domaines*. The eighty *pays d'élection* formed twenty-four *généralités* for the purposes of collection, the gross amount being divided among the *généralités* by a *brevet général*, but the further division among towns and parishes was at the pleasure of the *intendant*, and among different lands and persons by no fixed system of valuation. The *pays d'états* (such as Languedoc, Provence, Burgundy, Artois) had a much juster system, worked by *livres cadastrals*, or valued rent, and called *affouagement* (or 'hearth-tax'). In the *pays d'élection*, also, Necker's system of collection was to give three or five or six '*deniers pour livre*' to the various grades of officers, while the *pays d'état* put the collections up to auction in each province. The former were also called *pays de grande gabelle*, from the rate of salt-tax they paid; the latter, *petite gabelle*, or *franches* or *redimés*. The authorities on this important subject are Necker's *Administration des Finances*, Clamagéran's *Histoire de l'Impôt*, Laferrière's *Histoire du Droit Français*.

Farne or **Fern Isles**, or the **Stapes**, a group of small islands from 2 to 5 miles off the coast of Northumberland, and S.E. of Lindisfarne. Several are merely rocks hidden at high water. On one is a priory named after St. Cuthbert (q. v.), who spent the last two years of his life here. They render navigation very dangerous. There are two beacons 30 feet high on two of the islets. Here Grace Darling (q. v.) effected the heroic rescue of nine people from the wreck of the *Forfarshire* in 1838.

Farne'se, the name of a noble Roman family, dating from the 13th c., but first made important by **Alessandro F.**, who in 1534 became Pope Paul III.—His natural son, **Pietro Luigi**, who figures in the Life of Benvenuto Cellini, was about the worst man of his time. He got from his father the duchy of Castro as a fief of the Holy See, and Novara, an imperial fief, and the dukedom of Parma and Piacenza, subject to a payment of 8000 ducats to the pope. This division of papal property among popes' children was often practised. The new *gonfaloniere*, after a life of vice and tyranny, was murdered 10th September 1547 by Gonzaga, the governor of Milan, and others.—His son, **Ottavio** (born in 1520), recovered from Philip II. possession of Piacenza, which had been occupied by Milanese troops. His friendship for Henri II. of France was suspected by the emperor and the pope, and he owed much of his security to his wife Margaret, governor of the Low Countries, the natural daughter of Charles V. He died in 1587.—**Alessandro**, son of Ottavio, known as *the* Duke of Parma, became one of the great captains of the age. He was with Don John of Austria at Lepanto (1571), and in 1578 defeated the Flemish 'Beggars' at Gembloux. Wonderful stories are told of his *sang-froid*, or rather love of danger, at the sieges in the Low Countries—Oudenarde, Antwerp, &c. As governor of the Spanish Netherlands he fought long and bitterly with the Prince of Orange. Philip II. gave him the command of the force gathered at Dunkirk for the invasion of England in 1588, and in 1590 sent him to the relief of Paris, besieged by Henri of Navarre. Ill supported by the Catholic League, he was forced to yield to the superior force of the Huguenot prince, and died 3d December 1592, at Arras, of a wound received before Rouen.—His son, **Ranuzio I.** (born 1569, died 1622), lived on the worst terms with the other Italian princes, especially Gonzaga of Mantua. He built the beautiful theatre of Parma.—His son, **Odoardo** (born 28th April 1612, died 12th September 1646), having pledged the duchy of Castro in the *Mont de Piété*, formed an alliance with France in 1633, which protected him against Pope Urban VIII., wishing to forfeit Castro for the Barberini, his relatives. Muratori describes Odoardo as a brilliant and satirical talker, and of a splendid fashion of living.—**Ranuzio II.**, son of Odoardo, was born in 1630, and succeeded his father in 1646. He was ruled by a Provençal tutor and a Pavian tailor of a musical turn. In consequence, he lost the duchy of Castro to Innocent X. He died 11th December 1694, and was succeeded by his son **Francesco**, who was born 19th May 1678. During the reign of the latter occurred the Treaty of the Hague, by which it was agreed that Parma and Piacenza should become male fiefs of the empire; and that, when the succession opened, they should go to the eldest son of Elizabeth F., Queen of Spain, daughter of Odoardo, and his male issue, whom failing, to her other sons and their male issue. The undoubted legal claim of Innocent XIII. to the reversion of the duchies was coolly set aside. Francesco died 26th February 1727, and was succeeded by his brother **Antonio**. In him the hereditary corpulence of the family reached its utmost extent. He died 20th January 1731, and having no children, left the duchies by will to Don Carlos, the son of his aunt, Elizabeth of Spain. The name has been given to two palaces in Rome—one built by Pope Paul III., and adorned with some fine works of art; the other, known as the *Farnesina*, containing frescoes by Raphael—to a group of statuary representing 'Dirce Bound to the Horns of a Bull,' and to a Hercules copied by Glykon from an original by Lysippus.

Farn'ham ('the dwelling among the ferns'), a town in Surrey, England, on the Wey, 36 miles S.W. of London, with an interesting old castle, which has more than once been rebuilt or enlarged, and is a possession of the bishops of Winchester. The chief trade is in hops. William Cobbett was a native of F. Pop. (1871) 4461. At a distance of 6 miles lies the camp of Aldershot.

Farn'worth, a town of Lancashire, 12 miles S.E. of Liverpool, and a station on the Manchester and Bolton Railway. It has a chapel of the 15th c., a free grammar-school, and manufactures of watches, canvas, and iron tools. Pop. (1871) 9226.

Fa'ro (Gr. *pharos*, 'a lighthouse'), the chief town of the province of Algarve in the S. of Portugal, at the mouth of the Fermoso, 122 miles S.S.E. of Lisbon. It is a bishop's see, is well built, walled, and has a college, cathedral, and several hospitals. The harbour is small but safe, sheltered by islands, and defended by a fort. F. has a large fishery. The trade in fresh and dried fruit, wine, anchovies, sumach, and cork is carried on chiefly with England. Pop. 7900.

Faröe Isles (Dan. *Faareyjar*, 'sheep islands'), a group of twenty-two basaltic islands in the N. Atlantic, 185 miles N.W. of the Shetlands, in lat. 61° 20'-62° 20' N., and long. 6°-8° W. Area, 504 sq. miles; pop. 9992. They are conical mountainous masses, some 2000 feet high, rising more or less abruptly from the sea, and are separated from each other by strong rapid currents. The precipitous shores, rendered dangerous by whirlpools, are broken by many deep inlets, which form secure havens. Stromö, the chief of the group, contains the capital,

Thorshavn (pop. 900), and is 8 miles broad and 27 long. Eight of the group are uninhabited islets. The shallow soil of all the islands affords rich pasture for the sheep and cattle, but there are no trees larger than a juniper or stunted willow. Although often visited by tempests, the climate of the F. I. is comparatively mild, allowing the cultivation of barley, rape, and potatoes. The snow only lies on the ground for about eight days in winter. There are 583 species of plants, of which 270 are flower-bearing. A seam of good Miocene coal was recently discovered on Sydeiö. The seas abound with fish, and the rocky coasts are haunted by myriads of seafowl, the capture of which is one of the perilous industries of the islanders. Among the exports, which are chiefly to Denmark, are salted mutton, skins, tallow, eider-down, goose-quills, and feathers. The F. I. were discovered and peopled by Norwegians in the 9th c., but have been Danish since 1380. A dialect of Old Norse is still spoken, but Danish is used in the churches, schools, courts, &c. The islands send a representative to the Danish *Rigsdag.* See R. Chambers's *Tracings of Iceland and the F. I.*

Far'quhar, George, son of a poor clergyman, was born at Londonderry in 1678. He studied at Trinity College, Dublin; at eighteen joined the stage, and shortly afterwards the Earl of Orrery's regiment in Ireland. Like Wycherley and Vanbrugh, he became a captain. His first comedy, *Love and a Bottle*, was brought out successfully at London in 1698. Duped into marrying a pretended heiress, he fell into poverty, and died in April 1707, 'leaving nothing,' he said, 'but two helpless girls.' His other plays are *The Constant Couple, Sir Harry Wildair, The Inconstant* (modelled on Fletcher's *Wild Goose Chase*), *The Stage-Coach, The Twin Rivals* (1705), *The Recruiting Officer* (1706), and his best piece *The Beaux Stratagem* (1707). F.'s plays are not imaginative and romantic. They are sprightly, natural transcripts of the life of his times. He will not rank with even the secondary Elizabethans, but his place is high among the Restoration dramatists. Inferior to Congreve in dazzling wit, he excels him in humour and invention. His plays are less gross, his characters more genial and lovable, than Wycherley's, Congreve's, or Vanbrugh's. The best edition of F. is Leigh Hunt's in Routledge's *Old Dramatists* (1875). See Hazlitt's *Comic Writers* and Ward's *English Dramatic Literature*, vol. ii.

Farr, William, M.D., F.R.S., D.C.L., was born at Kenley, Shropshire, in 1807, studied at the universities of Paris and London, practised medicine at London, and edited the *Medical Annual* and *British Annals of Medicine*. He was made compiler of abstracts in the Registrar-General's office in 1838, is now head of the statistical department in that office, and has been sent by Government to various international statistical congresses. He was made corresponding member of the French Institute in 1872. F. has written a number of articles for medical journals, and many statistical papers and reports.

Farr'agut, David Glasgow, a gallant and highly popular admiral of the American navy, was born near Knoxville, Tennessee, July 5, 1801. He entered the navy at the age of eleven, was lieutenant at twenty-one, and in 1833 commanded the *Natchez* on the Brazil station. In 1851 he was made assistant-inspector of ordnance, and in 1854 was appointed to construct a navy-yard in California. In January 1862 he commanded a naval expedition to the Gulf of Mexico, and on the 28th of April received the surrender of New Orleans. Ascending the Mississippi, he took Natchez, but failed before Vicksburg. Withdrawing to Pensacola, he was made Vice-Admiral of the Navy, and in March 1863 he sailed up the Mississippi, ran the Confederate batteries of Fort Hudson, and aided General Grant in his attack upon Vicksburg, which surrendered July 4, 1863. In August 1864, after a fierce conflict between his fleet and the Confederate forts and vessels of Mobile, he captured the forts and city. F. was raised to the rank of admiral in 1866. He died August 14, 1870.

Farr'ar, The Rev. Frederic William, M.D., F.R.S., son of a clergyman, was born at Bombay in 1831, and studied at Trinity College, Cambridge, of which he was made a Fellow in 1856. He was appointed assistant-master at Harrow in 1855, master of Marlborough School in 1869, and chaplain in ordinary to the Queen in 1873. F. has been a prolific author. Among his works are *Eric, or Little by Little*, and *Julian Home*, successful tales; *The Fall of Man* (1865); and *The Life of Christ* (1874). He edited *Essays on a Liberal Education* (1868).

Farr'ier (Old Fr. *ferrier*, from Lat. *ferrum*, 'iron'), a name given to the early representatives of the veterinary surgeon, who to their ordinary occupations as blacksmiths and horse-shoers added that of prescribing for the ailments of domestic animals. In many country districts the F. is still extant. It is needless to remark that his ideas on veterinary matters are marked by much prejudice and ignorance, not, however, unmingled with the rough and ready knowledge obtained by observation.

Farriers, Army, the name given to non-commissioned officers in cavalry regiments who assist the veterinary regimental surgeons, and act as horse-shoers. They rank with and receive the pay of sergeants, and have certain allowances arising out of their occupation.

Fars or **Fars'istan** ('Fars' is the native form of the classic *Pers*-ia), a province in the S. of Persia, bounded W. by Khuzistan, N. by Irak, E. by Kirman and Suristan, and S. by the Persian Gulf. Area, 55,000 sq. miles; pop. about 1,700,000. F. comprises the Dashtistan, a sandy, thinly-peopled plain fringing the Persian Gulf, and an upland district, formed by offshoots from the Yagros range, which rise in steep terraces, and are severed by long fertile plains abounding in rich pasture. Around Shiraz there are delightful woody valleys almost destitute of inhabitants, but the F. consists of arid sandy tracts. The chief rivers are the Band Amir or Araxes, the Nabon, and the upper waters of the Tab. F. contains the salt lakes of Bakhtigan and Dariacht. The chief products are fruit, opium, tobacco, sulphur, and lead; cutlery, arms, glasswork, cotton cloths, and wine are manufactured. The principal towns are Jahrum, Daralgird, Fasa, Firozabad, Kazinrum, and Shiraz. F. is famous for its antiquities, of which the most famous are the ruins of Persepolis, Pasargadæ, and Shapoor.

Farsan' Archipelago, a group of islands in the S.E. of the Red Sea. Only two are of any extent—F. Kebeer, 31 miles long, and F. Seggeer, 18 miles.

Far'thing (Old Eng. *feorthung* and *feorthling*, 'the fourth part of anything'), now denotes a copper coin, the fourth part of a penny. The term is sometimes applied to articles or circumstances of contemptible value, *e.g.*, a farthing rushlight.

Far'thingale (in 16th c. *verdingale*; from Fr. *verdugalle*, or *vertugale*, a corruption of *vertu-garde*, 'guard of modesty'), a large hooped petticoat worn in the 16th c. See CRINOLINE.

Fa'sa, a town in the province of Fars, Persia, 77 miles E.S.E. of Shiraz. It has manufactures of silk, wool, and cotton. The pop. has been estimated at 18,000. The *district* of F. is 45 miles long by 9 to 15 broad, and is generally known as the *Garm Sar*, or 'warm region.' It produces rice, Indian-corn, millet, cotton, and fine tobacco, and contains thirty-three villages.

Fasa'no, a town of S. Italy, in the province of Bari, on the highroad from Bari to Brindisi, near the coast, and 33 miles S.E. of Bari. It is famous for its olive plantations. Pop. 11,450. On the coast, near F., is the ruined *Egnazia.*

Fas'ces (from the same root as the English 'bind') were a bundle of birch (sometimes elm) rods, with an axe stuck in the midst, the iron of which projected from them. They were carried by officers called lictors before the superior magistrates of regal, republican, and imperial Rome, as a sign of their power of scourging and of capital punishment. When an inferior met a superior magistrate, he ordered his lictors to lower their F., as a mark of respect; and, in the same manner, the consuls at the public assemblies acknowledged the sovereignty of the people.

Fas'cia. These are strong membranes formed of connective tissue which cover the muscles, send septæ or partitions in between them so as to give them support, and in many cases give points of origin to muscular fibres. They are smooth, glistening, and opalescent in appearance to the naked eye. When a portion is teased out and examined under the microscope, they are found to be composed of delicate fibres of connective or white fibrous tissue firmly matted together.

Fascicula'ria, a well-known genus of *Polyzoa* (q. v.) (formerly known as *Meandropora*), and found in a fossil state in rocks of Tertiary age. This genus (of which *F. cerebriformis* of the Miocene rocks is a familiar species) presents a singular structure from the cœnœcium or connecting medium of the

Polyzoon being more or less spherical in form, and composed of vertical plates arranged not unlike the convolutions of the human brain.

Fascina'tion by Serpents. See SERPENTS, FASCINATION BY.

Fascines' (Lat. *fascis*, 'a bundle of twigs'), bundles of brushwood, generally about 9 inches in diameter, and from 6 to 12 feet long, used in war to fill up a ditch, &c. In civil engineering F. are used to protect the banks of rivers, &c.

Fasci'ola, the name of the genus of *Trematoda* (*Scolecida*) to which the Flukes (q. v.) belong. *F. hepaticum* is the scientific name for the common liver fluke, formerly known as *Distoma hepaticum*.

Fasciola'ria, a genus of Gasteropodous mollusca represented by the tulip whelk (*F. tulipa*) and allied species. These shells belong to the family of the *Muricidæ* or Whelks (q. v.).

Fash'ion (Fr. *façon*, 'a mode,' from the Lat. *facio*, 'I make'), literally a particular manner of making anything, is a term applied to a prevalent mode of dressing, speaking, and acting, and even to literary styles and to opinions current in society. F. may thus be an index of deep changes, a result of peculiar social conditions, or the passing reflection of the idlest whim. Thus the broad contrast between the flowing richly-coloured robes of the East and the dress of Europeans is due to differences of climate and manners of life, while the constant variations of dress in Europe arise mainly from caprice. F. in dress seems to have fluctuated far less in ancient than in modern times. In classic Greece there was comparatively slight variety in costume, and in the arrangement of the filleted or unfettered hair. Plautus, however, tells us that the Roman matrons often altered the materials and shape of their garments. In England there have been several broadly marked fashions of dress. The early English settlers in Britain wore ringed armour and square helmets in war, woollen tunics, short cloaks, and drawers in peace. Their hair was long, and they practised tattooing, though it was forbidden by an edict in 785 until the Norman conquest. The Normans introduced brighter and more costly dresses. Short mantles and long tunics, of brilliant silks and velvets, lined with furs, flowered with gold, and often stiff with jewels, were worn by the nobles, and peaked-toed shoes (*ocreæ rostratæ*) were common. The most minute and faithful picture of English mediæval fashions is to be found in Chaucer's Prologue to the *Canterbury Tales*. In the 16th c. French fashions spread into England, Germany, and Italy. In England during Elizabeth's reign the costume of the wealthy was remarkable for splendid colour and lavish and often fantastic ornament. Men wore slashed doublets of silk, velvet, or damask, jewelled and embroidered with gold and silver, trunk-hose of grotesque width, and cloaks, sometimes short, sometimes trailing on the ground, of red, white, violet, black, green, &c. The female apparel was specially marked by the high linen ruff, and huge Farthingale (q. v.). The reign of Charles I. is the age when English costume was most becoming and picturesque. Van Dyck's portraits have made us familiar with the cavalier dress—the crimson doublet or gold-worked buff coat, the broad plumed Flemish hat, the rich lace collar, the long fringed breeches, the cloak, baldric, and Spanish rapier The female dress became very graceful, the ruff and farthingale being disused. In Charles II.'s time the King Charles costume was spoiled by extravagant additions, such as petticoat breeches and perukes. The dress of the ladies lost its tasteful simplicity, as is seen by comparing Lely's with Van Dyck's paintings. The 18th c. in England was the age of the Louis XIV. dress, the age of powdered wigs, blue or scarlet coats, embroidered waistcoats, knee-buckles, and high-heeled shoes. In this century it was at one time the F. to carry the hat under the arm instead of on the head, to place black patches on the face, and to stiffen the coat-skirts with wire. Fans, canes, and snuff-boxes were incessantly manipulated, a F. which evoked the raillery of Addison and Pope. After the French Revolution more sober costumes were adopted. F. in dress has at times gone to such excess as to call forth royal interference. Thus in England about the middle of the 16th c. there was such a mania for square-toed shoes, that an edict was passed forbidding any one to wear shoes above six inches broad at the toes. Queen Elizabeth, we are told, placed 'certain grave citizens' at the London gates to cut all ruffs above a 'nayle of a yeard' deep, and to break all rapiers above a yard long. Charles V. of France forbade the wearing of short and tight breeches, which had become a public scandal. There are fashions in literature as well as in dress and social etiquette. After the Renaissance it was the F. to write Ciceronian prose; Euphuism (q. v.) was a literary F. for a time prevalent in England; during one age the sonnet, during another the epic, has been the favourite form of poetry, each successful author inducing others to imitate his theme and manner by the example of his success and influence of his authority. Anagrams, *bouts-rimés*, and similar follies arose from a literary F. now happily decayed. See Planché's *British Costume*, La Bruyère (*Sur les Mœurs*), and Hazlitt's essay on F.

Fash'oda (formerly *Denab*), the most southerly Egyptian town and fort on the Upper Nile, lies in the Shilluk country, 380 miles S. of Khartum, in lat. 10° N. It is the seat of a mudir, and has a garrison of some 300 men. On account of the poll-tax all boats are compelled to stop at F. for several days. The town has arisen since 1869.

Fastern's, Fasten, or **Fasting Even**, an old Scotch and English name for Shrove Tuesday (q. v.).

Fasti (Lat. *fas*, 'divine law,' or *fari*, 'to speak;' hence *dies fasti* are *lawful days*, *i.e.*, on which business might lawfully be transacted before the prætor, or days on which judgment could be pronounced—court days) were arranged by the Romans in two divisions:—1. *Fasti sacri* or *kalendares*. These were tables closely resembling a modern almanac, and contained the lore with respect to the days of the year, &c., which for nearly four centuries and a half after the foundation of Rome was retained by the priests, but was then disclosed by Cn. Flavius, who had obtained access to the pontifical books. They contained the months and days of the year, with the nones, ides, market-days, lawful days, unlawful days, the different festivals, &c.; astronomical observations on the rising and setting of the fixed stars, and the commencement of the seasons; and notices of great victories, dedications of temples, &c. Specimens of these F. on stone and marble have been discovered from time to time, the most remarkable being that known as the *Kalendarium Prænestinum*, laid bare in 1770. The F. is the title of a well-known poem of Ovid, which treats of the festivals, &c., according to the order of the Julian Calendar. 2. *Fasti annales* or *historici*. From the resemblance in arrangement of the early historical records to the *F. Kalendares*, the name F. was extended to the registers of consuls, dictators, censors, &c., and generally to the chronicles of the events of each year. The *F. Capitolini*, excavated from the Forum in 1547, arranged by Cardinal Alessandro Farnese, and deposited in the Capitol, are regarded as a most important specimen of this class.

Fast'ing ('fast,' Old. Eng. *fæst*, means lit. a 'keeping' away from food, and is the same word as the adj. fast = 'firm,' as in hold-*fast*, stead-*fast*) is a practice based upon the instincts of human nature, and common to all religions. As the effect of deep sorrow is to take away all desire for food, F. has always been regarded as a natural expression of sorrow for sin; and as a formal religious practice the object of it would be to afflict and humble the soul by withholding from the body its ordinary nourishment. 'Afflicting the soul' is the phrase used for it in the Bible (Lev. xvi. 29, 31), evidently as a familiar shortened expression for the fuller phrase of Ps. xxxv. 13, lxix. 10. Having, like asceticism generally, its original home in Asia, it was much practised by the ancient Hindus, Chinese, and Persians, and to a less extent by the Jews; it entered into the religious rites of the Egyptians, Greeks, and Romans, and descended to the Christian Church.

I. *Among the Jews.*—The only fast enjoined upon the Jews as a nation by the law of Moses was on the great day of atonement. Whosoever failed to keep that day with F. was to be cut off from among his people (Lev. xxiii. 29). But there are numerous instances recorded of individuals voluntarily imposing fasts upon themselves in seasons of penitential sorrow, as David (2 Sam. xii. 16), and Ahab (1 Kings xxi. 27); and the vow of Num. xxx. probably referred chiefly to F. A number of other individual cases recorded, as Hannah (1 Sam. i. 7), Jonathan (1 Sam. xx. 34), David (2 Sam. i. 12, iii. 35), had no special connection with religion, but were prompted by sheer grief. Even national fasts were imposed on special occasions, as when the Israelites were defeated by the rebel Benjamites (Judges xx.

26), at Mizpah on the restoration of the ark (1 Sam. vii. 6), under Ahab (1 Kings xxi. 12), and under Jehoshaphat (2 Chron. xx. 3). After the Temple was destroyed, and the people carried into captivity and prevented from worshipping God by means of sacrifices, they attempted to make up for this by an increased observance of fasts, as expressed in a prayer in the Talmud—'Lord of the universe! thou knowest that when the Temple existed, the man that sinned brought a sacrifice, and though only the fat and blood were offered, yet he was forgiven. Now that I fast, and my own fat and blood are consumed, let it please thee to accept this sacrifice . . . as if offered upon thine altar, and be merciful unto me.' The following fasts took their rise during the post-exilian period, and are observed by the Jews to the present day for the reasons assigned. 1. Annual national fasts: 1st, the fast held on the 17th of Tamuz, the fourth month, because on this day (1) the Golden Calf was made, (2) Moses broke the Tables of the Law (Exod. xxiv., *cf.* xxxii.), (3) the daily sacrifices ceased for want of cattle when the city was besieged, and (4) Jerusalem was stormed by Nebuchadnezzar (Zech. viii. 19; Jer. lii. 6). 2d, The fast held on the 9th of Ab, the fifth month, because on this day (1) God decreed that those who left Egypt should not enter Canaan (Num. xiv. 27–35), (2) the first Temple was destroyed by Nebuchadnezzar, and the second by Titus, (3) the city of Bethar was taken by Adrian, and 580,000 Jews massacred, and (4) the site of Jerusalem was ploughed up, as predicted by Micah (Jer. xxvi. 18; Zech. vii. 3, 5, viii. 19). 3d, The fast held on the 3d of Tishri, the seventh month, because on that day Gedaliah and other Jews were murdered at Mizpah (2 Kings xxv. 25; Jer. xli. 1–7; Zech. vii. 5, viii. 19). 4th, The fast held on the 10th of Tebeth, the tenth month, because on that day Nebuchadnezzar began the siege of Jerusalem (2 Kings xxv. 1; Zech. viii. 19). 5th, The fast of Esther, held on the 13th of Adar, the twelfth month (Esther iv. 16, 17, ix. 31). 6th, The first-born sons' fast, held on the day before the Passover (Exod. xii.). 2. Weekly fasts were kept every Monday and Thursday between the Feast of the Passover and that of Tabernacles, and between that which followed (Lev. xxiii. 36; Num. xxix. 35–37) and the Feast of the Dedication, because Moses went up to Mount Sinai to receive the second Tables of the Law on a Thursday and came down on a Monday, *cf.* Luke xviii. 12.

II. *In the Christian Church.*—Although our Lord condemned the Jewish manner of keeping their fasts (Matt. vi. 16), and did not impose F. regularly on his disciples (Matt. ix. 14), he yet speaks of it along with prayer as a source of spiritual strength (Matt. xvii. 21), indicates that it would be beneficial to his disciples after his removal from them (Matt. ix. 15), and even practised it himself on a memorable occasion (Matt. iv.). It was practised and recommended by the apostles (Acts xiii. 3, xiv. 23; 1 Cor. vii. 5). From a very early time F. was a part of the discipline of the catechumens, preparing them for baptism, and it soon came to be regarded as also necessary before partaking of the Eucharist. This could not be, so long as the latter was connected with the Agapæ (q. v.), but in the 4th c. Basil, Chrysostom, &c., insisted on the guilt of giving the Holy Communion to persons not F. The bi-weekly Jewish fasts described above were soon received into the Church, Monday and Thursday, however, being changed to Wednesday and Friday in commemoration of the betrayal and sufferings of Christ. These fasts, which were observed every week except between Easter and Pentecost, did not last all day, but only till three o'clock, and hence were called *stations*, as if watches of the soldiers of Christ, and *half-fasts*. By the 3d c. fasts came to be much practised as a safeguard against demons. But while the number of them increased, laxity in the observance of them also increased; for whereas at first F. meant entire abstinence from food, by the 4th c. many thought it sufficient to abstain from flesh and wine, which afterwards came to be the general understanding in the Western Church. The first four of the Jewish post-exilian fasts enumerated above were also introduced into the Church, according to tradition by Callistus, Bishop of Rome, about 223. To un-Judaise them they were connected with the four seasons (Lat. *jejunia quatuor temporum*, corrupted into Ember Fasts), being fixed by the Council of Mainz in the time of Karl the Great to the first week in March, the second week in June, the third week in September, and the week immediately preceding Christmas Day. More sacred than all the rest was the fast preceding Easter (see LENT), although up to the 4th c. it was left optional, and the exact length of it was not finally fixed till the 6th c., or, according to some, the 8th c. About the middle of the 5th c. a new fast was instituted in France and soon adopted elsewhere, under the name of the Litany or Rogation Days (q. v.), being the three days before Ascension Day. Besides these, and the Vigils (q. v.) or eves of holy-days, there were many other fasts having merely a local or partial observance. From the 6th c. F. began to be imposed as a mode of penance. In the *Penitentiary* of Theodore, Archbishop of Canterbury (668), three fasts of forty days each—before Easter, before the Nativity, and after Pentecost—are appointed to be held every year as special seasons of confession and penance. The fasts appointed to be observed by the Book of Common Prayer of the Anglican Church are Lent, the Ember days, the Rogation days, all Fridays except Christmas Day, and the vigils before certain festivals. See Blunt's *Dictionary of Doctrinal and Historical Theology* (1872); Smith's *Dictionary of Christian Antiquities* (1875); Bingham's *Ecclesiastical Antiquities.*

Fat is a tissue found in many parts of the body, and is composed of a meshwork of fine connective tissue, in which lie embedded cells called *F. cells.* These are round or oval if lying apart, but if they happen to be packed closely together, they may acquire an angular form. Their average size is from $\frac{1}{300}$ inch to $\frac{1}{600}$ inch in diameter. Each consists of a delicate transparent envelope of an albuminous substance, surrounding a single drop of fluid fatty matter. Young F. cells have a nucleus, but this becomes obscured, and may entirely disappear in old F. cells. Fatty tissue is sometimes termed adipose tissue. It is copiously supplied with blood-vessels.

Chemical Composition.—The F. of the human body is a mixture of margarin and olein, which are in turn formed of a base, glycerine, combined with the respective fatty acids, margaric and stearic acids. The F. of oxen and sheep contains, in addition, another substance called stearin. During life it is in the liquid state, but it solidifies after death.

Uses of Fat.—(1) It serves as a soft, elastic, and light packing for the various vacuities which are in the body. (2) It facilitates motion by diffusing pressure, and it also protects delicate organs from pressure. (3) It gives a smoothness to the contour of the body, specially observable in the graceful lines of the human female. (4) Being a bad conductor of heat, it prevents heat from escaping from the body, and thus assists in maintaining the equable temperature of the body. (5) Consisting largely of carbon and hydrogen, by its combustion in the lungs or in the tissues, it is a great source of animal heat, being converted, by union of its elements with oxygen, into carbonic acid and water. (6) It assists largely in the general nutrition of the body, almost every tissue containing more or less of this substance.

Source of Fat.—F. is derived in the body from three sources—(1) from F. introduced as such in the food; (2) from hydrocarbons, such as starch and sugar, which are converted into F.; and (3) from a special kind of retrograde metamorphosis, or splitting up of the albuminous tissues.

Fa'talism (from *fatum*, what is spoken and therefore irrevocable) is, according to Leibnitz, of three kinds. There is the F. of Mahomet, which supposes that if the effect were predetermined it happened without the cause—*Kismet*, 'it is fated;' 'ye cannot will, unless the Lord willeth.' Next comes the F. of the Stoics, which taught men to be quiescent, for they were powerless to resist the course of things. There is a third F. held by Christians, which admits a certain destiny of things regulated by the providence of God. 1. Pure F., based on the Greek idea *eimarmenē*, 'what is allotted,' or *moira*, 'the awarded lot' (which is perhaps seen in the Homeric *aisa, aei ousa*), or on the Chaldæan idea of astrological fate, undoubtedly means that our actions do not depend on our desires or volitions, and that a higher power bends us to its will, against which it is vain to struggle (*ineluctabile fatum*). The reasoning of the Turk under impending calamity is (or was)—'If this is fated to happen, I cannot prevent it; if not to happen, why should I exert myself.' 2. The description of Leibnitz is unfair to the Stoics. Chrysippus undoubtedly held that the human will is always determined by motives, but he did not even maintain the modified form of F. according to which our character is made *for* us, and not *by* us, so that we should in vain attempt to alter it, and are therefore not responsible for our actions. There is in this, of course, a portion of truth, viz., the law of heredity, which has frequently given a powerful interest to psychological romance, and which is occasionally illustrated in actual life. But the position of the Stoics

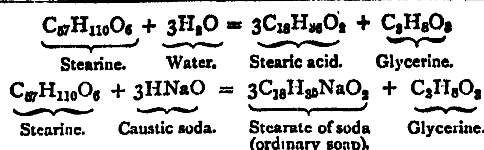
was practically the reverse of this. They laid stress on a man's power to transform and discipline his own mind, controlling or suppressing some emotions, generating others, forming new intellectual associations. They recognised the unchangeable laws of life, and endeavoured to bring the character into harmony with the Kosmos. It was the man of ill-regulated life who came into conflict with the overruling force—*Ducunt volentem fata, nolentem trahunt.* 3. It is an interesting question whether Christians are fatalists to any extent. The verdict of psychology is simple enough; the normal healthy human character is amenable to moral discipline, and we can improve it if we desire. But apparently the volitions tending to improve character are theoretically as capable of prediction as others. This view is entirely consistent with the Christian doctrine of the foreknowledge of God, and with the predestination of the body of Christ. Nevertheless the Church has frequently condemned views of individual predestination. Many theologians contend that while free-will was lost by the fall, the bondage of the will to sin does not preclude absolute individual responsibility; although it is also maintained that nothing can be done without grace. But whatever may be said of Christian theology, it cannot be doubted that the preaching of the Christian religion has been one of the greatest anti-fatalistic influences in the world.

Fata Morga'na, the name of a sorceress in the Romance poetry of Italy, who showed her magic power by raising up visionary spectacles in the air; hence the name given in Italy to a mirage seen in the Strait of Messina—images of men, ships, houses, &c., showing themselves both in the air and the water.

Fates. See PARCÆ.

Fa'ther. See PARENT AND CHILD, FAMILY, and PATRIA POTESTAS.

Father Lasher (*Cottus bubalis*), a species of Teleostean fishes, belonging to the Gurnard family (*Triglidæ*), and to the sub-family *Cottinæ* or Bullheads (q. v.). In this genus the head is very broad and flat. No scales exist. The dorsal fins are of moderate size, and no palatine teeth are developed. The F. L. has its head armed with long sharp spines. It is common on our coasts, and is frequently found amongst rocks and tangle at low water. Its average length is 10 inches; its upper parts are brown coloured, and its under parts white. Both are marbled with darker colours, and the fins especially are so marked. The F. L. is also known by the names 'long-spined cottus' and 'lucky proach.'



Fathers, Christian, or **Fathers of the Church,** is a title given to the ancient Christian writers who belonged to the communion of the Church. The name of *Apostolic Fathers* (q. v.) is given to those of the 1st c. who, according to tradition, were disciples of the apostles. Various limits of time down to which the name ought to be applied have been adopted—any time from the 3d c. to the 7th c. A common division is to make the Patristic period end with the 6th c., and the Hierarchical begin with the 7th c. In its widest application the period extends to and includes St. Bernard in the 12th c., after which theologians receive the name of Scholastics. Not less various have been the estimates formed of the importance and value of their writings. As a rule, that estimate has been higher in the Roman Catholic Church than in the Protestant Churches. This is connected with the Roman Catholic doctrine regarding the Rule of Faith (q. v.), in which Tradition—at once the *interpreter* and the *supplement* of Scripture—plays so important a part. As the same authority is held to be due to the former as to the latter, it follows that the writings of the F., in which this tradition is chiefly contained, are inspired and infallible as well as Scripture. At the same time several Roman Catholic writers, when they started with the theory that doctrines were to be settled not by individuals, but by councils or the Church, have pointed out with remarkable candour the defects of the F. Protestants, who hold the Holy Scriptures to be the only infallible rule of faith and practice, in seeking to refute the Roman Catholic doctrine regarding tradition, went to the opposite extreme in their treatment of the F.: in seeking to drag to the light all the errors and faults of their writings, they naturally overlooked all that was valuable in them. Thus, although Daillé in his *De Vero Usu Patrum* (1631), the first thorough Protestant work that appeared on the subject, did not fail to point out their merits, the opinion generally adopted, at least by Calvinistic Protestants, was as one-sided as that of the Roman Catholics; and the prejudice against the F. which has been handed down among them, until quite recent times, as unreasonable as the adoration of the Church of Rome, for it was deemed right to despise, ridicule, and reject the whole body of their writings. It has been otherwise in the Church of England, which in her Church polity did not go so far as the Calvinistic Churches in opposition to Romanism, and in her doctrine did not so closely follow Augustine, who differed widely from the other F. She has always entertained great reverence for them, and the exaltation of them was a marked characteristic of the Tractarian revival.

Looked at without prejudice, the F. appear to be neither without great faults nor great excellences. Judged by the standards of the present day, they were very deficient. They were superstitious and credulous in a high degree. Only a few could be called learned, and as a body they were ill qualified to be interpreters of Scripture, being ignorant of the original languages, and too fond of allegorising. On the other hand, they were laborious and diligent, devotedly attached to the religion they professed, and zealous and courageous beyond all praise in its defence. To judge them fairly, they must be viewed in the light of their own time; and taken for neither more nor less than what they are, their writings are of incalculable value for tracing the development of doctrine and practice in the early Church. Among the more famous of the F. may be mentioned (1st c.) Clemens Romanus, Polycarp, Papias; (2d c.) Justin Martyr, Irenæus, Clemens Alexandrinus, Tertullian; (3d c.) Origen, Hippolytus, Cyprian; (4th c.) Eusebius Pamphili, Athanasius, Basil, Chrysostom, Gregory Nazianzen, Ephraem Syrus, Hilary, Lactantius, Ambrose, Jerome, Augustine; (5th c.) Cyril of Alexandria, Theodoret, Theodore of Mopsuestia, Pope Leo I., Orosius; (6th c.) Procopius, Gregory the Great, Gregory of Tours, Gildas, Isidore, all of whom receive separate treatment. See Donaldson's *Christian Literature and Doctrine* (Lond. 1864); Davidson's *Sacred Hermeneutics* (Edinb. 1843); Mosheim's *Church History* (Reid's ed.).

Fath'om (Old Eng. *faethm*; comp. Dutch *vadem*, Ger. *fadem*; perhaps connected with Lat. *spatium*, 'a space'), a measure of length in nautical surveying and in mining, 2 yards or 6 feet, *i.e.*, about the distance between the finger-tips of a man of average size when his arms are extended horizontally. It is also used metaphorically to express the reach of a man's capacity, 'I cannot fathom it' being equivalent to 'I cannot comprehend it.'

Fat'imides, or **Fat'imites,** a dynasty of califs who ruled Egypt and the N. of Africa from the 10th to the end of the 12th c. They were so called from their founder, Obeidallah Almahdi, declaring that he was descended from Fatima, daughter of Mohammed, and wife of Ali, an assertion which most Arab historians disbelieve. Obeidallah, with the help of the Berbers, dethroned the last of the Aglabites, who governed at Tunis, and made himself ruler of N. Africa from the Atlantic to the borders of Egypt. Moez, the fourth calif, subdued Egypt and founded Cairo. His fleets defeated the Spaniards, and his armies conquered Palestine and part of Syria. Hakem, the sixth calif, was a fanatic, who proclaimed himself a god, and is still worshipped by the Druses. He persecuted the Christians with fierce bigotry, and was assassinated in 1021. In the reign of Mostanser, the eighth of the F., the Turks were driven back from Egypt. Mostali, the ninth calif, was defeated by the Crusaders under Godfrey de Bouillon at Ascalon. During the reigns of his successors, the power of the F. dwindled away, until in 1169 the dynasty ended in Aladhed-Sidinallah, the fourteenth of the F., who was dethroned by Saladin, the founder of the Ayubite sultanate. See Mill's *History of Mohammedanism.*

Fats. The F. form an abundant group of compounds occurring both in the animal and vegetable kingdoms. In animals the secretion of fat takes place most abundantly immediately below the skin, and in the neighbourhood of the omentum and kidneys; in vegetables principally in the seed and fruit. All F. contain the elements carbon, hydrogen, and oxygen, united in various proportions. Together with many oils, they are characterised by the action which ensues when they are treated with superheated steam and caustic alkalies. By the first of these agents they are resolved into glycerine and a fatty acid; by the second, into glycerine and a salt of the fatty acid, or *soap.*

$$\underbrace{C_{57}H_{110}O_6}_{\text{Stearine.}} + \underbrace{3H_2O}_{\text{Water.}} = \underbrace{3C_{18}H_{36}O_2}_{\text{Stearic acid.}} + \underbrace{C_3H_8O_3}_{\text{Glycerine.}}$$

$$\underbrace{C_{57}H_{110}O_6}_{\text{Stearine.}} + \underbrace{3HNaO}_{\text{Caustic soda.}} = \underbrace{3C_{18}H_{35}NaO_2}_{\text{Stearate of soda (ordinary soap).}} + \underbrace{C_3H_8O_3}_{\text{Glycerine.}}$$

F. are indeed the ethers of glycerine, and may be formulated generally as $C_3H_5O_3(F)_3$, where F is the radical of the fatty acid. F. are lighter than water, in which liquid they are insoluble. They may be dissolved in ether, bisulphide of carbon, turpentine, &c. They melt when they are heated, their fusing point increasing with the proportion of carbon they contain. When strongly heated they are decomposed into acroleine, various hydrocarbons, &c. The most important of the animal F. is stearine, and of vegetable F. palmitine. They are employed in the manufacture of soap, glycerine, and candles, and in medicine in the preparation of ointments.

Fatt'y Acids. See OILS.

Fatty Degenera'tion is attended by a continually increasing accumulation of fat replacing the minute elements of tissue in different organs, and is essentially a sign of weakness or of death of the part, the elements of the tissues which perish being replaced by fat-granules. F. D. is quite distinct from accumulations of fat which do not replace other elements of tissue. Examples of F. D. may be seen in the minute elements of the muscular tissue, especially of the heart; in the acini of the liver, the blood-vessels, &c. Nearly all cell structures may undergo F. D., except, perhaps, red blood corpuscles, and the elements of nerve tissue. Yellow softening of the brain, however, is described as a form of F. D. *Arcus Senilis* (q. v.) is due to F. D. of the substance of the cornea, and is regarded as symptomatic of similar degeneration in other parts of the body. There is no kind of tissue, healthy or morbid, which may not undergo F. D., and it consequently gives rise to a great variety of local diseases. F. D. of the heart, or of the larger vessels, or of those passing through important organs, such as the brain, generally terminates in sudden death by rupture, followed by syncope.

Fatu'ity. See INSANITY.

Fat'uous, in law. A F. person, or an idiot, is legally incapable (see CAPACITY, LEGAL) of managing his affairs. See IDIOTS AND LUNATICS.

Fau'ces, the Latin name of the throat, or opening between the mouth and the pharynx.

Fau'cher, Léon, a French statesman, was born at Limoges, 8th September 1803, and first emerged into notice after the revolution of 1830, when he began to write for the Liberal opposition papers. He had already given his attention to economics, proposing a southern union to counterbalance the German *Zollverein*, and arguing for common work in prisons, and the separation of town and country convicts for different kinds of work. In 1845 he published his valuable *Études sur l'Angleterre* (chiefly of the industrial centres), which did much to spread free-trade principles in France. In 1846 he entered the Chamber of Deputies, and spoke on the currency and on the reform of the customs' tariff. In the revolution of 1848 he occupied an independent position, criticising the paper-money and other financial proposals of the Provisional Government, arguing against the limitation of the hours of labour, and suggesting that the masses in the national workshops, '*nourris par la patrie*,' being dangerous in Paris, should be sent to work on the railways. As Vice-President of the new Legislative Assembly he strongly opposed the tendency to sentimental, paternal government; he was always the unsparing critic of the Socialist budget. F., who believed in the possibility of a parliamentary government under the presidency of Napoleon, was for six months minister, but retired when the *plébiscite* by universal suffrage was proposed. He died at Marseille, 14th December 1854. See his *Mélanges d'Économie Politique et de Finance* (2 vols. Par. 1856), published by his friend Wolowski.

Fau'cit, Helen, an English actress, born in 1816, made a successful *début* as Julia in the *Hunchback*, at Covent Garden, London, in 1836. She soon rose to the summit of her profession, became a member of Macready's companies at Covent Garden and Drury Lane, and won wide repute for her refined, powerful rendering of Juliet, Beatrice, Imogen, Rosalind, Lady Macbeth, and other Shakespearian characters, and as the heroine in various pieces by Lytton, Browning, and Westland Marston. Her representation of Antigone was a remarkable success, and called forth an eloquent tribute from De Quincey. After her marriage with Theodore Martin, in 1851, this gifted actress continued to appear at intervals on the stage, from which she has now retired.

Fault, in geology, is a fracture, accompanied by a displacement, which breaks the continuity of the strata, altering the relative levels of contiguous portions.

Fault, in law. If the quality of a commodity sold prove inferior to what was represented, the buyer may reject it. Even if the buyer saw the goods, a *latent* F. may entitle him to reject them, and should they perish in consequence of it, he will be relieved from payment, or entitled to recover the price. But if the F. or deficiency of a commodity seen by the buyer is manifest, the rule is *Caveat emptor*, *i.e.*, the risk is the buyer's. Challenge on ground of F. must be without unnecessary delay. See ERROR IN ESSENTIALS.

Faun, or **Faun'us** ('the favourer,' from *faveo*, 'I favour'), in the mythic history of Italy was the third king of the Laurentes, and was noted for his devotion to hunting, cattle-breeding, and agriculture. He came to be worshipped both as a rural and as a prophetic divinity. His festival (the *Faunalia*) was celebrated on the 5th of December. F. was also the dream-god, hence he and his wife, Fauna, were known respectively as *Fatuus* and *Fatua*, the foretellers of destiny. His appearances under the images of fauns, half man, half goat, correspond with the satyrs of Greece; hence F. was identified with the Arcadian Pan after the myths of the Greeks had emigrated into Italy.

Faun'a, the name applied to indicate the entire *animal* population of any given continent, country, or region. The term is used in opposition to that of *flora*, applied to the *plant-life* of any district. The name F. is derived from the Roman fauns or satyrs, who were supposed to protect wild animals.

Fau'riel, Claude, a French scholar and critic, was born at St. Étienne, Loire, 21st October 1772. After acting as private secretary to Fouché from 1799 to 1802, he devoted himself to literature, and became one of the most profound and widely accomplished scholars of modern France. In 1830 he was appointed Professor of Foreign Languages at Paris; and there for fourteen years he delivered most ingenious and learned lectures on comparative philology, the sources of French and Italian, the Spanish drama, Servian poetry, &c. F. died at Paris, 15th July 1844. His great work is his *Histoire de la Gaule Méridionale sous la Domination des Conquérants Germains* (4 vols. Par. 1836). It is a masterpiece of learned research and brilliant art. Another admirable production is *Histoire de la Poésie Provençale* (3 vols. Par. 1846), in which he traces the origin of many of the chivalric ideas of honour, love, and gallantry in ancient poems of the Christians fighting with the Moors, or of the Aquitanians struggling against the Karoling kings. Another part forms a work on Dante and the Italian language (*Dante et les Origines de la Langue et de la Littérature Italiennes* (2 vols. 1854).

Fausse-Braye, a low rampart raised round a fortified place, now disused in fortification.

Fausse-Rivière ('false river'), a lake in Louisiana, U.S. of America, formerly a channel of the Mississippi; hence probably the origin of the name.

Faust. The F. legend, a favourite subject in European literature, arose during the struggles of Christianity with magic. Its main incident, the sale of a human soul to the devil, can be traced to the 6th c. tale of *Theophilus* by Eutychianus, which was translated by Germans and Scandinavians, occurs in Hroswitha and in the *Aurea Legenda*, and was popularised in the 13th c. by Rutebeuf's *Miracle de Théophile*. Hans Sachs has a similar story. In the 16th c. this legend of selling a soul was attached to the name of F. It has been said that the monks connected the tale with F. the printer in revenge for the injuries which his art caused their lucrative trade of book-copying; but the true protagonist of the modern version of the legend seems to have been a Georg or Johann F., perhaps the printer's son, *professor of magic* at Cracow

University early in the 16th c. He was a reputed necromancer, known to Melanchthon, who relates tales of his *diablerie*. The Polish legend of Twardowski, the printer of Cracow, who sold himself to Satan, seems to have grown from a confusion of F. of Cracow with F. the printer. The first version of the old legend, thus associated with the name F., was given in the *Volksbuch* of Spiess (1587), and on it Christopher Marlowe based his *Tragical History of Dr. Faustus*. In the narrative of Spiess and Widmann (1599), Helen of Greece is bestowed by Mephistopheles upon F. in place of a legitimate wife, but Margaret has not appeared. In Scheible's *Das Kloster* (1728) we meet with 'a beautiful but poor girl,' whom F. is prevented by supernatural interference from marrying, and who in succeeding versions gradually rises in importance, and finally becomes the Margaret of Goethe. Attempts have been made to find a common origin for the legend of F. and Don Juan (q. v.), and C. Grabbe, a German dramatist, wrote a play in which both F. and Don Juan appear. The story is still popular in Germany. The most notable poems upon it are Klinger's *F.'s Leben* and Goethe's masterpiece. Lessing wrote a drama on the F. legend, which, with the exception of a fragment, is unfortunately lost. Goethe's *F.*, having been turned into a libretto by Barbier and Carré, received an operatic form from Gounod. The plot of Calderon's *Magico Prodigioso* is similar to the F. legend, as is an old French play, *Mystère du Chevalier qui donna sa Femme au Diable* (1505), and, in a less degree, Byron's *Deformed Transformed*. See Düntzer's *Die Sage von Dr. Johann F.* (Stutt. 1846), and Peter's *Die Literatur der Faustsage* (Leips. 1857).—**Johann F.** or **Fust**, a goldsmith of Mainz, who, along with Gutenberg, Schöffer, and Coster, is accredited with the invention of printing by movable metal types. In 1450 he entered into partnership in the business of printing with Gutenberg (q. v.), whom he sued in 1455 for 2020 florins, which he had lent him—a loan which some maintain to be the only furtherance F. gave the new art. Decision being given against Gutenberg, F. acquired his printing apparatus, and, aided by Schöffer (q. v.), carried on the business prosperously until the sack of Mainz in 1462. F. died of the plague at Paris in 1466. See PRINTING and GUTENBERG.

Fausti'na, Annia Galeria, married Antoninus Pius several years before the death of Hadrian, and when he became emperor, A.D. 138, received the title of Augusta. She died A.D. 141. **Annia F.**, daughter of the preceding, married Marcus Aurelius about A.D. 145, and died 175. Both mother and daughter are noted for their gross infidelity to their husbands, and for the honours which their husbands, faithful to the unfaithful, heaped upon them before and after their decease. Attempts have been recently made to construct a more favourable reading of the character of the wife of Marcus Aurelius.

Fausti'nus I., a negro emperor of Haiti, originally Faustious Soulouque, was born at San Domingo, 1789, served in various humble capacities, rose to the rank of captain in the army, and was eventually elected president of the republic in 1847. He caused a frightful massacre of mulattoes at Port-au-Prince, 16th April 1848, and in the following year proclaimed himself emperor, continuing to reign till forced to abdicate by the revolution of 1859. He died 6th August 1867.

Fava'ra, a town of Sicily, 4 miles E. of Girgenti, and near the left bank of the Hypsas, a tributary of the Acragas. It has some trade in sulphur, olives, and other fruits. Pop. 12,829.

Fav'art, Charles Simon, born in Paris, November 13, 1710, may be called the author of the *opéra comique* of the 18th c. He aroused the jealousy of the French and Italian comedians, and for some time carried on his theatre in the Flemish camp of Marshal Saxe, who repaid him by seducing his wife, a lady who first had the courage to abandon the absurd *bergère de Watteau* dress on the stage, and to begin the reform of costume. The collected works of F. and his wife appeared as the *Théâtre de M. et Madame F.* (10 vols. Par. 1763–72). F., who composed about sixty comediettas of merit, died May 12, 1792. His son was an actor of some merit, and his grandson, **Antoine Pierre Charles F.** (born 1784), was also a dramatic author, a painter, and diplomatist, and with Dumolard issued the *Mémoires et Correspondence* of his grandfather (3 vols. 1809). An adopted daughter of Antoine, **Marie F.** (born in 1833), has become famous as an actress in comedy.

Fa'versham, a seaport of Kent, opposite Sheppey Island, on a stream flowing into the E. Swale, and 47 miles E.S.E. of London by the London, Chatham, and Dover Railway. It consists mainly of four streets, which form a cross, with the market-place in the centre. The trade is principally in coal, timber, corn, hops, and fruit. There are also breweries, brick-works, and large powder-mills. The oyster fisheries, however, are the chief industry. Pop. (1871) 7198. F. is the old English *Fifresham*, where King Æthelstan held a witenagemot in 930.

Favigna'na (anc. *Ægusa*), an island 6 miles off the N.W. coast of Sicily, forming one of the Trapani Islands, the ancient *Ægates*. It is 6 miles long by 2 broad, is well watered, has rich pastures, and produces wool and excellent wine. Its chief town, also called F., has a pop. of 3245.

Fav'osites (Lat. *favus*, 'a honeycomb'), a genus of Sclerodermic Corals (q. v.) found in a fossil state in the Silurian, Devonian, and Carboniferous rocks, but also represented by living species. They belong to the Tabulate division, and the family *Favositidæ* is recognised by having both septa and corallites distinct, with little or no connecting substance or cœnenchyma.

Favospon'gia, a well-known genus of fossil Sponges (q. v.) occurring in the Upper Silurian rocks. This genus belonged to the section *Calcarea*, or that of the calcareous or limy sponges.

Fa'vre, Jules Claude Gabriel, born at Lyon, March 21, 1809, of a mercantile family, came to the Paris bar about the time of the revolution of 1830, and soon made a reputation by his striking appearances in some of the great political trials. He was an extreme Radical, very independent in character, and a powerful and ready, though somewhat bitter, speaker. After the revolution of 1848 he held the office of home secretary, and drafted Ledru Rollin's election despatch to the local officials, which, though not unusual in French politics, was especially offensive in the case of a ministry pledged to the abstract rights of the people. On the President's election he passed into opposition, and spoke in favour of the freedom of the press and against the Roman expedition and the law of deportation. He refused to take the oath required by Napoleon after the *coup d'état*, and resumed his work at the bar. In 1858 he defended the political criminal Orsini, and subsequently entered the *Corps Législatif*, where he always spoke on the extreme Left, supporting the Austrian war of 1859 and condemning the Mexican expedition. At the Paris elections of 1869 he was run close by Rochefort, the editor of *La Lanterne*. In September 1870 F. became Minister of War, and attempted at Ferrières to negotiate an armistice, during which a Constituent Assembly might be elected, but the conditions required by Bismarck were too harsh. He afterwards held the portfolio of Foreign Affairs, but in 1871 withdrew again to the bar, of which he is *bâtonnier*. F. is a member of the French Academy, an honour merited by his classic eloquence. Besides a variety of speeches and pamphlets, F. has published *Rome et la République Française* (1871), and the *Gouvernement de la Défense Nationale* (1875), in which he narrates the events from the armistice to the taking of Paris, and recommends a moderate Conservative republic for France.

Fa'vus (Lat. 'a honeycomb') is a disease of the scalp, but in a few instances it has been observed on other parts of the body. F. is characterised by the presence of crusts of a bright yellow colour, situated under the epidermis, and scarcely rising above the level of the skin, sometimes exactly circular, but often with an outline representing numerous arcs of circles. The crusts are composed of the sporules and mycelia of a vegetable growth of the fungi order. The growth of the crust is eccentric, and spreads rapidly, and is unaccompanied by discharge of any kind. The hair bulbs are destroyed, and the hair falls out in patches, leaving permanently bald spots. F. is a disease of deranged nutrition, and generally occurs in childhood, and chiefly in families where no attention is paid to cleanliness. It is very common amongst the lower classes in France. Treatment:—Improved hygienic conditions, viz., fresh air, exercise, ablution, both local and general, and appropriate diet. The various preparations of iron are the most suitable medicines. The crusts may be removed by soaking the scalp thoroughly with oil in the evening, and washing it in the morning with soap and water.

Fawkes, Guy (properly **Guido**), an English gentleman, born of a Protestant family at York in 1570. At an early age he became a Roman Catholic, and on his return from the Low Countries, where he had served in the Spanish army, he became head of the Gunpowder Plot (q. v.), a conspiracy formed by several fanatical Catholics for blowing up James VI. and the members of the Commons and Lords, on November 5, 1605. F. was seized when about to fire the train, was put to torture, and executed in Palace Yard, Westminster, January 31, 1605-6. It was formerly the custom in English towns to burn his effigy every 5th November.

Fay, András, a Hungarian author, was born at Kohany in the county of Zemplén, May 30, 1786. Educated for the bar, he became an advocate and politician at Pesth, and in 1835 its deputy at the Diet. Feeble health, combined with the fact that although he was a Liberal, the tide of opinion was in advance of him, compelled him to retire from political life, and to devote himself to literature, social and educational improvements, &c. In 1820 appeared his prose Fables (*Mesek*), which from their charms of style and 'smack of the soil' are still very popular in Hungary. During his later years F. wrote two books on female education and the development of Hungary—*Növevelés* (Pesth, 1840), and *Kelet népe nyn goton* (1841)—and a number of tragedies and comedies, while he contributed regularly to scientific and literary periodicals. A collected edition of his works, in 8 vols., was published at Pesth (1843-44). F. died 26th July 1864.

Fayal' (Port. *faya*, 'a beech-tree'), the chief island of the Azores (q. v.). It is extremely fruitful, abounds in myrtles and orange-trees, and exports largely fruit and wine. Pop. about 25,000. Its capital, Horta, has a pop. of 8549.

Fayette'ville, a town of N. Carolina, U.S., on Cape Fear River, 90 miles N.W. of Wilmington, with which it has regular communication by steamer. It lies in the centre of extensive pine forests, yielding much rosin, turpentine, and timber. It has four cotton-mills, a large general trade, an institute, a large school for coloured children, &c. Pop. (1870) 4660.

Fayûm' (from the Coptic *Pi-om*, rendered by Wilkinson 'the cultivated land,' and by Mariette 'the sea'), a division of Middle Egypt, on the W. side of the Nile, about 65 miles S.W. of Cairo, and 30 miles W. of Beni-Suef, on the Nile Valley Railway. It lies in a depression of the Libyan waste, and is only connected with the Nile valley by a single gorge. Area, 750 sq. miles, 100 of which are occupied by the Birket-el-Kerun ('the horned'), the Lake Mœris of the Greeks. In spite of an arid soil, F. is one of the richest parts of Egypt, yielding figs, dates, grapes, apricots, olives, and roses for the perfume factories. Medînet-el-F., the capital, stands on the E. shore of Lake Mœris, and on the site of the ancient Krokodilopolis.

Feal and Div'ot, a rural servitude in Scotland, in virtue of which the proprietor of a dominant tenement has a right to cut or remove turf to make fences or to thatch houses within the dominant lands. The kindred servitude of *fuel* gives a right to cut, winnow, and carry peats from the servient moss or peat-land. These servitudes may be constituted by express grants or by use or possession following on the usual clause of Parts and Pertinents (q. v.). There is an analogous right of common in England, called *common of estovers*. See ESTOVER.

Fealty (Old Fr. *féalté*, from the Lat. *fidelitas*), in English law, is the duty which the tenant of land owes to him from whom he holds it to perform the services of tenure. The word has not now any practical signification.

Feath'er, a beautiful river in a rich gold district of California, rises in the Sierra Nevada, and enters the Sacramento. Steamers ply on it to Yuba city, a distance of 100 miles from San Francisco.

Feather Grass (*Stipa*), a genus of grasses, so named from the great development of the awns, which in many species resemble a feather, as in the common F. G. (*S. pennata*). These grasses occur more abundantly on the Continent than in Britain, and are frequently used in room decorations, the long awns having an elegant and graceful appearance. They are often dyed. The awns are supposed to favour the dispersion of the seed, and its feration in the soil.

Feathers, the name given to the characteristic appendages of the skin of Birds (q. v.). They present the exoskeleton or outer skeleton of birds, just as scales represent that structure in fishes, reptiles, &c. They are formed in little *papillæ*, or rounded processes of the *dermis*, or true skin. The papilla which gives origin to a feather exhibits a deep middle groove on one side, this groove being broadest and deepest at its base, but shallower as it approaches the extremity of the papilla. Other grooves, which may be called *secondary* ones, are given off at right angles from the primary groove. These secondary grooves are closely set, and extend almost wholly round the papilla, but vanish at the side opposite to that on which the median primary groove is situated. Smaller grooves, which may be named *tertiary* grooves, are given off from the secondary ones, and these tertiary grooves lie in a manner parallel to the primary groove. A feather is formed on such a papilla much in the same manner as fluid metal is shaped in a mould. Horny matter secreted by the skin is pushed over the papilla, and naturally becomes thickest where the grooves are deepest. Thus, as the horny matter is pushed outwards, the material deposited in the central and primary groove becomes the *quill* or *shaft*; the matter deposited in the secondary grooves forms the *barbs*, which together compose the *web*; and the horny substance contained in the tertiary grooves forms the little *barbules*, or processes borne on the *barbs*, which bind the latter together to form the *vane* or *web*. These are the parts seen in any ordinary feather. The quill or barrel of the feather is its last-formed portion, and that by means of which it is inserted in the skin of the bird. The lower surface of the shaft exhibits a groove, the shaft itself consisting of a spongy white pith enclosed in a tough membrane. At the lower aspect of the shaft the barbs of the F. are disconnected, and form downy filaments; *down* itself, well seen in the under layer of F., especially in aquatic birds, consisting of a number of barbs, without any central shaft, united by a short quill. A small or miniature feather, often termed the *rachis*, *accessory plume*, or *plumule*, exists at the point where the quill and shaft unite. In some birds the rachis may be as large or larger than the feather itself, and in such birds as the ostriches, emus, and their allies, the barbs of the F. are not united to form a web, but are disconnected and free. It is this peculiarity of structure which gives to the ostrich F. their singular grace. In the cassowaries and other birds, the texture and appearance of the F. become singularly altered, and give to these birds the appearance of being clothed with long black hair.

The F. of birds receive various names, according to their situation. Those attached to the bones of the 'hand' are named *primaries*; the *secondaries* are attached to the fore-arm, and the *tertiaries* to the arm. The F. attached to the shoulder-blade are the *scapularies*. The *bastard wing* or *alula* is the name given to the collection of F. supported by the rudimentary *thumb*. The quills of the wings are covered at their bases by small F. forming the *wing-coverts*, the tail F. or *rectrices* being similarly protected by *tail-coverts*. F. once fully formed do not *grow*. They are mere appendages, and are therefore mostly renewed by new F. being developed, and by the moulting of the previously formed plumage. Changes of colour are also observed in F., due probably to chemical action.

F. are applied to many useful and ornamental purposes, especially those of the ostrich, the rhea or American ostrich, emu, birds of the heron kind, adjutant and Marabou stork, birds of paradise, argus pheasant, and many other common birds. The plumage of the male ostrich is most esteemed, that from the back and above the wings being preferred to that of the wings and tail. These F. adorn ladies' bonnets, and form military plumes, &c. Other ornamental F. are chiefly devoted to the preparation of ladies' head-dresses, artificial flowers, wreaths, fans, ornamental screens, &c. The soft F. and light elastic down procured from swans, geese, ducks, and fowls, are extensively used for stuffing beds, cushions, &c. Russia supplies Great Britain with large quantities of goose and duck produce, and smaller quantities are obtained from Ireland and Hudson's Bay. Goose F. are most appreciated for their softness and elasticity. The down of the eider-duck is much valued for quilts on account of its warmth and softness, but its matting character when lain upon keeps it from being much used for stuffing beds. Articles of clothing are made in different countries of birds' skins. Brazilian tribes make garments of the rich and varied plumage of native birds, and the Greenlanders wear the skins of waterfowl, turning the F. to the

inside. Tippets, muffs, and many other articles used by ladies are likewise made of F. A new fabric, composed of an upper and lower layer of wool, and a thick intermediate one of down, the whole being carded together, is now manufactured in France for use as ladies' cloaks and other apparel. Spinning is performed by hand, and the wool-down is woven in the ordinary way with a warp of worsted.

Quill-pens are made from the hollow tubes of swan, goose, and crow feathers. In many parts of the world quills are employed for making ornamental baskets, cigar-cases, &c. Goose quills dyed various colours are made into ornamental articles by the Slave Indians of N. America, and in the East peacocks' quills are similarly used. The imports of F. into Great Britain during the year 1874 were as follows:—Ornamental, 273,705 lbs., valued at nearly £603,000; for beds, 2,419,984 lbs., worth about £128,000.

Feather Star (*Comatula* or *Antedon rosacea*), a species of *Crinoid* (q. v.) *Echinodermata* (q. v.), which in its earlier stages exists in a stalked condition, but in the adult state is met with as a free starfish form. The F. S. derives its name from its ten arms or rays being provided with numerous little *pinnæ* or processes, which give the arms a feathered appearance. The F. S. was formerly included in the order *Asteroidea* with ordinary starfishes, its early history being then unknown to naturalists. When first discovered in its young and attached state, it was thought to be a new form of *crinoid*, and as such was named *Pentacrinus Europæus*. But when this new crinoid was observed throughout its entire history, the star-like head was seen to detach itself from its stalk, and afterwards (as the F. S.) to live a free existence. The discovery of its early and attached condition at once showed that the F. S. was a true crinoid, and not an ordinary starfish, which is free and unattached throughout its entire existence. The arms are used by the F. S. as locomotive organs; and the internal organs are confined to the central body or *disc*, and do not, as in ordinary starfishes, send prolongations into the rays. The young or larva of the F. S. is an ovoid creature with four ciliated and transverse bands, and a small mouth and anus. The young F. S. is developed within this primitive embryo, or *pseudembryo* as it is called. The F. S. is widely distributed; it occurs in certain localities on the British coasts.

Febric'ula (Lat. 'a little fever') is a fever of short duration and mild character. The simplest form is Ephemera (q. v.), but the more severe, called *simple continued fever*, may last seventy-two or more hours. See Fever.

Feb'rifuge (Lat. *febris*, 'a fever,' and *fugo*, 'I drive away'), a medicine having the property of curing a fever, such as mineral and vegetable acids, potassæ chloras, P. citras, P. nitras, &c.

Febro'nianism is a development or a phase of Jansenism (q. v.) which made its appearance in the Roman Catholic Church in Germany towards the end of last century. It was so called after Justinus Febronius, the *nom de plume* adopted by J. H. von Hontheim in his work *On the State of the Church and the Legitimate Authority of the Roman Pontiff* (1767).

Feb'ruary, the second month of the year, was, along with January, introduced into the Roman calendar by Numa Pompilius, who allotted twenty-nine days to it, except in leap years, when it had thirty. Augustus, however, transferred one day from F. to the month named in his honour, that it might be inferior to no other month of the year. The name F. is derived from *februare*, 'to purify,' because on the 15th of F. the *Februa* or *Lupercalia*, the Roman festivals of lustration and expiation, were held. Some consider (from the coincidence of the time of year) that the Christian festival of the Purification of the Virgin on Candlemas Day was engrafted upon the Roman rite.

Feb'ruus (Lat. *februa*, 'purifications,' a word of Sabine, or according to others of Etruscan origin), an ancient Italian divinity in whose honour lustrations were celebrated on the 15th of February, which thus took its name from him. As these were supposed to produce fertility among men and beasts, Juno likewise, as the goddess of marriage, was designated Februata. F. was sometimes identified with the god of the infernal world (*Hades*), because the festival for the dead (*Feralia*) was also celebrated in February.

Fécamp, earlier **Fescan** or **Fescamp** (Lat. *Fiscanium* or *Fiscarium*), a seaport of Seine Inférieure, France, on the English Channel, 38 miles N.N.E. of Le Havre by railway. The most interesting building is the church of Notre Dame, a fine specimen of 14th c. Gothic. F. has shipbuilding yards, forges, cotton, saw, oil, and bark mills, and breweries. Its sea-baths are famous. In 1874 there cleared the port 179 ships, of 23,200 tons; 60 boats were employed in the cod-fishery. Pop. (1872) 12,534.

Fech'ner's Psycho-Physical Law. This is as follows:—'Sensations increase proportionately to the logarithms of the strength of the stimulus.' See Sensory Impressions.

Fech'ter, Charles Albert, an actor of considerable originality and brilliance of style, was born in London, October 23, 1824. His father was a German, his mother an Englishwoman, while he himself by education is practically a Frenchman. He first appeared on the Paris stage, and afterwards joining a company, travelled through Italy, played in Berlin in 1846, and in Paris and London in 1847. Returning to Paris, he made the part of Duval in the *Dame aux Camélias*, and earned a reputation which has never since declined. In 1860 he appeared at the Princess's in *Ruy Blas*, and at once took a high position on the London stage. His Hamlet (20th March 1861) created great interest, and was the topic of much discussion. Originality of conception and rejection of stage traditions were the chief characteristics of F.'s Hamlet, and constitute it, perhaps, the first of what may be called the 'new light' interpretations of Shakespeare, of which we have had several since. In 1863 he became lessee of the Lyceum Theatre, in which he produced *The Duke's Motto*, *Bel Demonio*, &c. In America, to which he removed in 1870, he has achieved a brilliant success. After making the tour of the principal cities of the States, he was for some time lessee of the Globe Theatre, Boston.

Fecia'les, an order of priests among the Romans appointed to proclaim war and to negotiate peace. The *jus feciale* was the only principle recognised by the Romans corresponding to modern international law.

Fec'ula, or **Fæc'ula** (Lat. dim. of *fæx*, 'sediment,' Fr. *fécule*), organic matter obtained as a sediment after macerating the cellular tissue of plants with water. F. is frequently employed as a synonym for Starch (q. v.).

Fed'eral Gov'ernment, in the historical sense, has been said to exist wherever the bond of union between the members is closer than that of alliance, and the degree of independence possessed by the members is greater than that of municipal freedom. In the ideal federation each of the members ought to be wholly independent in those matters (*e.g.*, criminal and constitutional law) which concern itself; while the union itself is absolute sovereign on all matters affecting all the members, being chiefly external matters of international law, questions of peace and war, diplomatic intercourse, &c. There are four great examples—the Achaian League (B.C. 281–146); the Swiss cantons, converted in 1847 from a *Staaten-bund* into a *Bundes-staat*; the Seven United Provinces of the Netherlands (A.D. 1579–1795); the United States of America (A.D. 1778). The minor confederations of ancient Greece, such as the Phokian, the Akarnanian, and the Epeirôt Leagues in the N.; the Bœotian League; and in modern times the German Confederation (1815–66), followed by the North German Confederation, are much less developed specimens of union. Of the old leagues of the thirty cities of Latium, and of other cities in ancient Italy, history relates nothing certain. The league of the Hanse towns, though now of a special and restricted kind, is perhaps the oldest living form of political union; the youngest and least promising are among the republics of S. America. The change mentioned above in the Swiss constitution indicates the fundamental distinction between the 'system of confederated states,' and the 'composite state.' In the latter the federal government acts directly on all organic questions on the subjects of every state who are truly also its own subjects. In the former it must act by the intervention of the state governments. This was tried for the first few years of American independence, but emphatically repudiated by the great leaders, Hamilton, Jay, and Madison, who wrote the *Federalist* in support of the composite state. The older principle again appeared in the German *Bund*, which was not able even to maintain an alliance in peace and war. It

had no executive power, and the arrangements as to currency and customs were really the work of Prussia. Mr. Mill has stated three conditions of useful federation—(1) A certain degree of mutual sympathy arising from common race, language, religion, political institutions; (2) that none of the members be sufficiently powerful to lose nothing by standing alone; (3) that there be no great inequality among the members. Even in the most successful federations it has been a delicate matter to preserve the balance of power between the federal government and the states. In the United States, questions on the constitution have frequently been decided in a peaceful way by the supreme court of justice; but the institution of slavery, being one naturally repugnant to civilised feeling, with its attendant questions of free soil, fugitive-slave law, &c., for a long time threatened, and at last nearly broke the Union. The American plan of a double chamber, one of which elected by a mass vote represents population, and the other elected by the legislatures of the states gives an equal representation to the states, seems wise and successful. It is always a question of circumstances whether federalism is better than an undivided government. The extent of territory, the commercial interests, the history of the inhabitants, must all be taken into account; and it must be remembered that much local autonomy, extending even to different systems of law and religion, may exist under a central monarchy. Generally, however, some great enthusiasm of race, the remembrance of a common history, devotion to a great family, or a political or religious principle, will be required to weld into unity the elements of difference. It has been suggested by Mr. Freeman that federalism combines to a certain extent the advantages of large states (viz., peace and the diminution of local prejudices and party strifes) with those of small states, of which the chief are a higher political intelligence and freedom from corruption.

Fee and Liferent (Scotch law). The first is the right of proprietorship, the second is the right to the use and profits of the subject during life. The rights may be held by one person, or they may coexist in different persons. It has been decided that a conveyance to a parent in liferent and to children unborn or unnamed in fee, imports a right of fee in the parent and a *Spes Successionis* (q.v.) only in the children. See FIAR.

Fee Fund, the name given in Scotland to the dues of court payable on the tabling of summonses, the extracting of decrees, &c. The clerks and other officers of the court are paid out of the fund.

Feel'ing. See EMOTION.

Fee-Simple. In England, a tenant in F.-S. is one who has unconditional and freehold possession of a property. He can dispose of his estate by will or deed. F.-S. is the largest interest that can be held in real property. To create it the conveyance must be to the grantee *and his heirs*, except in a will, in which equivalent expressions are admitted. The term is used in contradistinction to that of fee-tail, which is a limited tenure. See ENTAIL.

Fees in English Law Courts. All fees in courts of justice allowed by Act of Parliament are established fees, and the officers entitled to them may enforce their claim by law. Under the Supreme Court of Judicature (1875) Act, the Lord Chancellor, with the advice and consent of the judges of the supreme court, or any three of them, with concurrence of the Treasury, may fix the fees and percentages to be taken in the High Court of Justice or in the Court of Appeal, or in any court or office connected with these. The fees are to be taken in stamps, to counterfeit which is forgery, rendering the criminal liable to penal servitude.

Fees, Professional. In England it has been conclusively decided in the case of Kennedy *v.* Swinfen, that a barrister has no valid ground of action for his fees, which are given as a gratuity, not as hire; but a client cannot by law recover a fee paid to counsel, not even if he fail to attend the cause for which he has received the fee. It has been decided that it is in accordance with etiquette for a barrister to hold a brief in the county courts of England for a fee of one guinea. In Scotland it is considered that an advocate has no legal claim for a professional fee. By 21 and 22 Vict. c. 90, which applies to the United Kingdom, physicians, surgeons, and apothecaries are now entitled to recover reasonable charges, with costs of medicines and medical appliances, in any law-court. The general rule of law is that a member of any recognised profession has a legal claim for fees according to custom, if the custom be reasonable, for an unreasonable or unjust custom will not be upheld by law. In France the law with regard to legal enforcement of a barrister's claim for fees seems to be different from the English law, but from rule of the bar the result is practically the same. See RETAINER.

Fehérvár Székes (Ger. *Stuhlweissenburg*), a royal free town, and capital of the county of a same name, lies near the swamp Sár-Rét, 34 miles S.W. of Pesth by railway. Till 1527 it was the place of coronation and burial of the Hungarian kings. The seat of a bishop, F. has a cathedral, a bishop's palace, the beautiful Johanniskirche (1752), several higher schools, and a Hungarian theatre. Its manufactures are woollens, flannel, patent leather, soap, and cutlery. There are artesian wells. Pop. (1869) 22,683. F. occupies the site of the Roman *Floriana*. It suffered in the early wars with Austria, and fell in 1543, and again in 1602, into the hands of the Turks, who held it till 1688.

Feign'ed Iss'ue, in English law, is an action feigned to be brought with consent of parties to determine a question without pleading, so as to save time and costs.

Feign'ing of Disease' is of common occurrence in the army and navy, and amongst convicts and others desirous of escaping from discipline or avoiding compulsory service. In such cases it is technically called *malingering*. The diseases most commonly simulated are epilepsy, blindness, deafness, paralysis, insanity, neuralgia, and rheumatism causing lameness, &c. F. of D. is frequently practised by begging impostors, and in very many cases solely for the purpose of exciting sympathy and procuring notoriety. Detection, although difficult, is generally effected by very simple means. A little dry Scotch snuff, blown through a quill up the nostrils of a feigning epileptic, excites a fit of sneezing which may continue for an hour. When practised for a length of time, F. of D. often becomes a monomania, resulting in real mental disease, and cases are on record in which amputations have been submitted to for the removal of diseased parts, artificially produced. Feigning lunatics often become really insane.

Feint (Fr. *feindre*, 'to feign,' from the Lat. *fingere*), in warfare, is a seemingly offensive movement, usually made with the view of withdrawing the attention of the enemy from a position against which the real attack is to be made.

Feith, Rhijnvis, a Dutch poet, born February 7, 1753, at Zwoll, in Oberyssel. He studied at Leyden, became burgomaster of Zwoll, won considerable fame as a poet, was chosen member of the Institute of the Low Countries, and died in his birthplace, February 8, 1824. His chief productions are *Het Graf* ('The Grave,' Amst. 1792); a didactic poem, *De Ouderdom* ('Old Age,' Amst. 1802); *Odene n Gedichten* ('Odes and Miscellaneous Poems,' 1796–1810); *Thirza* (1791), and *Ines de Castro* (1793), tragedies; and *De Geuzen*, a patriotic lay on the water-beggars. A collection of his works appeared at Rotterdam (11 vols. 1824).

Feld'mann, Leopold, a German author of Jewish family and faith, was born at Munich, May 22, 1803. He first showed his poetical powers, according to common report, when a boy of thirteen and a cobbler's apprentice, by sending in a lady's pair of shoes which he had mended verses expressing his admiration of their owner. At the age of fourteen he produced a play, *Der Falsche Eid*. After spending a few years in trade, he was persuaded by Saphia, the poet, to throw himself into literature. His career as a man of letters has been eminently successful. The foundation of his fame was his comedy, *Der Sohn auf Reisen* (1841). In 1850 he was appointed histrionic teacher (*dramaturg*) at the National Theatre of Vienna. F.'s comedies, which are marked by spontaneity and sprightliness, have been published under the title *Deutsche Originallustspiele* (Vienna, 1844–52; 2d ed. 1855–57).

Felegyha'za, a market-town of Lesser Cumania, Hungary, on the railway between Pesth and Temesvar, 15 miles S.S.E. of Kecskemét, produces wine, fruit, and tobacco, and has cattle-markets. Pop. (1869) 21,313.

Feli'cians, the adherents of Felix, Bishop of Urgelles, in the Adoption Controversy (q. v.).

Fel'idæ or Fe'line Animals, a large family of Carnivorous mammalia, represented by the typical genus *Felis* and its varieties. It includes the lion, tiger, lynx, leopard, panther, cat, and other animals. The F. are *digitigrade Carnivora*, that is, they walk on the tips of their toes. The soles of the feet are hairy, and the metacarpus and heel are raised from the ground. The jaws are usually short, and the muscles of a great size and strength. The molar and præmolar teeth exist in fewer numbers than in any other *Carnivora*. They possess cutting edges, except the last upper molar, which is tuberculate, or provided with blunted points. The upper 'flesh' tooth (the last tooth but one in the upper jaw, and the last tooth in the lower jaw are named 'flesh teeth') in the F., has three lobes or divisions, and a blunt internal process. The lower flesh tooth has two cutting lobes. The typical arrangement of the teeth in F. is six incisors, and two canines in each jaw; six præmolars in the upper, and four in the lower jaw; and two molars in each jaw—making a total of thirty teeth. The legs are usually of equal size, and there are four toes on the hind, and five on the front feet. The toes are provided with retractile claws, which can be withdrawn at will within sheaths—an arrangement exemplified in the common cat. The tongue of the F. is rough, and its papillæ are horny; this structure fitting it to serve as a rasp in scraping the flesh from the bones of the prey. The muscular system is well developed, the bones having prominent ridges for the attachment of muscles. The F. are very generally distributed throughout the world, but attain their greatest size in tropical regions. They approach their prey stealthily, and generally spring or bound upon it from a distance. It is doubtful if any other genus than the single genus *Felis* can with good reason be constructed in this family. Many varieties of its included forms exist, but these can hardly be regarded as distinct species.

Fe'lix, the Roman procurator of Judea in the reigns of Claudius and Nero, to whom St. Paul was consigned by the chief captain at Jerusalem when his life was in danger from the Jews (Acts xxiii.). Originally a slave, he was manumitted by Claudius Cæsar, from whom he took the prænomen Claudius. He had also the surname Antonius, after Antonia, the emperor's mother. He was loaded with military honours by the emperor, and finally made procurator of Judea, in which position he indulged in all kinds of cruelty and lust, relying on his influence at court to shield him from punishment for any crime he might commit. Superseded in 62 by Porcius Festus, he was accused by the Jews, and only escaped punishment through the influence of his brother Pallas with Nero.

Popes. —**Felix I.** (about 269-274) gained an adventitious importance owing to the following circumstance. Paul of Samosata (q. v.), Bishop of Antioch, after being deposed for heresy by the Council of Antioch (269), kept possession of the Church property. The Emperor Aurelius was appealed to by the orthodox party to compel Paul to resign his office. The emperor decided that he should be bishop who was recognised as such by F., the Bishop of Rome. F. is said to have perished in the persecution under Aurelius, about 274.—**Felix II.** was an archdeacon who acceded to the wishes of the Emperor Constantius when, in 356, he banished Bishop Liberius (q. v.) because he would not agree to the condemnation of Athanasius, and was elevated to the place of Liberius. After Liberius was restored, F. was banished, and is said to have spent the rest of his life in penance for his declension to Arianism.—**Felix III.** succeeded Simplicius in 483. The Emperor Zeno had (482) put forth a formula of concord, called *Henoticon*, intended to settle the dissensions caused by the Monophysite controversy. This Henoticon, for its concessions to the Monophysites (q. v.), was rejected by F., who also attacked Acacius, Bishop of Constantinople, by whose advice Zeno had acted, and got him deposed in a council of seventy bishops held at Rome (484). Acacius was supported by the emperor and the Eastern bishops, and thus arose the first schism between the Eastern and Western Churches, which lasted thirty-four years. F. died 492. —**Felix IV.** (526-530) was raised to the papacy by Theodoric, in opposition to the wishes of the senate and the people.—**Felix V.**, who became pope in 1439, was Amadeus VIII., Duke of Savoy, being elected by the fathers at Basel, who had deposed Eugenius IV. But as the majority of the Church adhered to Eugenius, there were two popes, and also two councils, the one sitting at Basel, the other at Constance. F. resigned his high dignity in 1449, leaving the undivided papacy to Nicolaus V., who had meantime succeeded to Eugenius.

Fell'ah (Arab. 'a peasant;' plural *Fellahin*), the name of the agricultural labourer in Egypt, or of the peasant in contemptuous contradistinction to the inhabitant of the towns. They are the descendants of the ancient Egyptians, and form some three-fourths of the inhabitants. In the 7th c. they were forced to accept the religion and language of the Arabs, and the long period of their degrading toil and miserable subject condition has permanently influenced their character, habits, and appearance. They are from 5 to 6 feet in height, muscular and active, with an oval skull and a broad round face, a low retreating forehead, long deep-set eyes, large mouth, thick lips, and excellent teeth. The hands and feet, however, are of small size. A grinding system of taxation has lowered, if not broken, the spirit of the F., yet he is a brave, hardy soldier. Like the Egyptian of old, he is of grave, sustained temperament, and is distinguished equally for intelligence and immorality, sobriety and indolence. The women, who tattoo, marry often before eleven years of age. The Fellahin villages, which are scattered along the banks of the Nile and of the canals, are for the most part disorderly clusters of filthy huts, surrounding a mud-built mosque.

Fellata' (also called by the various tribes Fula, Fellani, Fulbe, &c.), the most intelligent of all the African races, now occupies a wide area in the W. of the Sudan, and includes many powerful states, as Flausse, Futa-Djalon, Senegal-Futa, Massina, &c. The F. advanced from Senegal in an easterly direction, and already in the 16th c. had spread beyond the Niger and comprised several large tribes. It was only, however, in the beginning of the 19th c. that they were stirred to conquest and to the spread of the Mohammedan religion by the Imam and reformer, Othman of Benue, on whose death (1816) the F. territory had increased to an area of 327,140 sq. miles. The people, who are of a reddish colour, and of great variety of type, are industrious and clever, but they are oppressed by a grasping aristocracy. The pop. is estimated at about 8,000,000.

Fell'enberg, Philip Emanuel von, a great improver of Swiss agriculture and education, was born of good family at Bern, 27th June 1771. After studying law at Tübingen, and travelling in different European countries, he finally devoted himself to a career of philanthropy. Purchasing the estate of Hofwyl, near his native city, he commenced a series of efforts to increase the productivity of the soil, and also to better the condition of the peasantry. He founded an asylum for forsaken children, a school of theoretical and practical agriculture, and in connection with it an institution for the education of the higher classes, which became quite famous and the model of similar institutions in other lands. F. died 21st November 1844. See Hamm, *F.'s Leben und Wirken* (Bern, 1845).

Fell'ows, Sir Charles, was born in August 1799, at Nottingham, where his father was a banker. From an early age F. took a delight in travelling, and had made himself familiar with Scotland, Switzerland, Italy, Greece, and Asia Minor, when, according to popular belief, the statement of Colonel Leake, that the valley of the Xanthus had never been explored, led him to make it the centre of archæological investigations, which he prosecuted with but slight intermissions to the end of his life. Lycia was explored by him in three different journeys in 1838, 1839, and 1841-42, the results of which were the discovery of the ruins of fifteen ancient cities, including Tlos and Xanthus, the original capital of Lycia, and the bringing home to England a great number of works of art from these cities, including twenty cases of marbles and casts, now in the Lycian Saloon of the British Museum. F., who was knighted in 1845, died November 8, 1860. For a description of his investigations see his published works, *The Xanthian Marbles* (1843); *An Account of the Ionic Trophy Monument excavated at Xanthus* (1848); *Travels and Researches in Asia Minor, particularly in the Province of Lycia* (1852), containing journals formerly published by him; and *Coins of Ancient Lycia before the Reign of Alexander* (1855).

Fell'owship, the name now applied, almost universally, to the holders of the larger endowed posts in the colleges of Oxford and Cambridge, being a translation of the 'socius' of the original statutes. The number varies in the different colleges, and

there are several other minor differences, most of which have been created within the past few years. The following is an outline of the general system. Candidates must have qualified for the degree of B.A., and the selection is determined by an open examination. The post brings with it an equal vote in the government of the college, but involves no specific duties, and has no place in the life of the university proper. As a rule, it is tenable for life, subject only to the conditions of celibacy and the absence of a specified income from other permanent sources. The average value lies between £200 and £300 per annum, and the total sum thus annually appropriated at either university is about £90,000. About two-fifths of the fellowships at Oxford are still confined to clergymen of the Church of England, but otherwise there are now no religious disqualifications. Both universities are at present undergoing reform, in which the tenure of fellowships is the chief subject of discussion. The general tendency of modern changes is to divide fellowships into two classes, viz., mere prizes, and fellowships with teaching functions; to make all alike terminable; and to relax the restriction on marriage. It has also been proposed to attach to a proportion of these posts the obligation of literary study or scientific research.

Fe'lo de Se, a verdict in English law by which it is declared that one who has committed suicide has done so in sound mind, and has thereby become a felon. Formerly, the punishment was ignominious burial in the highway, with a stake driven through the body. As the ignominy, however, could only be felt by innocent survivors, the penalty was judiciously mitigated by 4 Geo. IV. c. 32. The funeral service is, however, still omitted at interment, which by law must be within twenty-four hours after the verdict, and between nine and twelve at night. Probably the same consideration which led to mitigation of penalty may ultimately lead to abolition of it.

Fel'ony (the word *fello*, 'a felon,' is found in the Capitularies of Karl the Bald, but its origin is unknown), a term of English law denoting the higher classes of offences. Though the punishment of death may legally be inflicted for various crimes, it is now practically restricted to that of murder. Burglary, arson, and various other crimes of magnitude are usually punished with from three years' penal servitude to penal servitude for life. The chief distinction between F. and *misdemeanour* used to be, that the former occasioned the forfeiture of lands or goods, or both, at common law. This distinction has been done away with by 33 and 34 Vict. c. 23, which abolishes forfeiture or Escheat (q. v.), except in so far as consequent upon 'Outlawry' (q. v.). But conviction for F. is a disqualification for certain offices.

Fel'spar (Ger. *feldspath*, 'field-spar'), a family of minerals, the most important of all in the structure of rocks. It is divided into two groups according to the crystallisation :—(1) *Orthoclase* (Gr. 'straight-cleavage') or monoclinic F.; (2) *Plagioclase* (Gr. 'oblique-cleavage') or triclinic F. The former group, comprehending the so-called *potash* felspars, comprises the varieties adularia, rhyacolite, sanidin, orthoclase, and loxoclase, which are composed of silica, alumina, potash, and soda, in varying proportions; are coloured white, grey, or flesh-red, with sometimes greenish and bluish tints; have a vitreous lustre, and are transparent to subtranslucent. F. is taken as one of the standards of the scale of hardness, being degree 6. *Moonstone* and *sunstone*, often set in jewellery, are opalescent varieties of adularia, the latter containing minute scales of mica. The members of the second group contain lime instead of potash, and are termed *soda* or *lime* felspars, according as soda or lime predominates. Of the soda felspars, albite and oligoclase are the chief varieties, having usually a white colour, a pearly or vitreous lustre, with physical and optical properties similar to the other felspars. The type of the lime felspars is labradorite, which varies in colour from dark grey to brown, frequently relieved by the play of rich delicate tints due to internal reflections. The felspars form the basis of all true igneous rocks, the *orthoclase* varieties occurring in granite, felstone, pitchstone, obsidian, syenite, orthoclase porphyry, trachyte, and phonolyte; and the *plagioclase* varieties in porphyrite, diorite, basalt, dolerite, andesite, diallage rock, and also granite. Plagioclase granite is distinguishable from orthoclase by its usually lighter colour. Grains of F. frequently occur in sandstones, which are named the *felspathic* sandstones, in distinction to the *micaceous*, *quartzose*, and *argillaceous* sandstones. *Kaolin* (q. v.) results from the decomposition of F.—the potash and part of the silica being removed and water added.

Fel'stone, the name given by Sedgwick to a class of igneous rocks, otherwise known as petrosilex, felsite, felsite porphyry, &c., is composed of orthoclase intimately mixed with quartz. It is smooth, compact, and flinty-like, varies in colour from dark-grey to white, and has a smooth fracture.

Felt (Ger. *filz*, 'woollen cloth,' allied to the Lat. *pileus*, 'a felt hat or cap') is a kind of cloth or texture made without any process of spinning and weaving, by matting together or interlacing fibrous substances. The property of felting which is possessed by certain fibres is due to the jagged or notched character of their surfaces, which enables them by the application of pressure, combined with a certain amount of moisture, to adhere firmly and closely together, so that if the moisture and pressure are applied to a lap, or evenly spread out layer, a uniform compact cloth may be produced. A certain amount of felting power must be possessed by all fibres in order that they may adhere sufficiently to enable them to be spun, but it is only wool and certain other animal fibres that are capable of being used for F. Examples of the felting property are found in the matting which takes place in mattresses and cushions filled with woollen flocks, and in the shrinking of flannels and woollen fabrics by washing. Woollen cloths in addition to the process of weaving receive a certain amount of felting in their finish. The property of felting is chiefly turned to account in the manufacture of F. hats (see HAT MANUFACTURE), for which, in addition to wool, the hair of the rabbit, hare, nutria, musquash, and various other mammals is employed. Felted cloth is very extensively employed for making tablecovers, crumbcloths, and cheap carpetings, which generally are ornamented with printed patterns, and sometimes in the case of tablecovers embossed. The Persians produce a felted carpet in which a pattern is produced by inlaying the various colours in the substance. A heavy coarse kind of F. is very extensively used by the Russian peasantry for their winter garments, and for boots and shoes, which are moulded in a single piece. F. prepared with artificial asphalt is employed for roofing buildings.

Fel'ton, Cornelius Conway, LL.D., a distinguished American scholar, was born at West Newbury, Massachusetts, U.S., November 6, 1807. He graduated at Harvard in 1827. In 1832 he became Professor of Greek in Harvard, and in 1860 President of the College. In 1853 he paid a visit to Europe, and published his *Familiar Letters from Europe* in 1865. He died February 26, 1862. F.'s chief works are—*Homer* with English notes (1833), a translation of Menzel's *Deutsche Literatur* (3 vols. 1840), *Panegyricus* of Isocrates (1849), *Birds* of Aristophanes (1852). Along with Sears and Edwards he published *Ancient Art and Literature* (1843).

Fel'tre (Ger. *Felters*), an old town in the province of Belluno, N. Italy, on a height overlooking the Piave, 50 miles N.N.W. of Venice. It has a cathedral, considerable manufactures of silk-twist, some trade in wine, oil, and grain, and extensive bleachfields. Pop. 6000.

Felucc'a (Ital., from Arab. *fulk*, 'a ship'), a small vessel used in the Mediterranean, rigged with lateen sails, but propelled also by oars when required.

Fe'male La'bour is illegal in mines and collieries under 5 and 6 Vict. c. 99. See COAL MINES REGULATIONS ACT, FACTORY ACTS, WORKSHOP REGULATION ACT.

Female Prostitu'tion. Under 34 Edw. III. c. 1, justices of the peace may hold all to bail that are not of good fame, and compel them to give surety for their good behaviour. This ancient statute has been revived in London for the purpose of bringing the keepers of notorious brothels under magisterial notice. Any female annoying a passenger may be apprehended by the police without warrant, and is liable to a penalty of 40s.

Female Whipp'ing was abolished as a penalty by 1 Geo. IV. c. 67, imprisonment or solitary confinement being substituted.

Feme Coverte' is the English law term for a married woman. Regarding a surviving husband's interest in his wife's real estate

see COURTESY OR CURTESY. Regarding a widow's interest in her husband's estate see DOWER; see also DIVORCE, ADULTERY, MARRIAGE, DESERTION OF SPOUSE.

Fem'ern, or **Feh'marn** ('the place of cattle'), an island in the Baltic belonging formerly to Denmark but now to Prussia, separated from the N.E. point of Holstein by a narrow shallow channel, the Femersund. It is 16 miles long by 12 broad, is low and marshy, but fertile, producing much wheat and barley, which are largely exported. The fisheries are also valuable. The chief places are Burg and Petersdorf. Pop. 9600.

Feme Sole is the English law term for an unmarried woman. A married woman who by the *custom of London* trades on her own account without the husband being liable for her dealings is called a F. S. trader, because with respect to her trading her position is the same as that of a single woman. The *custom of London* is the general law of France, where any married woman can hold property irrespective of her husband and his creditors.

Fem'gerichte, or **Fæm'gerichte** (Old Ger. *fem*, 'punishment,' and *gericht*, 'a court of justice'), secret tribunals which arose during the middle ages in Westphalia, and took the place of the regular courts of justice. They seem to have grown out of the open-air meetings held by the German tribes in very early times, the notion that they took their origin from the courts held by the Missi Dominici, or imperial legates appointed by Karl the Great, being probably erroneous. Little is known of them before the end of the 12th c., when, on the deposition of the Emperor Heinrich the Lion (1180) and consequent removal of legal restraints, they were organised as a curb on feudal tyranny. They were centred in Westphalia, which was known among their members as the *Red Land*, but their influence was soon felt throughout Germany, and seems at first to have been a potent check on crime. They gradually, however, became a gigantic evil, wielding a terrible power, enhanced by the gloomy mystery which veiled them, and enforcing a system of irresponsible terrorism. Though at first the emperors made them occasional instruments of imperial designs, they grew strong enough to defy the civil government, and even on one occasion summoned the emperor to appear before them. The Pact of Westphalia in 1371 declared them lawful institutions, and during the 14th and 15th centuries their power rose to its height. In 1438 the Emperor Albrecht II. strove to abolish them; and in the second half of the 15th c. so flagrant were their evils, that in 1461 a league was formed against them by the Swiss commonwealth and several German cities and princes. In 1495 Maximilian I. made them accept a new code, which greatly weakened their authority; and on the *Landfriede* or general peace being established through Germany, and the administration of public justice secured, their influence rapidly waned, the last public F. being held at Celle, Hanover, in 1568. The secret meetings lingered on in Westphalia, though shorn of real power, until 1811, when they were suppressed by Jerome Bonaparte. The procedure at the secret meetings is somewhat obscure. The president of a court was called a *Freigraf* ('free-count'), while the members of the brotherhood who carried out his sentences were named *Freischöffen* ('free-justices') or *Scabini*. These *Freischöffen*, who at one time are said to have numbered 100,000, were also styled *Wissenden* ('wise' or 'initiated men'). At first none save a free Westphalian could be admitted into the brotherhood, but afterwards men from other districts were enrolled. They were sworn to secrecy by a terrible oath, and recognised each other by various signs, the chief of which was the mysterious S.S.G.G., whose meaning has never been revealed. The Freischöffen were bound to disclose any crime against 'the holy Fem,' or they were liable to the punishment due to the offence they had concealed. A man accused by one of the brotherhood was thrice summoned to appear by a citation secretly affixed to his door; and if he did not answer the command, was again called upon in a secret meeting named the *acht*, when, if he still disobeyed, the first Freischoff who met him was empowered to bind him to a tree, or, if he resisted, to slay him at once, in either case leaving the dagger borne by each of the members to show who had done the deed. The emperor was nominally head of the F., and the Archbishop of Köln was styled imperial lieutenant. Societies of like nature are said to have been organised in Italy. See Wigand's *Das Femgericht Westfalens* (Hamm. 1827), and Usener, *Die Frei- und heimlichen Gerichte Westfalens* (Frankf. 1832).

Fence (lit. 'that which defends' or 'guards'), a wall, hedge, or railing used for enclosing agricultural land, or for dividing it into fields. The F. most suitable for agricultural purposes consists of a rough stone dyke, but this form is only practicable in situations where stone is abundant and easily obtained. In many parts of Scotland most substantial and serviceable dykes are built from the boulders which have been removed from the fields they enclose. The lee side of a F. of this description affords excellent protection to cattle and sheep, while the F. occupies much less ground than hedges of any kind and needs no trimming. In England hedge fences are much more abundant than in Scotland, and their extent and abundance has occasioned great complaints of unnecessary waste of agricultural land. Hedges are most commonly formed of hawthorn, but the following trees and shrubs are also used:—Privet, beech, holly, crab-apple, barberry, furze, broom, maple, willow, yew, box, sweetbrier, and some others. To make and keep these living fences in an efficient condition, the plants require different methods of treatment according to their nature, and it is only in certain situations and conditions that some of them will succeed. Fences made of wooden rails and posts, or of shingles, are also very frequently employed in localities where wood is abundant and cheap, but in Great Britain it is now found to be much more economical to use fences of iron wire. These are made either entirely of iron, or the wire may be attached to wooden posts driven firmly into the ground. At certain intervals there are heavy straining posts, between which lighter posts sustain the various strands of wire in their proper relative positions. Where economy is not an object, strong fences of bar and rod iron built in short sections are employed.

Law regarding Fences.—Any one stealing any part of a live or dead F., or intentionally injuring it, is liable under statute for a first offence to a fine of £5, for a second offence to a year's imprisonment with hard labour. The Act does not apply to Scotland. In England a tenant is bound to keep fences in good repair, and with regard to them he must act according to rules of good husbandry. In Scotland a landlord is bound, without stipulation in the lease, to put fences on a farm in good repair on the entry of the tenant; but the tenant must maintain them and leave them in as good condition as when he received them. With regard to fences erected spontaneously by the tenant, it has been decided that if he is not entitled to remove them, he is not bound to repair them.

Fen'cible, a combatant or regiment of combatants levied to serve in defence of the country during a crisis, such as that of a threatened invasion. During the French war almost every country had its corps of 'Fencibles.' The name survives in the 'Royal Malta F. Artillery,' consisting in 1876-77 of 371 men of all ranks.

Fen'cing is the art of using the sword skilfully in attack or defence. It is one of the oldest of all modes of fighting, and was cultivated widely by the ancients. The Roman gladiators were well trained in handling the sword, but as they also defended themselves with armour and shields, their movements in fence were few and simple. As known in modern times, F. may be said first to have come into practice as the ponderous weapons and metal casings of feudalism were passing into disuse. During the religious wars of the Emperor Karl V., the prevailing sense of insecurity in Italy led to the general adoption of the small-sword as a safeguard by the civil classes. The Italians rapidly carried F. to great perfection, and subsequently introduced the art into Spain and France. A school was established for its prosecution in Paris, where fresh subtleties and improvements arose from day to day. The early Spanish and Italian schools generally drilled the fencer in the management of the dagger and the mantlet; to change position rapidly in avoiding attack was also regarded as necessary. But in more recent times all adjuncts were discarded in favour solely of the rapier, while the increased force and velocity of attack endangered the life of any one attempting to shift ground. As a ready and equable weapon, the rapier was long universally employed in Duelling (q. v.); and since the general abandonment of that practice, F. has continued to hold its ground firmly as an attractive, healthy pastime. In the modern exercise the Foil (q. v.) has supplanted the rapier, and the face of the fencer is defended by a strong wire mask. Space will only here permit of a description of the chief blows or thrusts and guards, together with a brief definition of

the phrases in common use. The *guard* is the wary attitude which the swordsman most naturally assumes, advancing the right foot 24 inches in front of the left, slightly bending the knees, resting the weight of the body mainly on the left leg, and holding the foil extended at the height and in front of the breast. When on guard, it is essential, by supporting the foil over the right or left breast, to *cover* the side towards which the adversary's weapon points. The guard is a passive, the *parry* an active, defence. In F., the left arm, which is extended to the rear, is of great assistance in preserving the equilibrium. The *engagement* is the act of crossing foils. There are three engagements—(1) when the blades are brought in contact on the right side; (2) when on the left; and (3) when they cross obliquely from left to right, and the points are on a level with the groin. These may be changed rapidly, but from one or other of them all blows are made. The *blow* is the act of forcibly advancing the point towards one's antagonist either by simple thrust with the arm or by the heavier lunge, in which the right foot, and consequently the upper part of the body, is thrown quickly forward. There are three main points of attack. These are (1) the breast or, as it is called, the *inside;* (2) the face, on either side of the opponent's weapon, the *outside;* and (3) the body below the sword-arm, spoken of simply as *below*. Two of these points are always exposed, it only being possible to guard one at a time. To *parry*, which is done on the forte or part of the blade nearest the handle, is to divert the thrust of an antagonist's weapon. Ten guards are regarded as affording complete protection, and these are designated by the old French ordinal numbers—prime, seconde, tierce, quarte (carte), &c. Tierce, quarte, quinte, and six are called simple parries, only requiring the weapon to be slightly moved from guard. In prime, seconde, sept, and octave, which are called half-counters, the point describes a half-circle. The two remaining are known as counters, from the weapon having to sweep a complete circle in their execution. The counter has two advantages—(1) It cuts all the lines of attack in its ellipse, and (2) it throws the opponent's weapon to the side, leaving him exposed to a direct return blow. A *double counter* is a form of parry in which two rapid counters are made consecutively; it gives great command of the weapon, and should therefore enter regularly into practice. In assault, the *feint* is of great effect, being through all its modifications merely an attempt to throw one's adversary off his guard by illusive thrusts. The *riposte* is the name given to the blow with which one follows up a successful parry. A blow delivered at the flank of the antagonist when he menaces at the 'left' is called a *flanconade*. Fencers do not tierce, or carte, &c., at the same time, but A lunges while B guards. The motion of advancing and retreating is performed by rapidly withdrawing the left foot some 18 inches, and instantly following it with the other, and *vice versa*. One must retreat as the adversary advances, unless ready to offer him the sword-point. *Appels*, or beats with the right foot on the floor, and *glissades*, or glidings of one's weapon over the adversary's, are mainly intended to confuse and lay the enemy open to thrusts.

The cavalry sword exercise is only a modification of F. adapted to horseback, and the attack and defence with the foil is the basis for that of the sabre. Bayonet exercise, as another form of F., is cruder and clumsier, but extremely formidable. See A. & C. Black's *Army Book on F.*

Fén'élon, François de Salignac de la Mothe, a great French ecclesiastic, whose name is revered throughout Christendom, was born at Fénélon in Périgord, 6th August 1651. He was descended from the Marquis de la Mothe, a well-known diplomatist during the St. Bartholomew Massacre period. At the age of fifteen he passed from the college of Plessis to the seminary of St. Sulpice, where he took holy orders in 1675. He was then made superior of the 'New Catholics,' an institution patronised by Turenne for the edification of converts in the faith. Here he remained till 1691, composing his book *De l'Éducation des Filles* (1687), and joining in Bossuet's *promenades* and *conférences* at St. Germain. He also wrote a *Réfutation du Système de Malebranche sur la Nature et la Grâce*, revised by Bossuet, and a book against the *status* of Protestant ministers, which no doubt helped to pass the revocation of the Edict of Nantes. After that event he was sent with Fleury to convert in Poitou. In 1689 he was selected as tutor for the Duke of Burgundy, heir-presumptive to the crown, for whom he wrote his *Fables*, his *Dialogues des Morts*, and also the once famous *Les Aventures de Télémaque*. He was much in the good graces of Mme. de Maintenon, who consulted him about the rules of her new institution, St. Cyr. F. became successively abbé of St. Valery, near Amiens, and Archbishop of Cambray. Now begins his connection with Quietism. This was a form of spiritualism which aimed at producing a special kind of ecstatic existence in which all the daily duties of life would be performed, but everything with the immediate sense of God's presence. The tendency of this perpetual adoration was, however, to weaken the active powers. F. became acquainted with Mme. de Guyon and Father Lacombe, and did not share the dislike of Bossuet, Bourdaloue, and other eminent divines, for doctrines of 'pure love,' &c., which, whether within the compass of human nature or not, were hardly suited for a court of which De Maintenon was the head. On Mme. de Guyon's imprisonment, F. published his *Explication des Maximes des Saints* (1697), to show authority in the recognised Christian mystics for the gradual removal from the mind of the desire of reward and the fear of punishment. This Bossuet called 'fanaticism,' and the book was submitted to examination at Rome. After sixty-four congregations had met and discussed, the votes were discovered to be equal. In the meantime, the doctors of the French Sorbonne had condemned the book, and F. lost his pension and his post of royal teacher. While Bossuet damaged his cause by the offensive personalities contained in his *Account of Quietism*, the influence of the king easily procured from Innocent XII. a special verdict of the congregation of cardinals, setting forth twenty-three propositions in F.'s book as rash, scandalous, erroneous, &c. F. at once submitted but was never reconciled to the court, which soon after tried to suppress his *Télémaque*. This work had been stolen in MS. by a servant, and published without F.'s authority. Its success over a great part of Europe was immense. F.'s archiepiscopal life at Cambray was marked by strict performance of professional duty, and a simplicity of life and real sympathy with the poor very unusual in high dignitaries of the Church. One touching fact is that during the wars he was never molested, but equally revered by the hostile armies of English, German, and Dutch. F. was a man of great sweetness, piety, and dignity of character, and these fine qualities are always conspicuous in his writings. He was disinterested even to generosity in money matters, and zealous for the welfare of his Church. He desired that the rule forbidding the Scriptures to be read in the vernacular should be relaxed, at least in his diocese; and he defended the Jesuit missionaries from the charge of having adopted the superstitions of the Chinese. About 1702 the Jansenist war broke out again on the publication of the book called *Le Cas de Conscience*. F. took part in it on the side of the Church. He also wrote on political subjects, suggesting the revival of the States General (not as representative assemblies, but as royal councils, and denying the right of civil interference claimed for the Pope. F. died 7th January 1715. The most complete editions of F.'s *Œuvres* are those of Bausset (Par. 22 vols. 1821–24) and of Gosselin (10 vols. 1853). A favourite collection is that entitled *Œuvres Choisies de F.*, containing an *Éloge* by La Harpe and a biographical and critical sketch by Villemain (Par. 6 vols. 1825; new ed. 1829). The *Correspondance de F.*, from original documents, was published by Caron (Par. 11 vols. 1827–29). See Bausset's *Histoire de F.* (Par. 3 vols. 1808.)

Fenestell'a, a genus of *Polyzoa* (q. v.) including those forms familiarly known as 'lace corals,' from their close resemblance to delicate lace, although they have no relationship to the true Corals (q. v.). The species of F. are typically Palæozoic. They begin in the Lower Silurian rocks, and extend to the Permian series, but are most frequent in Carboniferous strata.

Fe'nian (so called from the mythical *Fionna Eirinn*, an Irish national militia, levied as early as 400 B.C., but which took its name from Finn or Fioun MacCumhail, the famous hero of Irish legend) is a national association, the main object of which, formerly kept secret, but now avowed, is to overthrow English rule in Ireland in favour of a native republic. This association, the origin of which is traced chiefly to the Irish famine of 1846–47, during which so many Irish were forced to emigrate, and to the insurrectionary movements of 1848, which increased the number of enforced exiles, was organised in America and Great Britain as a society for the restoration of Irish independence in 1859. The

society was framed on the republican model. It consisted of social, district, and state 'circles,' each circle under the direction and control of a 'centre,' and the management of the whole organisation vested in a senate or 'congress.' F. congresses were held in Chicago in 1863, and in Cincinnati in 1865, and after the latter the order embraced 80,000 members in America. From this time the activity of the Fenians was unbounded, if for the most part ineffectual. In the United States several attempts were made in 1866 to invade Canada, which proved, however, ludicrous failures, and in 1867 an attempt, equally abortive, was made to create a revolution in Ireland. In September 1867 a number of daring leaders of the movement attacked a police van in Manchester, killed the officer in charge, and released the prisoners, who were under arrest for complicity in the late insurrection. The release of F. prisoners was the object of the attempt to break into Clerkenwell prison by blowing down its walls with gunpowder, an attempt attended with great destruction of life and property. At this period considerable excitement prevailed throughout England. A rising of the Irish was feared in London, and special constables were sworn in for the preservation of the peace. The number of suspected Fenians arrested from the 1st January 1867 to the 31st January 1868 was 265, of whom 95, including many most daring and influential offenders, had come from America, where having been engaged in the War of Secession, they refused to return to civil life. In May a party of 2000 invaded Canada from Vermont in the United States. They 'were ninety minutes on Canadian soil,' when they were driven back across the frontier with the loss of one man. At the close of the session of 1870 Mr. Gladstone granted an amnesty to the F. prisoners at Portland, on the condition that they should never return to the United Kingdom. In August 1871 a great meeting was held in Dublin to demand the release of the remaining F. prisoners, which resulted in a fight between the Fenians and the police, in which many persons received severe injuries. Subsequently several meetings took place for the same purpose, notably that of the 15th March 1874, when Mr. Disraeli was called to grant an amnesty to the forty prisoners then in gaol. Mr. Disraeli did not think it advisable to comply with the request; but since that date, by the natural expiry of the sentences, by the escape early in 1876 of a number of prisoners from the convict settlement of Australia, and by the liberation of others in 1878, this 'Irish grievance' has practically ceased. See Rutherford's *Secret History of the Fenian Conspiracy* (Lond. 1877).

Fenn'ec (*Vulpes Zaarensis*), a species of Carnivorous Mammalia, belonging to the family *Canidæ* (q. v.) or Dogs (q. v.), and nearly allied to the foxes. It is also known by the name of 'Zerda,' and is found in Nubia and Egypt. Its average length is about 8 inches, and the colour is a pale fawn, the base and tip of the bushy tail being black. The F. is an active little animal, and appears to subsist, notwithstanding its carnivorous nature, almost entirely upon fruits. It inhabits burrows, which it excavates in sandy places. The fur is valued by the Arabs.

Fenn'el (*Fœniculum*), a genus of *Umbelliferous* plants belonging to the Harmless or Esculent section of the order. The common F. (*F. vulgare*) appears to have originally come from S. Europe. The fruit consists of a *cremocarp*, composed of two single-seeded portions or *achenes* united by their faces, and exhibiting a ribbed appearance. Common F. attains a height of 3 or 4 feet. It is a biennial plant, and its leaves are served with fish, either whole, or in the form of a sauce. Another species is sweet F. (*F. dulce*), also named Italian F. from being cultivated in S. Europe. It yields an aromatic, and *oil of F.* is obtained from it. Other species are Cape F. (*F. Capense*) of S. Africa, and the *F. pannorium* of India. The giant F. of S. Europe belongs to the genus *Ferula*.

Fennel.

Fenn'y (*Pheni*), a river of India which rises in the hill tracts of Chittagong, Bengal province, flows between Independent Tipperah and Noakolly district on the left bank and Chittagong district on the right bank, and falls into the N.E. corner of the Bay of Bengal. It brings down much hill produce, chiefly cotton, tobacco, and timber, which pays toll to the government. Near its mouth it divides into the Big and Little F.

Fens. See BEDFORD LEVEL.

Fen'ugreek (*Trigonella*), a genus of Exogenous plants included in the natural order *Leguminosæ* (q. v.), and in the *Papilionaceous* section of that group. The plant is distinguished by the appearance of the flowers, which have a small *carina* or keel, the *alæ vexillum*, together forming the most prominent parts of the flower. The leaves are obovate, and are stipulate. The common F. (*T. fœnum Græcum*) inhabits S. Europe, but is also largely cultivated in India. The name F., or 'Greek hay,' is derived from the fact that in Greece, as well as in India, it is used as fodder. The pods are cylindrical, and recently it has been stated that the seeds are exceedingly nutritious, and might with advantage be used as a dietary. *T. incisum* is a nearly-allied species also grown in India, and *T. esculenta* affords food in the latter country. *T. ornithopodioides* is a British species, which grows in sandy soil, generally near sea-coasts.

Fen'yes, Elek', a Hungarian geographer, was born at Csokaly, 7th July 1807, studied law at Debreczin and Presburg, and sat in the Presburg diet of 1830. He then devoted himself to geography and statistics, and settled at Pesth in 1836, where he became director of the Industrial Society, and editor of two journals. During the Hungarian revolution he was appointed, in 1848, chief of the statistical department in the Ministry of the Interior. He was for some time president of the war tribunal at Pesth in 1849, and in the same year was imprisoned by the Austrians. He has since retired into private life. His works are comprehensive and accurate, and give the first reliable survey of Hungary. They were written in Magyar, but several of them have been translated into German. The chief are—*Magyarorszagnak's a hozzá kapscolt Tartománnyoknak* ('State of Hungary and the Neighbouring Countries,' Pesth, 1839-40); *Magyar-ország Statistikaja* ('Statistics of Hungary,' Pesth, 1842-43); and *Közönségés Kezi's Iscolai Atlasz* ('General School Atlas,' Pesth, 1845).

Fe'odor (the Russian form of *Theodore*, Gr. 'Gift of God') is the name of three czars.—**Feodor I.**, son of Ivan the Terrible, was born 11th May 1557, succeeded to the throne in 1587, but left the government to his brother-in-law, Boris Godunov. He died 7th January 1598, the last of the race of Rurik.—**Feodor II.**, son of Boris Godunov, reigned only for a short time, being murdered 10th June 1605. To him succeeded the first of the 'false Dimitris.'—**Feodor III.**, the son of the Czar Alexei, was born in May 1661, and ruled from 1676 to his death, 26th April 1682. He warred with varying success against the Turks and Poles. In his reign the first learned academy was founded in Russia. F. was succeeded by his brother, the famous Peter the Great.

Feodo'sia. See KAFFA.

Feoff'ment, in English law, is a grant of lands to another in fee, to him and his heirs for ever, by the actual delivery of seisin. The granter is called the *Feoffer*, he that receives is the *Feoffee*. It is the oldest form of conveyance of real property. *Livery of Seisin* is the feudal investiture on delivery of the possession of the land or tenement to another, by giving him in the former case a piece of turf from it, or twig of a tree grown on it; in the latter case, by giving the latch or key, or by some similar act. The formality has been superseded by deed of grant under 8 and 9 Vict. c. 106.

Feoffment to Uses was an artifice of the clergy to avoid the prohibitions against Mortmain (q. v.). The feudal form was applied so as to give the possession to some one as a trustee for the Church or for an ecclesiastic. The evasion was regarded favourably by the judge of the Chancery Court, who in those days was usually a priest. See USE, USES AND TRUSTS. In Scotch law, see INFEFTMENT, SASINE.

Fer'æ Natu'ræ, a term applied in English law to all kinds of beasts and birds which do not become tame or domesticated. According to Roman law these became the property of any one catching them, though it was held that no one was entitled to enter the ground of another in the chase. But a trespasser who caught his game was held to be entitled to keep it, though liable in damage to the proprietor of the land on which he trespassed. In England if *game* be found in the possession of any one trespassing, he may, under statute, be required to deliver it to the person having the right, or to his servant or gamekeeper; and if delivery be refused, the game may be taken forcibly. But the statute does not apply to animals which are not game. (See GAME LAWS.) Curious questions of common law arise as to the right of property in animals F. N. For example, the question came before the supreme Scotch law court some years ago as to the right of property in a whale which, having been harpooned by one party, had broken the attached rope, and been subsequently secured by another whaling party. Eskimo witnesses were fully examined as to local custom, and decision was given, we believe, in favour of the actual captors. A swarm of bees, if it can be identified, belongs to the owner of the parent hive. See FORESTS, SALMON-FISHING, TROUT-FISHING.

Fer de Lance (*Craspedocephalus lanceolatus*), a well-known and most virulent species of Viperine snakes, included in the Rattlesnake (q. v.) family (*Crotalidæ*). It inhabits Brazil and some islands of the W. Indies, and is commonly found in sugar plantations. A large pit exists in each side of the head between the eye and nostril, as in other members of the family *Crotalidæ*. The usual length is 5 to 6 feet. The colour is olive above, with cross markings of darker hue, and whitish grey below, the head being of a brown colour. The tail has no 'rattle,' but is provided with a spinous process. The bite of the snake is fatal usually within a few hours; and even where recovery takes place, the effects of the poison may persist for long periods.

Fer'dinand, a name borne by the sovereigns of various European countries.

German Emperors.—**Ferdinand I.**, the second son of Philipp the Handsome, Archduke of Austria and King of Castile, was born at Alcala, in Spain, in 1503. He married Anna, daughter of Ladislas VI.; and on the death of his brother-in-law, Ludwig II., at Mohacz, in 1526, he added the thrones of Bohemia and Hungary to the Austrian archduchy and the palatinate of Upper Alsace. His possession in right of his wife was, however, disputed by John Zapolya of Transylvania, seconded by Suleiman II. A long war was closed by the peace of Gross Waradein in 1538, but renewed by John Sigismund on his father's death. Named King of the Romans in 1531, F. became emperor in 1558 on the abdication of his brother Karl V. He was the last King of the Romans, or emperor elect, crowned at Aachen on the marble throne found in the tomb of Karl the Great. F., who had before oppressed the Calixtines and Lutherans in Bohemia, now urged the latter unsuccessfully to join the Council of Trent. He tried to get the sacrament in two kinds and priests' marriage from Pius IV., but failed. He died 25th July 1564. See Buchholz, *Gesch. der Regierung Kaiser F.'s I.* (10 vols. 1830–41).—His grandson, **Ferdinand II.**, born at Gratz, 9th July 1578, was the son of Archduke Karl of Carinthia and Styria, and Maria of Bavaria. He became King of Bohemia (1617) and Hungary (1618), and succeeded his cousin Matthias as emperor in 1619. His Ultramontane tendencies were well known, and there was a great revolt under Count Thorn in Bohemia, helped by Bethlen-Gabor and the Hungarians, Moravians, and Silesians. The siege of Vienna was raised, but with the approval of the Protestant Union the Bohemians elected as king Friedrich, the Elector Palatine. With the help of the Catholic League, especially of Johann Georg, Elector of Saxony, F.'s general Tilly crushed the Bohemians. The Charter of Rudolf II. was destroyed; the Reformed preachers sent out of the country, and with them thousands of the inhabitants. The alliance of Christian IV. of Denmark was, in spite of the bravery of Brunswick and Mansfield, overturned by Wallenstein, and the Peace of Lubeck (1629) was followed by the Edict of Restitution, directing the property of the Catholic clergy to be given back by the nobles, who had seized it so long ago as 1555, and excluding Protestants from the Peace of Religion. Now, however, Gustavus Adolphus was in the field, nor did the Catholic nobility relish the idea of restitution. Therefore, though Lutzen (1632) was soon followed by Nordlingen (1634), which left the Swedes almost alone in the cause of religious freedom, this edict was never properly carried out. F. died 15th February 1637. See Hurter, *Gesch. Kaisers F. II.* (11 vols. 1850–64).—**Ferdinand III.**, son of preceding, born at Gratz, 11th July 1608, succeeded his father on his imperial and royal thrones. He reluctantly continued the war against the Swedes, now backed by Richelieu, who wished to weaken the Hapsburg house. The preliminaries of Hamburg, ratified by the Congress of Münster and Osnabrück, at last led to the Peace of Westphalia (1648), just when the Swiss Wrangel had entered Prague. F. died 2d April 1657. A reform of the judicial arrangements in Germany took place during his reign. See Koch, *Gesch. des Deutsch. Reichs unter F. III.* (vol. i. 1865).

'Emperor' of Austria.—**Ferdinand I.** (Karl Leopold Franz Marcellin), eldest son of the Emperor Franz I. and Maria Theresia of Naples, was born at Vienna, 19th April 1793. He was sickly in mind and body. In 1830 he was crowned *Rex Junior* of Hungary, and next year married Maria, daughter of Victor Emmanuel of Sardinia. Succeeding his father in 1835, he left foreign affairs in the hands of Metternich, but published an amnesty for political offences in Lombardy. The insurrection in Galicia was followed by the revolutionary movement of 1847–49. F. promised a constitution, dismissed Metternich, and then in 1848 abdicated in favour of his nephew, Franz Joseph. Roads and railways were largely constructed in Austria under F.'s influence. He died 29th June 1875.

Kings of Aragon or Castile. (1) *Aragon.*—**Ferdinand I.**, the Upright, King of Aragon and Sicily, the son of Juan I. of Castile, was born in 1373. His disinterested treatment of his nephew, Juan II. of Castile, and his successes against the Moors (especially in taking the city of Antequera), secured his election from a number of competitors to the throne of Aragon in 1412. His intervention in Sicily on behalf of Blanca, widow of Martin I., was marked by the same spirit of justice and courage; and in the Church he exerted himself on the side of peace, entreating Benedict XIII. to retire, and so end the schism. F. died in 1416, and was succeeded by his son, Alfonso V. the Wise. (2) *Castile.*—**Ferdinand I.**, the Great, was a son of Sancho III., King of Navarre, who first liberated Castile from the rule of Bermuda, or Veremund, III. of Leon. F. afterwards annexed Leon and Asturias to Castile. He confirmed the ancient *fueros* of the people, and collected the code of Visigothic law. A victory gained over his brother on the 'Field of Murder' confined the power of Navarre to a territory beyond the Ebro. F. then made a brilliant campaign against the Moors. He was the founder of Castile, and styled himself Emperor. This alarmed Heinrich the Swart, German Emperor, and the Pope was called in. The 'Cid' belonged to this reign. F. died in 1065.—**Ferdinand III.**, the Pious, was born in 1199, succeeded his mother as sovereign of Castile in 1217, and his father, Alfonzo IX., as King of Leon in 1230. He suppressed the revolt of the Lara family in Castile, and then attacking the Moors in Andalusia, captured Cordova in 1236. Twelve years later Seville fell, and the Emir of Granada was compelled to pay tribute. F. died in 1252. He burned the Albigenses who had fled to him for protection, but did much to check lawlessness, and founded the famous University of Salamanca. The Archbishop Rodrigo Ximenes of Toledo wrote his biography, *Cronica del Santo Rey Don F. III.*—**Ferdinand IV.**, the son of Sancho IV., the Brave, reigned over Castile from 1295 to 1312. A great war with Portugal and Aragon, each supporting a claimant to the crown, in which the heroic Perez de Guzman fought for F., was ended by double royal alliances. In his Moorish campaigns (1305–6) F. captured Gibraltar. He was on good terms with Pope Clement V., who gave him the right to levy a tithe on Church property, and to confiscate the property of the Templar order.

Kings of Spain.—**Ferdinand V.** of Aragon, known as F. the Catholic, born 10th March 1452, was the son of Juan II., King of Navarre and Aragon. In 1468 F. was declared by his father King of Sicily, and next year, in spite of the rivalry of Alfonso V. of Portugal and Louis XI. of France, he married Isabella, Princess of Asturias, daughter of Juan II. and sister of Enrique IV. of Castile. After some years skirmishing with the French, the death of Enrique (probably by poison) permitted F. and his wife to assume the royal power in Castile. A powerful party was formed against them by the Infanta Juana *Beltraneja*, or the Bastard, daughter of Enrique, who was affianced to

Alfonso V. F. soon routed the Portuguese army at Toro, and drove the French from Roussillon. The Pope having recalled the dispensation for the marriage of Juana and Alfonso, peace was made in 1479. Internal peace was also in great measure restored by the institution in towns and villages of the *Santa Hermandad* ('holy association'), half militia, half police, to suppress crime in each district. This incidentally weakened the powers of the feudal nobility. The consolidation of the Spanish monarchy was inaugurated in Castile by the abolition of franchises and the imposition of taxes. In 1481, with the approval of Pope Sixtus IV., F. started the Inquisition, nominally to punish those Jews and Moors in Andalusia who, having taken Christian baptism, were secretly practising their old religion, but quite as much that he might strike his political enemies in the dark. Owing to the divisions among the Moors, Muley Abul Hassan and Boabdil both claiming their allegiance, it was comparatively easy for Gonzalvo of Cordova to subdue Granada. After ten years' fighting, in 1492 the Spanish dominion was assured, the Moorish claims being renounced on condition that the Moorish inhabitants should be allowed the exercise of their religion. This agreement was afterwards broken. To the great hurt of Spanish commerce, the Jews, numbering, it is said, 800,000, were also expelled from Spain, except those who accepted baptism. The policy of F. was ably carried out by his minister, Cardinal Ximenes, and the glory of his reign enhanced by the expedition of Columbus. Queen Isabella by her will left Castile to Juana the Foolish, wife of Philip the Handsome, Archduke of Austria, F. to be regent. Philip, by an armed demonstration, forced F. to resign the regency, but soon after died, and F. reobtained the regency. Always zealous for the Church, F. now made two successful expeditions into Africa, where he was acknowledged by Tunis, Algiers, and Tripoli, and also lent assistance to Pope Julius II., who suffered a heavy defeat at Ravenna. The conquest of Navarre left him master of the whole of Spain. He died at Madrigalejo, January 23, 1516. See Prescott's *History of the Reign of F. and Isabella of Spain* (1838).—**Ferdinand VII.**, born 14th October 1784, was the son of Charles IV. of Spain and Maria Louisa of Parma. Weak in mind and body, he was entirely led by his tutor Escoiquiz, who gradually formed a party round the young prince hostile to the minister Godoy (q. v.) and the queen-mother, and therefore favourable to British influences. His young wife, Maria Antonietta of Naples, died in 1806; Escoiquiz was removed from court; and for some time F. lived in wretched solitude. He then began to correspond with Napoleon. This being discovered, he was tried in the famous case at the Escurial, and all his accomplices (whose names he confessed) were exiled. The French, however, entered Spain, the Spanish troops revolted at Aranjuez, Godoy fled, Charles IV. abdicated, and F. was proclaimed king under the auspices of Murat, stationed at Madrid. Still desiring French protection, F. foolishly met Napoleon at Bayonne in 1808, the result being that it was declared the Bourbons had ceased to rule in Spain; Joseph Bonaparte became king, and F. was sent to Talleyrand's house at Valençay, where he behaved in the most undignified manner. He had, in fact, sold his country's honour for a promise of Navarre and £32,000 a year. Although Joseph reintroduced the Cortes, he could not pacify the country; guerilla leaders appeared in almost every district, and after six years' fighting F. was at the end of 1813 sent back as king on condition that he would drive out the English. The Cortes made it a further condition that he should sign the moderately Liberal constitution which had been proclaimed at Cadiz in 1812. This F. repudiated by the Valentia Decree (4th May 1814). The document was applauded by the Absolute (*Netto*) or Servilest party, and a reign of terror and darkness began in Spain. The Inquisition was recalled, and education formally put in the hands of the Jesuits; and only by the intervention of Britain were the members of the late Cortes saved from death, many of them being sent to the galleys instead. At last, in 1820, the army revolted and proclaimed the Constitution of 1812, which F. swore to observe. This constitution did not guarantee religious liberty to any extent. The king did everything in his power to enfeeble the government, refusing his *veto* without reason, and dismissing ministers whenever the Cortes met. In 1823 Louis XVIII., acting on the principles of the Holy Alliance, sent 100,000 men to the help of F. The result was that the Cortes retreated to Cadiz and dissolved, and F. at once proceeded to declare null all the solemn acts of three years. Even the advice of ultra-royalist laymen was despised by this absolute king, and in 1826 there was an *auto-da-fé* at Valencia! In 1829 F. married his fourth wife, Maria Christina of Naples, on whose suggestion he issued the decree, which has cost Spain so much blood, that women may succeed to the throne. F. died 29th September 1833. See *Memoirs of F.*, translated by Quin (Lond. 1824).

Sovereigns in Italy.—(1) *Tuscany.*—**Ferdinand I.** of Medici, third Grand Duke of Tuscany, born in 1549, was a son of Cosmo the Great. He was made a cardinal by Pius IV., and succeeded his brother Francisco in 1587. F. energetically suppressed the Tuscan brigands under Piccolomini, and with the help of the Knights of St. Stephen he cleared the Italian coast of the Moslem pirates, whom he pursued to Cyprus and Africa. His policy was that of friendship to France, for he saw Spain threatening the liberties of Italy. He therefore lent large sums to Henri IV., and sowed discord between Pope Sixtus V. and Olivares, the ambassador of Philip II. F. also had friendly relations with the Protestant princes in Germany, and the Jews and other heretics expelled from Spain found a refuge in Leghorn. Dying in 1609, he left enormous wealth to his son Cosmo.—**Ferdinand III.**, born at Florence, 6th May 1769, was the son of the Grand Duke Pietro Leopold, who became German Emperor in 1791. F. was the first Italian sovereign who recognised the French republic in 1793. In spite of this, a provisional republican government was set up in Florence, which lasted till Suwarrow drove Moreau and Macdonald from Italy. After Marengo, when Tuscany was converted into the kingdom of Etruria, F. retired to Vienna, where, as Elector of Würzburg, he was admitted into the Confederation of the Rhine. In 1814 he returned, and spent his remaining years in carrying out a humane and liberal policy. He opened up communications and organised public schools, and Tuscany was not disgraced by those harsh and secret proceedings against *Carbonari* which were seen in other Italian states. He died 17th June 1824.

(2) *Naples.*—**Ferdinand I.**, born in 1423, was the natural son of Alfonso V. the Magnanimous, of Aragon, who bequeathed Naples to F., Sicily with Aragon going to Juan. Though Pope Nicholas V. had bound himself to recognise F., Calixtus III. refused the investiture on the ground that F. was born of adultery. By a bull he also forbade recognition by any other state. The next pope, Pius II., was, however, bribed to keep his predecessor's word by the gift of the town of Beneventum. The turbulent barons, the Count Piccinino, Jean d'Anjou, Duke of Calabria (whom Charles VII. of France had made Governor of Genoa), and the Prince of Tarentum, made war on F. in 1460, and gained a decisive victory near Nola in that year. This was compensated by the victory of Troja in 1462, for which F. was indebted to Scanderbeg of Albania. In 1480 F. retook the town of Otranto from Mohammed II. He died 25th January 1494.—**Ferdinand II.** was the son of Alfonso II., and the grandson of the preceding. When Charles VIII. marched into Italy, F., deserted by Trivulzio, was beaten at Faenza and San Germano (1495) by D'Aubigny and Armagnac, and compelled to retire to Sicily. Next year the influence of F. the Catholic in the Holy League caused the French evacuation of Naples, and the re-entry of F. He died 7th October 1496.—**Ferdinand IV.** (after 1817, First of the Kingdom of the Two Sicilies), born at Naples, 12th January 1751, was the son of Don Carlos, afterwards Carlos III. of Spain. He was brought up to know nothing of public affairs, and the government was one long dispute between Tanucci, the minister, and the queen, Maria Caroline, Archduchess of Austria and a daughter of Maria Theresa. The vacillating policy of F. through the wars of the French republic met a proper end in the complete defeat of General Mack by the French in 1798, which caused the king to seek refuge on board Nelson's fleet. The population of Naples fought with desperate bravery against the disciplined troops of France, but the upper classes received them well, and tried to form a Parthenopean Republic. This exciting period has been described in Colletta's *History of Naples*, and in *Sketch of Popular Tumults* (Lond. 1837). Next year, Cardinal Ruffo and the Calabrian peasants besieged the republic in Naples, and finally F. re-entered his capital, having promised an amnesty which was at once violated by the most sweeping measures of political oppression, and unlicensed cruelty. In 1801 he arranged that a French army should again occupy part of his kingdom, and in 1805 he permitted a large army of British and Russians to land. This brought down Massena and 30,000 men, who drove out F.,

established Joseph Bonaparte, and subdued the country, except in Calabria, where opposition lingered for many years. (See Botta, *History*, book xx.) F. and the queen remained in Sicily, protected by the English fleet, till 1815, when F. resumed royal authority at Naples. In 1820 a revolt, inspired by the *Carbonari* societies, broke out. F. granted the same constitution as the Spanish Cortes had just obtained, but soon after went to a congress of the northern powers at Laybach, and returned with an Austrian army sent expressly to get rid of the troublesome constitution. He died 4th January 1825. His daughter Amelia married Louis Philippe.—**Ferdinand V.** (Second of the Two Sicilies), better known as 'Bomba,' born 12th January 1810, was the son of Francisco I., and grandson of the preceding. He began political life in 1830 by dismissing Viglia, Scaletta, and others from office, and carrying out a scheme of economy in the court and the public service. Unhappily his second marriage with Maria Theresa Isabella, daughter of the Archduke Karl, brought him more under Austrian influence. He introduced the Jesuits into Sicily, and suppressed the ancient constitution of the island. In 1840 he had a serious quarrel with Britain about the sulphur trade. The natural result of these arbitrary acts was repeated insurrection, which was cruelly punished. Ricciotti was the most popular of the leaders. The impulse of the election of Pius IX., 'the reforming pope,' at last gave to Sicily a constitution substantially the same as that of France in 1830. The example was followed on the mainland, and General Pepe marched northwards to assist the Lombards. But suddenly, on 15th May 1848, F. dissolved the Chambers, recalled everything, and by the battle of Custozza destroyed Sicily's last hope of independence. Then followed the state of things described in Mr. Gladstone's Letters—Mazza's Commission of Bastonnades, and every form of injustice. F. died 22d May 1859.

Ferenti'no, a town of Central Italy, 42 miles E.S.E. of Rome, on the Neapolitan Railway. F. is on the site of the ancient *Ferentinum*, and has a cathedral and remains of old Cyclopean walls and Roman buildings. Pop. 9096.

Fer'guson, Adam, a Scotch philosopher and author of eminence, was born at Logierait, Perthshire, 20th June 1723, and was educated for the Church at St. Andrews and Edinburgh Universities. After being for a short time chaplain to the 42d Regiment, during which he showed great gallantry at the battle of Fontenoy (1745), he settled in Edinburgh, where he became in succession Keeper of the Advocates' Library, Professor of Natural Philosophy, and (1764) Professor of Moral Philosophy. He wrote, besides other works, *Essay on the History of Civil Society* (1767), a reply to Dr. Price's work on the same subject, which resulted in his being sent out as secretary to the commission that attempted (1778-79) to bring to a peaceful close the quarrel between the American colonies and the mother country; *Institutes of Moral Philosophy* (1769); *History of the Progress and Termination of the Roman Republic* (1784), the most popular of his works, and translated almost immediately after its appearance into French and German; and *Principles of Moral and Political Science* (1792). F. died at St. Andrews, February 22, 1816.

Ferguson Bequest, The, was founded by John Ferguson of Cairnbrock, a native of Irvine, in Ayrshire, Scotland, where he died, January 8, 1856, aged sixty-nine. He left upwards of a million and a quarter sterling. Besides legacies for public purposes amounting to nearly £100,000, from one of which the Ferguson scholarships have been founded, he designed the residue of his estate, about £400,000, to form the permanent bequest fund. Its object is to aid in the erection of churches and schools, in supplementing the stipends of ministers and the salaries of missionaries and teachers of schools, and in maintaining public libraries. The benefits are confined to *quoad sacra* Established churches, Free, United Presbyterian, and Congregational churches. The annual income is upwards of £16,000. The fund is administered by trustees incorporated by Act of Parliament.

Ferguson, James, F.R.S., was born at Keith, Banffshire, 1710. Of poor parentage and little education, he early showed his mechanical talent in the construction of a wooden watch; and when engaged in tending his master's sheep spent his ample leisure time in contriving machines during the day, and in studying and mapping the stars at night. He thus attracted the attention of influential neighbours, who aided him in his mathematical studies and enabled him to go to Edinburgh, where he gained a livelihood by miniature-portrait drawing. In 1743 he removed to London, received a pension of £50 in 1760, became a Fellow of the Royal Society in 1763, and died November 16, 1776. His principal works are *Astronomy Explained on Sir Isaac Newton's Principles* (1756); *Lectures in Mechanics, Hydrostatics, Pneumatics, and Optics* (1760); *Select Mechanical Exercises* (1773); *The Art of Drawing in Perspective* (1775)—besides several papers in the *Philosophical Transactions.* Sir David Brewster re-edited several of his works. See F.'s Autobiography, prefixed to his *Select Mechanical Exercises.*

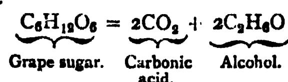
Ferguson or **Fergusson, Robert**, a poet, born at Edinburgh, September 5, 1751. He was educated at Dundee and at St. Andrews University, became clerk in an Edinburgh attorney's, and published several poems in the Scottish dialect which won considerable fame. Being thus led into society, he ruined his health by dissipation, and died insane, October 16, 1774. His poetry has a strain of pleasant fancy and humour, and is written in pure Lowland Scotch. Burns called F. his 'elder brother in the Muses,' and is said to have taken his idea of *The Cottar's Saturday Night* from *The Farmer's Ingle* of F. See F.'s works, with a biography by Dr. Irving (Glasg. 1813).

Fergusson, Sir William, Bart., F.R.S., a distinguished surgeon, was born at Prestonpans, East Lothian, March 20, 1808. Educated at Lochmaben grammar-school and at the High School and University of Edinburgh, he became assistant to Dr. Knox and Dr. Turner in the Edinburgh College of Surgeons, of which institution he was made a Licentiate in 1828 and a Fellow in 1829; began to lecture on surgery in 1831, was made Assistant-Surgeon in the Royal Infirmary in 1836, Fellow of the Royal Society, Edinburgh, in 1839, and Professor of Surgery in King's College, London, in 1840. F. was for five years Examiner in Surgery at London University, was made a baronet in 1865, and President of the Royal College of Surgeons of England in 1870. He was a Fellow of the Royal Society of London, and Sergeant-Surgeon to the Queen. F. wrote several treatises on lithotomy, aneurism, &c., and an admirable *System of Practical Surgery*, and invented many surgical instruments. He died 10th February 1877.

Feriæ (probably for *fesiæ*, from *festus*) were days of rest, holidays in which all business (especially litigation) was suspended. F. were either private or public, according as their observance was limited to families and individuals or extended to the general community. Occasions for the former class of F. were found on birthdays. The public F. were of three kinds—*Stativæ*, observed regularly every year on a fixed day, such as the Lupercalia; the *conceptivæ*, observed regularly every year, but on days fixed from year to year by the priests or magistrates, such as the *F. Latinæ*; and *imperativæ*, days fixed by the magistrates for supplication or thanksgiving, in connection with some national event. On the F. the people generally visited the temples, and offered prayers and sacrifices, and were strictly prohibited from performing any kind of work. In Old Scotch, *feriat* (also *feryale* or *feriell* tymes) denoted the immunity from prosecution secured during *harvest*, as if every day of it had been devoted to religion.

Ferin'ghees, a name applied by Mohammedans to Christians generally, and derived from the 'Franks' or 'French.' In India it is appropriated to the descendants of the early Portuguese settlers, born of native women, who have retained the Roman Catholic faith, but have in all other respects, even in colour, sunk to the condition of the surrounding native population. They are especially numerous in the neighbourhood of Dacca and Chittagong, and are chiefly employed as cultivators and domestic servants.

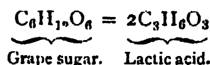
Ferish'ta or **Firish'ta, Mohammed Kasim Hindu Shah**, a Persian historian, born at Astrabad about 1570. His father travelled to Ahmednuggur in the Dekkhan, and was there made tutor to Miran Hassein, the son of Murteza Nizam Shah. F. was patronised by Murteza and Miran, and on the latter's death repaired to Bijapur, where he was highly honoured by Ibrahim Adil Shah II., and where he devoted himself to his *Tarikhi*



Firishta, or history of the Mohammedans in India. He is supposed to have died about 1612. F.'s history consists of twelve books, is clear and impartial, but takes no notice of the institutions and social state of the people. It is very popular in India, where it has completely obscured the histories on which it was founded. The work was published at Bombay in 1831, edited by J. Briggs, who issued a translation of the whole (Lond. 1832).

Ferman'agh (Ir. Gael. 'the men of Monagh,' or from *Feor-magh-eanagh*, 'the country of the lakes'), a county in the W. of Ulster, Ireland, has an area of 715 sq. miles, and a pop. (1871) of 92,794, being a decrease of 12,974 since 1861, which is accounted for principally by emigration. F. is mostly covered with wild mountains (composed chiefly of limestones and sandstones of the Old Red Sandstone period) and a network of lakes and streams, but contains rich arable land and strips of fine wood and undulating pastures. In the central depression of the uplands lie the great Lakes Erne (q. v.). The chief summits are Dowbally, 2188 feet, and Slieve Baught, 1812 feet. The Erne and its tributaries are the principal rivers. In 1871 there were 106,530 acres under tillage, 243,251 in pasture, 5909 of plantation, and 55,248 of mountain, bog, and waste. Oats and dairy produce are the chief exports. Enniskillen is the chief town. The county proper returns two members to Parliament, and is traversed by the North-Western Railway.

Fer'mat, Pierre de, a French mathematician, was born at Beaumont-de-Lomagne, near Montauban, in August 1601, and spent the most of his life as an advocate at Toulouse, where he died in January 1665. He shares with Pascal the honour of having invented the calculus of probabilities, and in his method for finding maxima and minima anticipated the differential calculus; but his reputation rests chiefly upon his ingenious investigations into the properties of numbers. A collection of his works was published by his son Samuel in 1679, at Toulouse.



Ferma'ta, in music, the name of the pause, usually indicated by the sign 𝄐.

Fermenta'tion (from the Lat. *fermento*, and that from *fervere*, 'to boil') originally signified the boiling or bubbling up of a substance attended with disengagement of gas, and not produced by the action of heat; and in this sense it was employed by the alchemists and early chemists to denote such chemical changes as the solution of metals in acids, &c. The term now, however, has a different signification, and may be defined as the decomposition or change of an organic substance in a definite manner, produced by the action of another organic substance, which does not itself suffer any change, nor lose any of its own material during the process. The latter substance is termed a *ferment*. Fermentations may be divided into two kinds:—(1) Those in which the ferment possesses a definite organised structure, and is, in fact, a plant (or possibly in some cases an animal); (2) those in which the ferment is not organised, but consists of a small quantity of an azotised substance, very often occurring along with the fermentable material. In many instances mineral substance may be substituted for the ferment of the latter order, which is sometimes called a *false ferment*. As an example of the first or true F., the conversion of sugar into alcohol—the *vinous* F.—may be instanced. This is produced by adding to a dilute solution of sugar a small quantity of yeast, and maintaining the mixture at a temperature of from 21°–26° C. Shortly after the addition of the yeast, bubbles of gas begin to be disengaged, and the yeast rapidly increases in quantity, new cells being produced by a process of budding. This action continues until the whole of the sugar is decomposed. The chief products of this F. are alcohol and carbonic acid, the latter being the gaseous substance which causes the frothing, or, as it is technically called, the *working* of the mixture. The change which occurs in the sugar may be represented by a chemical equation thus—

$$\underbrace{C_6H_{12}O_6}_{\text{Grape sugar.}} = \underbrace{2CO_2}_{\text{Carbonic acid.}} + \underbrace{2C_2H_6O}_{\text{Alcohol.}}$$

It should be observed, however, that although alcohol and carbonic acid are undoubtedly the chief products of the decomposition of the sugar, yet small quantities of several other substances are formed, of which higher homologues of alcohol, glycerine, and succinic acid may be mentioned. Another familiar instance of F. is the souring of milk. This is due to the conversion of the sugar present in milk into lactic acid, and is also brought about by the action of a special organised ferment, differing, however, entirely from the yeast plant. Its spores are introduced into the milk either from the atmosphere, or by contact with vessels which are already contaminated with them. Milk undoubtedly grows sour more rapidly in a dairy than elsewhere, no doubt from the great number of the spores of the lactic ferment present. The change attending the conversion of sugar into lactic acid may be represented as follows:—

$$\underbrace{C_6H_{12}O_6}_{\text{Grape sugar.}} = \underbrace{2C_3H_6O_3}_{\text{Lactic acid.}}$$

Of the fermentations produced by the action of a non-organised ferment, the conversion of starch into dextrin, and eventually into dextrose, may be mentioned. The ferment in this case is Diastase (q. v.), a substance produced during the germination of grain. (See BEER.) Another very remarkable instance is the change brought about by the action of emulsine on Amygdaline (q. v.), both of which substances occur in the bitter almond.

Fermented and Distilled Drink, Consumption of. There are no means available of obtaining any reliable estimate of the quantity of alcoholic beverages made and consumed throughout the world; but as in one form or other such drinks are habitually consumed in all nations, the grand total must be prodigious. From customs and excise returns a fairly accurate statement of the consumption within Great Britain and Ireland can be framed. In the seventy years lapsed from 1801 to 1871 the population of the United Kingdom almost doubled itself; while in the same period the ostensible consumption of spirits of all kinds rose from 8,800,840 gallons to 29,151,000. The quantity of malt charged with duty in 1801 was 19,643,345 bushels, and in the year ending March 1871 it reached 52,929,000 bushels. These figures would appear to indicate a very serious increase in the drink consumed in Great Britain, but they must be regarded as quite untrustworthy, seeing to what a great extent smuggling prevailed during the early part of the century. The returns for the forty years from 1830 to 1870 afford a fairer basis of contrast, and show upon the whole a decline from 1·16 gallons to 0·95 gallons per head. In the case of Scotland the decrease is very marked, amounting to over 30 per cent., thus indicating a great change in national habits. The quantity of malt charged with duty in the United Kingdom in 1830 was 32,962,000 bushels, equal to 1·62 bushels per head; and in 1871 it had risen to 52,929,392, representing still only 1·68 bushels per head. The individual consumption of malt liquors has thus remained practically stationary over a period of forty-one years. On the other hand, the consumption of wine has increased enormously, and that increase has principally taken place since the rearrangement of the wine-duties in connection with the French Commercial Treaty of 1860. The home consumption of wine, which in 1851 was 6,280,653 gallons, and in 1859 was very little more, had by the year 1869 risen to 14,168,321 gallons, the greater part of the increase consisting of light non-alcoholic French wines. The total quantity of *all* kinds of wine retained for home consumption in 1874 amounted to 17,284,242 gallons. See *Journal of the London Statistical Society* (1872).

Fermented Liquors are alcoholic beverages prepared by the fermentation of infusions of starchy or saccharine substances. A few F. L. are enumerated under the head BEER, but that most extensively consumed throughout the world is wine, which is fermented from the juice of the grape. Cider and perry are fermented from the apple and pear respectively, toddy from the sap of various palm-trees, and Mexican pulque from the *Agave Americana*. There is, however, scarcely a juicy fruit or vegetable sap from which alcoholic beverages may not be prepared. All alcoholic drinks may be divided into (1) F. L.; (2) spirits distilled from fermented infusions or saps; and (3) *liqueurs*, which are sweetened and aromatised spirits, or spirits simply aromatised.

Fer'mo (anc. *Firmum*), a town of Central Italy, in the province of Ascoli-Piceno, 4 miles from the Adriatic, and 30 miles

S.E. of Ancona. It is circled by old walls, and has a cathedral and several churches and convents, is the seat of an archbishop, and has some trade in corn, wool, and silk, chiefly carried on by the small harbour, Porto F. Pop. 8011.

Fermoy' (Ir. Gael. *Feara-muighe*, 'men of the plains'), a town of Cork, in the rich and beautiful valley of the Blackwater, 18 miles N.E. of Cork. It lies on the highroad from Cork to Dublin, and is the E. terminus of the Great Southern and Western Railway. F. stands on both sides of the Blackwater, which is here spanned by a new stone bridge. It is an important military station. The chief buildings are the barracks, for 2700 troops, the Roman Catholic cathedral, the banks, and the parish church. There is some trade in agricultural produce. Pop. (1871) 7611.

Fern, Male, the old botanical name still retained to designate the *Lastræa filix-mas*, a species of ferns, the fronds or leaves of which are bipinnate in form, the pinnules or secondary fronds being oblong and serrated. This species is common enough in Britain, and obtains its importance from its root-stem or *rhizome* being used in medicine as an anthelmintic, or remedy for tapeworm. The rhizome may attain the length of a foot.

Fern, Sweet (*Comptonia asplenifolia*), a species of plants belonging not to the Fern order (*Filices*), but to the *Myricaceæ* or Gale order, the plants of which have generally aromatic, tonic, and astringent properties. S. F. is used in N. America as an antidote to diarrhœa. Its bark is aromatic and astringent, and its leaves possess a glandular structure.

Fernan'do de Nor'onha, a wooded island, about 8 miles long, in the S. Atlantic, 220 miles N.E. of Cape St. Roque. It belongs to the empire of Brazil, and is used as a convict establishment. In one place the surface attains an elevation of 1000 feet.

Fernando Po, properly **Fernan Po** (in Portuguese *Fernão Po*), an island in the Bight of Biafra, W. coast of Africa, 44 miles long by 20 broad. Area, 800 sq. miles; pop. with that of Annabon, 5590. F. P. is the chief of the Spanish Guinea Isles, the others being Carisco, Elobey, San Juan, and Annabon. F. P. is mountainous, rising in Clarence Peak to 10,714 feet; the soil is fertile, from the number of springs and streams. Discovered by the Portuguese in 1472, and originally named *Ilha Formosa* ('the beautiful isle'), it passed in 1778 into the possession of Spain. The capital is Clarence Cove, the seat of the palm-oil trade, and a station for English steam-vessels.

Ferns (*Filices*), an important order of Acotyledonous plants, which are sometimes also named Acrogens, or 'summit growers,' from their mode of growth. They are leafy plants; the leaves, or fronds, are rolled up within the bud after the fashion of a bishop's crosier—this being named *circinate vernation*. The stem exists either in the form of a rhizome or underground stem, or in that of a hollow erect stem. The fructification is borne on the veins of the lower surface of the fronds, or on the margins of the latter. The reproductive organs consist of *sporangia* or spore cases, which may be arranged either in round *sori* or clusters, or in an elongated manner, while sometimes they are covered by a layer of the Epidermis (q. v.) or skin, termed the *indusium*, or they may be entirely destitute of any covering. Occasionally (as in *Osmunda*, the royal fern) the fructification may appear in the form of a spike on the end of a frond. The sporangia or spore cases open or burst by the contraction of an *annulus* or ring, which may encircle the spore cases in various ways. Sometimes the ring may be wanting. The spores of F., when placed in suitable conditions, germinate, and give origin, not directly to F., but to soft cellular structures, each of which is known as a *prothallus* or *pro-embryo*. On the latter, peculiar reproductive cells, supposed to correspond to the ovules and pollen of higher plants, have been found; and by the contact of these latter elements a new embryo is produced which develops into the true fern. This process reminds us of the Alternation of Generations (q. v.) seen in some animals, such as zoophytes. F. grow best in moist places and climates. They flourish in greatest perfection in tropical islands, where they attain a great size and dimensions. In New Zealand they form the characteristic flora, and from 2000 to 3000 species are known. F. have been classified into the (1) *Polypodiaceæ*, with sori borne on the back of the fronds, and covered by an indusium—genera, *Polypodium*, *Adantium*, *Pteris*, &c.; (2) *Osmundaceæ*, or flowering F., represented by the genera *Osmunda*, *Todea*, &c., in which the spore cases are dorsal, or clustered on the sides of a modified frond; (3) *Ophioglossaceæ*, the adder's-tongue tribe, with spike-like sporangia; and (4) *Danæaceæ*, with spore cases forming dorsal masses, and represented by the genera *Danæa*, *Angiopteris*, &c.

Feroz' Canal, an irrigation work in the Punjaub, British India, N.W. of Delhi, first constructed by the Moghul emperor Feroz Shah (1351-88), to water his hunting-ground at Hissar. In 1568 the works were reopened by Akbar, and further developed in 1626 by the engineer Ali Murdan Khan, under orders from Shah Jehan, to bring water to Delhi. But by 1753 the canal had again become choked, and in 1823 it was restored by the British as part of the Western Jumna Canal (q. v.). The F. C. proper, which follows the old channel, leaves the main line near Kurnal, and passes to Hansi through the districts of Kurnal, Hissar, and Rohtuck. The water here is absolutely necessary, not only for agriculture, but even for the cattle.

Fero'zepore (Ferozpur), the chief town of the district of the same name in the Punjaub, British India, 3 miles from the left bank of the river Sutlej, and 1181 miles N.W. of Calcutta. Pop. (1855), including the cantonments, 36,231. It is an ancient town, with a strong fort, and was formerly very populous. For fifteen years it was the frontier station of the British power, and the scene of many military and diplomatic events. It contains a memorial church, inscribed with the names of those who fell in the Sikh campaigns. The present streets, shops, &c., were laid out, and the fort rebuilt, by Sir H. Lawrence. The river traffic is considerable; the exports being chiefly wheat, cotton, and wool; and the imports piece goods, iron, and spices. At the time of the Mutiny, in 1857, the three regiments of sepoys stationed here were partly disarmed and partly dispersed, and the immense magazine in the fort was thus saved.—F. *district* lies along the left bank of the Sutlej, S. of the territory of the Rajah of Cashmere; area, 2692 sq. miles; pop. (1868) 549,253. When acquired by the British in 1835, the country was desolate and covered with jungle; but it is now fairly populous and cultivated. It is well watered, and in some of the marshes rice can be grown; but wheat, barley, gram, and millet are the staple crops.

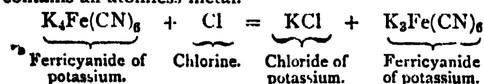
Fero'zeshah, a village in the district of Ferozepore, Punjaub, British India, 12 miles from the left bank of the Sutlej. It was the scene of the second battle of the first Sikh war, 21st December 1845, when the British, under Lord Gough and Lord Hardinge, stormed the Sikh entrenchments with great loss.

Feroz Shah, an Indian emperor of the Toghluk dynasty, reigned at Delhi from 1351 to 1388. In his reign the administration was improved and public works were lavishly undertaken. Of these last, the Feroz-Canal (q. v.) is the most celebrated; but F. is said to have constructed altogether 50 dams across rivers, 30 reservoirs, 100 caravanserais, as many hospitals and public baths, and 150 bridges. See the chronicle *Tarikh-i-Firoz Shahi* in Elliot's *History of India*, vol. iii. (Lond. 1871).

Ferr'alum, a mixture of the sulphates of iron and alumina, carbolic acid and terebine, has recently been introduced for crude deodorising purposes, where the coarser results of decomposition, such as sulphuretted hydrogen and ammonia, have to be neutralised, as in purifying drains, sewers, cesspools, urinals, stables, &c. See article by Dr. Bond, *On Some New Forms of Disinfectants* (*British Medical Journal*, February 20, 1875).

Ferra'ra (anc. *Forum-Alieni*, 'the market-place of the foreigners'), an Italian city in the province of F., on the Po di Volano, 4 miles S. of the main branch of the Po, and 26 miles N.N.E. of Bologna. It is a station on the railway from Florence to the Po. F. stands in a low unhealthy plain, is girt by walls, and consists mainly of wide and often grass-grown and deserted streets, with many crumbling palaces. In the centre of the city is a square castle of red brick, surrounded by a deep moat, the former residence of the Este family. The chief buildings are the cathedral of St. Paolo, which has a noble façade and massive campanile, and is rich in frescoes and statues; the churches of San Domenico, Campo Santo, Santa Maria del Vado, and San Benedetto, in which Ariosto was buried. These have many fine paintings, and the tombs of various artists

of F. The house of Ariosto, and the cell of Sant' Anna, in which Tasso was imprisoned, are still shown. The university, now only a school of medicine and law, was founded in 1264, and possesses a valuable library of 80,000 vols. The town has some trade in corn, and caviare is made from the sturgeons caught in the Po. Pop. (1871) 28,509. F. began to rise in the 5th c., and was included in the exarchate of Ravenna. It was a great trading city in the middle ages, and at one time numbered 100,000 inhabitants. In 1240 it fell into the power of the Este family, under whom it became famous as a seat of literature and art, and of the most splendid court in Italy. It was seized by Clement VIII. in 1597, taken by the French in 1796, restored to the Pope in 1814, held by an Austrian garrison from 1849 to 1859, and in 1860 united to the kingdom of Italy.



Ferra'ri, Gauden'zio, one of the most famous painters of the Milanese school, was born at Valdugio in 1484, and executed some remarkable frescoes and highly-finished pictures when little more than twenty years of age. Afterwards he visited Rome, worked under Raffaelle, and modelled his style upon that of the great master. His numerous works—sacred subjects with a few portraits—are for the most part in Milan. His 'St. Paul in Meditation' at Paris, his 'Martyrdom of St. Catherine,' and his magnificent 'St. Jerome' at Milan are his *chefs-d'œuvres.* F. died at Milan in 1550. His composition is noble, his expression animated and true, his drawing correct, and his colour extremely gay, though somewhat deficient in harmony and tone.

Ferrei'ra, Antonio, 'the Portuguese Horace,' was born at Lisbon in 1528, studied law at Coimbra, where he became a professor, afterwards held an office at the court of João III., and was cut off by the plague in 1569. F. was a zealous student and imitator of the Greek and Latin poets, especially of Horace. His works, which include sonnets, odes, elegies, epistles, and dramas, are marked by depth of thought and graceful conciseness of diction, and belong to the Portuguese *classic* school. F. is particularly happy in his *Cartas* or epistles. His play *Inez de Castro* was the second tragedy written in Europe after the revival of letters, and his *Cioso* was the earliest comedy of character written in Portugal. F.'s *Poemas Lusitanas* were published at Lisbon in 1598; all his works appeared at Lisbon in 1771. See Sismondi's *La Littérature du Midi* (Par. 1813).

Ferr'et (*Mustela furo*), a species of Carnivorous Mammalia nearly allied to the polecats, weasels, &c., and included with these in the Digitigrade (q. v.) family *Mustelidæ.* The F. is employed chiefly in the extermination of rats and other vermin, or hunting rabbits, its active lithe movements and its carnivorous propensities suiting it admirably for its work. The exact nature of the F. species or breed has been much disputed. Most naturalists agree in considering the F. to be an albino variety of the polecat, while a few have maintained its specific identity. The polecat and F. will breed together, but the latter appears to require a warmer climate than the former. The F. is said to have been originally brought from Africa. The common F. is the albino-like animal already alluded to, with a creamy-white body and pink eyes. The polecat-F. is larger and dark coloured. Both are very persistent and ferocious, especially if irritated. They breed twice annually, and produce from six to eight or nine young at a birth.

Ferricyan'ogen is the name given to a compound radical (or group of elements which can be transferred from one compound to another), having the composition expressed by the formula $Fe(CN)_6$.
The radical itself cannot be isolated, its compounds alone being known. Of these, the ferricyanide of potassium is the most important. This salt is prepared by the action of chlorine on ferricyanide of potassium, and differs from the latter only in that it contains an atomless metal.

$$K_4Fe(CN)_6 + Cl = KCl + K_3Fe(CN)_6$$

Ferricyanide of potassium crystallises in large prismatic bubbles, which are of a beautiful ruby-red colour. It is employed in the manufacture of *Turnbull's blue.* This compound is precipitated on mixing solutions of protosulphate of iron and ferricyanide of potassium, and when pure it has the composition expressed by the formula $Fe_3(Fe(CN)_6)_2$, and is the ferricyanide of iron or ferrous ferrocyanide. F. contains the element iron (Fe) and the group of elements called cyanogen (CN), but neither of these can be recognised in it by the ordinary test.

Ferr'ier, James Frederick, a subtle and strong metaphysician, was born at Edinburgh, November 1808. Educated at Oxford, where he took the degree of B.A. in 1832, he was called the following year to the Scotch bar, but did not practise. He became known in literature first as a contributor of articles, chiefly on metaphysical subjects, to *Blackwood's Magazine,* and his election to the chair of history in the University of Edinburgh in 1842 was followed in 1845 by his appointment to the professorship of moral philosophy in the University of St. Andrews. F.'s magazine 'studies' formed the basis of his *Institutes of Metaphysic, a Theory of Knowing and Being,* published in 1854 (3d ed. 1875), which, though cast in a mathematical form, has occasional bursts of radiant humour and paragraphs of the rarest literary beauty. It is on the whole the most keen and luminous exposition of Berkeleian idealism in the English tongue. In 1855 F., who had married a daughter of Professor John Wilson, published the collected works of his father-in-law. He died June 11, 1864. His *Lectures on Greek Philosophy,* and other philosophical remains (2 vols.), were published in 1864 (new ed. 1875), under the editorship of Sir Alexander Grant and Professor Lushington.—**Susan Edmonston F.,** aunt of the preceding, and sometimes called 'the Scottish Miss Edgeworth,' was born in Edinburgh in 1782, her father, James F., being, like Sir Walter Scott, one of the principal clerks of the Court of Session. Miss F. was herself on intimate terms of friendship with the great novelist. She first gained favour by her novel of *Marriage* (1818), which is rich in humour and in genuine portraits of Scottish character, although they occasionally verge on caricature. Her other works are *The Inheritance* (1824) and *Destiny* (1831), marked by the same enduring excellences as *Marriage.* Miss F. died 7th November 1854.

Ferr'o (Span. *Hierro*), the most westerly and the smallest inhabited island of the Canaries (q. v.). Area, 50 sq. miles. It attains a height of 3500 feet, is fruitful, but deficient in water. The chief place is the village of Valverde on the N.E. coast. All geographers at one time reckoned longitude from F., and maps are still constructed on this principle in Germany.

Ferrocyan'ogen is usually represented as having the same composition as ferricyanogen, $Fe(CN)_6$; but its salts differ from those of the latter compound, in that they contain more metal. Thus the ferrocyanide of potassium or yellow prussiate of potash has the composition expressed by the formula $K_4Fe(CN)_6$, whereas the corresponding ferricyanide is written $K_3Fe(CN)_6$. The most important compounds of F. are its potassium, iron, and copper salts. The first of these is obtained by heating animal refuse—horn, blood, clippings of hides, &c.—with carbonate of potash and scrap iron. The resulting mass is dissolved in water, filtered, and evaporated to crystallisation. Ferrocyanide of iron, or *Prussian blue,* $(Fe_2)_2(Fe(CN)6)_3$, is prepared by mixing solutions of a persalt of iron and ferrocyanide of potassium. Ferrocyanide of copper, $Cu_2Fe(CN)_6$, is called *Hatchett's brown,* and is also largely employed as a pigment; it is obtained by mixing solutions of sulphate of copper and ferrocyanide of potassium. Neither the iron nor cyanogen present in F. can be detected by the ordinary tests.

Ferr'ol (Span. *farol,* 'the beacon'), a fortified seaport in the province of Coruña, Spain, 12 miles N.E. of the town of Coruña, on a neck of land on the N. shore of the Bay or *Ria* of F., is the chief naval arsenal of Spain. The entrance to the harbour is so narrow that only a single ship of the line can pass at a time, and it is defended by the castles of San Felipe and Palma. The land side was fortified in 1769-74 with a wall on which 200 cannon can be mounted. Fifteen ships of the line could be built in F. at the same time. The arsenal is now much dilapidated, and the harbour has scarcely any mercantile importance. F. has manufactures of sailcloth, ropes, and leather. Pop. 16,640.

Ferr'otype, a photographic process published in 1844 by Mr. R. Hunt, whereby paper is sensitised by means of succinic acid, common salt, gum-arabic, and nitrate of silver; the image being developed by protosulphate of iron, and fixed by hyposulphite of soda. In the United States of America, cheap photographs on tin are called by the same name.

S.E. of Ancona. It is circled by old walls, and has a cathedral and several churches and convents, is the seat of an archbishop, and has some trade in corn, wool, and silk, chiefly carried on by the small harbour, Porto F. Pop. 8011.

Fermoy' (Ir. Gael. *Feara-muighe*, 'men of the plains'), a town of Cork, in the rich and beautiful valley of the Blackwater, 18 miles N.E. of Cork. It lies on the highroad from Cork to Dublin, and is the E. terminus of the Great Southern and Western Railway. F. stands on both sides of the Blackwater, which is here spanned by a new stone bridge. It is an important military station. The chief buildings are the barracks, for 2700 troops, the Roman Catholic cathedral, the banks, and the parish church. There is some trade in agricultural produce. Pop. (1871) 7611.

Fern, Male, the old botanical name still retained to designate the *Lastræa filix-mas*, a species of ferns, the fronds or leaves of which are bipinnate in form, the pinnules or secondary fronds being oblong and serrated. This species is common enough in Britain, and obtains its importance from its root-stem or *rhizome* being used in medicine as an anthelmintic, or remedy for tapeworm. The rhizome may attain the length of a foot.

Fern, Sweet (*Comptonia asplenifolia*), a species of plants belonging not to the Fern order (*Filices*), but to the *Myricaceæ* or Gale order, the plants of which have generally aromatic, tonic, and astringent properties. S. F. is used in N. America as an antidote to diarrhœa. Its bark is aromatic and astringent, and its leaves possess a glandular structure.

Fernan'do de Nor'onha, a wooded island, about 8 miles long, in the S. Atlantic, 220 miles N.E. of Cape St. Roque. It belongs to the empire of Brazil, and is used as a convict establishment. In one place the surface attains an elevation of 1000 feet.

Fernando Po, properly **Fernan Po** (in Portuguese *Fernão Po*), an island in the Bight of Biafra, W. coast of Africa, 44 miles long by 20 broad. Area, 800 sq. miles; pop. with that of Annabon, 5590. F. P. is the chief of the Spanish Guinea Isles, the others being Carisco, Elobey, San Juan, and Annabon. F. P. is mountainous, rising in Clarence Peak to 10,714 feet; the soil is fertile, from the number of springs and streams. Discovered by the Portuguese in 1472, and originally named *Ilha Formosa* ('the beautiful isle'), it passed in 1778 into the possession of Spain. The capital is Clarence Cove, the seat of the palm-oil trade, and a station for English steam-vessels.

Ferns (*Filices*), an important order of Acotyledonous plants, which are sometimes also named Acrogens, or 'summit growers,' from their mode of growth. They are leafy plants; the leaves, or fronds, are rolled up within the bud after the fashion of a bishop's crosier—this being named *circinate vernation*. The stem exists either in the form of a rhizome or underground stem, or in that of a hollow erect stem. The fructification is borne on the veins of the lower surface of the fronds, or on the margins of the latter. The reproductive organs consist of *sporangia* or spore cases, which may be arranged either in round *sori* or clusters, or in an elongated manner, while sometimes they are covered by a layer of the Epidermis (q. v.) or skin, termed the *indusium*, or they may be entirely destitute of any covering. Occasionally (as in *Osmunda*, the royal fern) the fructification may appear in the form of a spike on the end of a frond. The sporangia or spore cases open or burst by the contraction of an *annulus* or ring, which may encircle the spore cases in various ways. Sometimes the ring may be wanting. The spores of F., when placed in suitable conditions, germinate, and give origin, not directly to F., but to soft cellular structures, each of which is known as a *prothallus* or *pro-embryo*. On the latter, peculiar reproductive cells, supposed to correspond to the ovules and pollen of higher plants, have been found; and by the contact of these latter elements a new embryo is produced which develops into the true fern. This process reminds us of the Alternation of Generations (q. v.) seen in some animals, such as zoophytes. F. grow best in moist places and climates. They flourish in greatest perfection in tropical islands, where they attain a great size and dimensions. In New Zealand they form the characteristic flora, and from 2000 to 3000 species are known. F. have been classified into the (1) *Polypodiaceæ*, with sori borne on the back of the fronds, and covered by an indusium—genera, *Polypodium*, *Adantium*, *Pteris*, &c.; (2) *Osmundaceæ*, or flowering F., represented by the genera *Osmunda*, *Todea*, &c., in which the spore cases are dorsal, or clustered on the sides of a modified frond; (3) *Ophioglossaceæ*, the adder's-tongue tribe, with spike-like sporangia; and (4) *Danæaceæ*, with spore cases forming dorsal masses, and represented by the genera *Danæa*, *Angiopteris*, &c.

Feroz' Canal, an irrigation work in the Punjaub, British India, N.W. of Delhi, first constructed by the Moghul emperor Feroz Shah (1351–88), to water his hunting-ground at Hissar. In 1568 the works were reopened by Akbar, and further developed in 1626 by the engineer Ali Murdan Khan, under orders from Shah Jehan, to bring water to Delhi. But by 1753 the canal had again become choked, and in 1823 it was restored by the British as part of the Western Jumna Canal (q. v.). The F. C. proper, which follows the old channel, leaves the main line near Kurnal, and passes to Hansi through the districts of Kurnal, Hissar, and Rohtuck. The water here is absolutely necessary, not only for agriculture, but even for the cattle.

Fero'zepore (Ferozpur), the chief town of the district of the same name in the Punjaub, British India, 3 miles from the left bank of the river Sutlej, and 1181 miles N.W. of Calcutta. Pop. (1855), including the cantonments, 36,231. It is an ancient town, with a strong fort, and was formerly very populous. For fifteen years it was the frontier station of the British power, and the scene of many military and diplomatic events. It contains a memorial church, inscribed with the names of those who fell in the Sikh campaigns. The present streets, shops, &c., were laid out, and the fort rebuilt, by Sir H. Lawrence. The river traffic is considerable; the exports being chiefly wheat, cotton, and wool; and the imports piece goods, iron, and spices. At the time of the Mutiny, in 1857, the three regiments of sepoys stationed here were partly disarmed and partly dispersed, and the immense magazine in the fort was thus saved.—F. *district* lies along the left bank of the Sutlej, S. of the territory of the Rajah of Cashmere; area, 2692 sq. miles; pop. (1868) 549,253. When acquired by the British in 1835, the country was desolate and covered with jungle; but it is now fairly populous and cultivated. It is well watered, and in some of the marshes rice can be grown; but wheat, barley, gram, and millet are the staple crops.

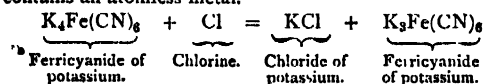
Fero'zeshah, a village in the district of Ferozepore, Punjaub, British India, 12 miles from the left bank of the Sutlej. It was the scene of the second battle of the first Sikh war, 21st December 1845, when the British, under Lord Gough and Lord Hardinge, stormed the Sikh entrenchments with great loss.

Feroz Shah, an Indian emperor of the Toghluk dynasty, reigned at Delhi from 1351 to 1388. In his reign the administration was improved and public works were lavishly undertaken. Of these last, the Feroz-Canal (q. v.) is the most celebrated; but F. is said to have constructed altogether 50 dams across rivers, 30 reservoirs, 100 caravanserais, as many hospitals and public baths, and 150 bridges. See the chronicle *Tarikh-i-Firoz Shahi* in Elliot's *History of India*, vol. iii. (Lond. 1871).

Ferr'alum, a mixture of the sulphates of iron and alumina, carbolic acid and terebine, has recently been introduced for crude deodorising purposes, where the coarser results of decomposition, such as sulphuretted hydrogen and ammonia, have to be neutralised, as in purifying drains, sewers, cesspools, urinals, stables, &c. See article by Dr. Bond, *On Some New Forms of Disinfectants* (*British Medical Journal*, February 20, 1875).

Ferra'ra (anc. *Forum-Alieni*, 'the market-place of the foreigners'), an Italian city in the province of F., on the Po di Volano, 4 miles S. of the main branch of the Po, and 26 miles N.N.E. of Bologna. It is a station on the railway from Florence to the Po. F. stands in a low unhealthy plain, is girt by walls, and consists mainly of wide and often grass-grown and deserted streets, with many crumbling palaces. In the centre of the city is a square castle of red brick, surrounded by a deep moat, the former residence of the Este family. The chief buildings are the cathedral of St. Paolo, which has a noble façade and massive campanile, and is rich in frescoes and statues; the churches of San Domenico, Campo Santo, Santa Maria del Vado, and San Benedetto, in which Ariosto was buried. These have many fine paintings, and the tombs of various artists

of F. The house of Ariosto, and the cell of Sant' Anna, in which Tasso was imprisoned, are still shown. The university, now only a school of medicine and law, was founded in 1264, and possesses a valuable library of 80,000 vols. The town has some trade in corn, and caviare is made from the sturgeons caught in the Po. Pop. (1871) 28,509. F. began to rise in the 5th c., and was included in the exarchate of Ravenna. It was a great trading city in the middle ages, and at one time numbered 100,000 inhabitants. In 1240 it fell into the power of the Este family, under whom it became famous as a seat of literature and art, and of the most splendid court in Italy. It was seized by Clement VIII. in 1597, taken by the French in 1796, restored to the Pope in 1814, held by an Austrian garrison from 1849 to 1859, and in 1860 united to the kingdom of Italy.



Ferra'ri, Gauden'zio, one of the most famous painters of the Milanese school, was born at Valdugio in 1484, and executed some remarkable frescoes and highly-finished pictures when little more than twenty years of age. Afterwards he visited Rome, worked under Raffaelle, and modelled his style upon that of the great master. His numerous works—sacred subjects with a few portraits—are for the most part in Milan. His 'St. Paul in Meditation' at Paris, his 'Martyrdom of St. Catherine,' and his magnificent 'St. Jerome' at Milan are his *chefs-d'œuvres*. F. died at Milan in 1550. His composition is noble, his expression animated and true, his drawing correct, and his colour extremely gay, though somewhat deficient in harmony and tone.

Ferrei'ra, Antonio, 'the Portuguese Horace,' was born at Lisbon in 1528, studied law at Coimbra, where he became a professor, afterwards held an office at the court of João III., and was cut off by the plague in 1569. F. was a zealous student and imitator of the Greek and Latin poets, especially of Horace. His works, which include sonnets, odes, elegies, epistles, and dramas, are marked by depth of thought and graceful conciseness of diction, and belong to the Portuguese *classic* school. Both are very persistent and ferocious, especially if irritated. They breed twice annually, and produce from six to eight or nine young at a birth.

Ferricyan'ogen is the name given to a compound radical (or group of elements which can be transferred from one compound to another), having the composition expressed by the formula $Fe(CN)_6$.

The radical itself cannot be isolated, its compounds alone being known. Of these, the ferricyanide of potassium is the most important. This salt is prepared by the action of chlorine on ferricyanide of potassium, and differs from the latter only in that it contains an atomless metal.

Ferricyanide of potassium crystallises in large prismatic bubbles, which are of a beautiful ruby-red colour. It is employed in the manufacture of *Turnbull's blue*. This compound is precipitated on mixing solutions of protosulphate of iron and ferricyanide of potassium, and when pure it has the composition expressed by the formula $Fe_3(Fe(CN)_6)_2$, and is the ferricyanide of iron or ferrous ferrocyanide. F. contains the element iron (Fe) and the group of elements called cyanogen (CN), but neither of these can be recognised in it by the ordinary test.

Ferr'ier, James Frederick, a subtle and strong metaphysician, was born at Edinburgh, November 1808. Educated at Oxford, where he took the degree of B.A. in 1832, he was called the following year to the Scotch bar, but did not practise. He became known in literature first as a contributor of articles, chiefly on metaphysical subjects, to *Blackwood's Magazine*, and his election to the chair of history in the University of Edinburgh in 1842 was followed in 1845 by his appointment to the professorship of moral philosophy in the University of St. Andrews. F.'s magazine 'studies' formed the basis of his *Institutes of Metaphysic, a Theory of Knowing and Being*, published in 1854 (3d ed. 1875), which, though cast in a mathematical form, has occasional bursts of radiant humour and paragraphs of the rarest literary beauty. It is on the whole the most keen and luminous exposition of Berkeleian idealism in the English tongue. In 1855 F., who had married a daughter of Professor John Wilson, published the collected works of his father-in-law. He died June 11, 1864. His *Lectures on Greek Philosophy*, and other philosophical remains (2 vols.), were published in 1864 (new ed. 1875), under the editorship of Sir Alexander Grant and Professor Lushington.—**Susan Edmonston F.**, aunt of the preceding, and sometimes called 'the Scottish Miss Edgeworth,' was born in Edinburgh in 1782, her father, James F., being, like Sir Walter Scott, one of the principal clerks of the Court of Session. Miss F. was herself on intimate terms of friendship with the great novelist. She first gained favour by her novel of *Marriage* (1818), which is rich in humour and in genuine portraits of Scottish character, although they occasionally verge on caricature. Her other works are *The Inheritance* (1824) and *Destiny* (1831), marked by the same enduring excellences as *Marriage*. Miss F. died 7th November 1854.

Ferr'o (Span. *Hierro*), the most westerly and the smallest inhabited island of the Canaries (q. v.). Area, 50 sq. miles. It attains a height of 3500 feet, is fruitful, but deficient in water. The chief place is the village of Valverde on the N.E. coast. All geographers at one time reckoned longitude from F., and maps are still constructed on this principle in Germany.

Ferrocyan'ogen is usually represented as having the same composition as ferricyanogen, $Fe(CN)_6$; but its salts differ from those of the latter compound, in that they contain more metal. Thus the ferrocyanide of potassium or yellow prussiate of potash has the composition expressed by the formula $K_4Fe(CN)_6$, whereas the corresponding ferricyanide is written $K_3Fe(CN)_6$. The most important compounds of F. are its potassium, iron, and copper salts. The first of these is obtained by heating animal refuse—horn, blood, clippings of hides, &c.—with carbonate of potash and scrap iron. The resulting mass is dissolved in water, filtered, and evaporated to crystallisation. Ferrocyanide of iron, or *Prussian blue*, $(Fe_2)_2(Fe(CN)6)_3$, is prepared by mixing solutions of a persalt of iron and ferrocyanide of potassium. Ferrocyanide of copper, $Cu_2Fe(CN)_6$, is called *Hatchett's brown*, and is also largely employed as a pigment; it is obtained by mixing solutions of sulphate of copper and ferrocyanide of potassium. Neither the iron nor cyanogen present in F. can be detected by the ordinary tests.

Ferr'ol (Span. *farol*, 'the beacon'), a fortified seaport in the province of Coruña, Spain, 12 miles N.E. of the town of Coruña, on a neck of land on the N. shore of the Bay or *Ria* of F., is the chief naval arsenal of Spain. The entrance to the harbour is so narrow that only a single ship of the line can pass at a time, and it is defended by the castles of San Felipe and Palma. The land side was fortified in 1769-74 with a wall on which 200 cannon can be mounted. Fifteen ships of the line could be built in F. at the same time. The arsenal is now much dilapidated, and the harbour has scarcely any mercantile importance. F. has manufactures of sailcloth, ropes, and leather. Pop. 16,640.

Ferr'otype, a photographic process published in 1844 by Mr. R. Hunt, whereby paper is sensitised by means of succinic acid, common salt, gum-arabic, and nitrate of silver; the image being developed by protosulphate of iron, and fixed by hyposulphite of soda. In the United States of America, cheap photographs on tin are called by the same name.

Ferru'ginous (from Lat. *ferrum*, 'iron'), a term in geology applied to rocks and soils which contain large quantities of red iron oxide. Its presence is easily recognised by the brownish-red colour which prevails.

Ferr'y (from Old Eng. *faran*, 'to move;' *cf.* Lat. *fero*), in law, is a right by prescription or by grant from the crown to keep a passage-boat on water, and to make a reasonable charge for the conveyance by it of passengers or goods. The right prevents another from setting up another F. in the same neighbourhood. It is not essential to a right of F. that the possessor should be the proprietor of the land on either side. By 8 and 9 Vict. c. 45, certain rules are laid down for the regulation of ferries.

Fertil'ity is the capability of producing progeny. This capability varies very much in the animal kingdom. It has been estimated by Leuckart that 'the yearly generative expenditure of the female organism is in the human female about one-fourteenth of the body weight, in the sow about one-half, in the mouse about three times the body weight, in the bee five times, and in the queen bee 110 times the body weight.' These facts indicate the tear and wear of the female body in these animals during reproduction. Another mode of estimating F. would be to note the number of real progeny resulting. This can rarely be done, but it may be stated generally that the number of the progeny stands in a certain relation to the mean duration of life of the species. The greater the mean duration of life the less will be the F., and *vice versâ*. The F. of the human being is affected by social influences and habits in a manner at present not understood.

Fescenn'ine Verses (from Lat. *fascinum*, 'a bewitching,' as they were supposed to be a protection against witchcraft) were the earliest attempt at versification made by the inhabitants of Italy. They were a rude kind of dramatic satire, in which the interlocutors ridiculed one another, and they were accompanied by music and dancing. In course of time they became malicious and libellous in character. At first they were confined to rustic gatherings, especially after harvest, but were subsequently introduced, probably in a more refined form, into the towns. It is a common error to suppose that the F. V. were of Etrurian origin, and that the name was derived from Fescennia, an Etrurian town.

Fesch, Joseph, Cardinal, an eminent ecclesiastic, who from the marriage of his father to the grandmother of the First Napoleon was considered uncle of the latter, was born at Ajaccio, January 3, 1763. He was educated for the Church of Rome, but entering into the spirit of the French Revolution, served in the army under General Montespan as storekeeper. When his nephew resolved to revive the Roman Catholic worship in France and to gain the favour of the Pope, he made use of F., who returned to his original profession, and proved himself an adroit and successful ecclesiastic. In 1802 he became Archbishop of Lyon; in 1803 he obtained a cardinal's hat; and in 1804, while ambassador at Rome, he induced the Pope to consecrate Napoleon as emperor. F., however, was too staunch a Churchman to approve of the policy which his nephew pursued towards the Pope; he declined to be made Archbishop of Paris; Eugène Beauharnais was preferred to him for the primacy of the Confederation of the Rhine, which he had been promised; and he retired with his half-sister Letitia to Rome. His later years were embittered by the persecutions of the Legitimist clergy, who compelled him to resign his charge. F. died May 13, 1839, leaving behind him one of the largest collections of paintings ever made by one person. See *Le Cardinal F., Fragments Biographiques* (Lyon, 1841), and *La Vérité sur le Cardinal F.* (Lyon, 1842). Napoleon's Correspondence with F. was published by Du Casse (2 vols. Par. 1855).

Fes'cue (*Festuca*), a genus of Grasses represented by various characteristic British species, and possessing spikelets with many flowers or florets, each floret having two lanceolate paleæ. The meadow F. (*F. pratensis*) attains a height of 2 or 3 feet, and is common in meadows and pastures in Europe, N. America, and N. Asia. The panicle in this species is of spreading form, and the spikelets are arranged in linear fashion. Spiked F. (*F. loliacea*) has the branches of the panicle represented by a single spikelet, and has a *raceme* arrangement of florets, or two-rowed spikes. It is otherwise nearly allied to the former species. *F. duriuscula*, or hard F., grows well on dry soils, and has a shortened panicle. Creeping or red F. (*F. rubra*) is allied to the preceding species, and is also of hardy nature. A smaller species is sheep F., or *F. ovina*, most common in hilly districts. Tall F. (*F. elatior*) may attain a height of 4 or 5 feet. It grows most profusely in moist soil, and near rivers and lakes. *F. heterophylla* is a native of the Continent, but has been cultivated with success in Britain; and *F. quadridentata* of Peru is used in that country for thatching roofs.

Fesse, in heraldry, one of the honourable ordinaries, is formed by two parallel lines drawn horizontally across the centre of the shield, so as to contain two-thirds, and is regarded as an emblem of the military girdle worn by mediæval knights. *Fess-point* is the centre of the shield; *F.-wise*, placed like a F.

Fess'enden, William Pitt, was born at Boscawen, New Hampshire, U.S., October 16, 1806. He graduated at Bowdoin College in 1823, established himself as a lawyer in Portland, Maine, in 1829, and soon acquired a high reputation in his profession. F. entered political life as a Whig, and was elected to the state legislature in 1832. In 1841 he was sent as representative to Congress; entered the United States Senate in 1854, and signalised himself by an able speech against the Nebraska bill. He became a leading Republican, and as chairman of the finance committee rendered invaluable service during the war. In 1864 he became Secretary of Treasury, but returned the following year to the Senate, where he voted for the acquittal of President Johnson. After suffering long from ill-health, he died September 8, 1869. F. was an eloquent debater, a skilful tactician, an able statesman, and a man of strict probity and honour.

Fes'tival Plays. See MYSTERIES, MORALITIES, AND MIRACLE PLAYS.

Festivals are, speaking generally, holy-days or 'solemn assemblies celebrated by cessation from labour, sacrifices, feasting, dancing, singing, or any other sign of joy.' They have been instituted chiefly from four causes:—First, in honour of the gods, for offering sacrifices and praises to them, out of gratitude for benefits received; secondly, in order to propitiate the gods, so as to obtain some particular blessings or deliverance from evils under which men were labouring; thirdly, in memory of deceased patriots or public benefactors; and fourthly, as times of rest and recreation to labourers. Perhaps the earliest of all F. were those connected with agriculture, as after harvest or vintage, when men rejoiced over the fruits they had gathered, eating and drinking plentifully. Astronomical phenomena would also be early observed, such as the moon's changes, the summer and winter solstices, &c., and F. celebrated in connection with them. Such celebrations have always had great attractions for primitive, half-civilised peoples, and have been of universal prevalence. The nation which was specially noted in ancient times for its attention to F. was the Egyptians, from whom probably the Greeks derived theirs to a great extent, the Romans again deriving theirs from the Greeks.

Greek and Roman Festivals.—The four great solemn F. of Greece were the Olympic, Pythian, Isthmian, and Nemean. The following, from their importance, also deserve notice:—The Adonia, in honour of Venus and Adonis; the Apaturia, of Bacchus; the Brauronia, of Diana Brauronia; the Dionysia, of Bacchus; the Eleusinia, of Ceres and Proserpine; the Thesmophoria, of Ceres the lawgiver; and the Panathenaia, of Minerva. F. to the same god were held in different localities, as the Apollonia at Sicyon, the Carneia at Sparta, the Daphnephoria at Thebes, the Delia at Delos—all in honour of Apollo. The Androgeonia and the Arateia (after Androgeus and Aratus) are examples of the numerous F. instituted in honour of heroes. The Romans freely enriched their mythology by foreign additions, but their F. were not at all so numerous as the Greek, never, indeed, having amounted to more than a hundred. The Epulum Jovis was held on the 13th November; the Matronalia, in honour of Juno, on the 1st March; the Quinquatrus, of Minerva, on the 19th March; and the other great gods were similarly honoured. Other notable sacred F. were the Cerealia, in honour of Ceres; the Consualia, of Consus, the god of secret deliberation; Matralia, of Mater Matula, or Aurora; Lupercalia, of Lupercus, the god of fertility, &c., &c. The Larentalia, in honour of Acca Larentia, nurse of Romulus and Remus, is an example of the F. that commemorated historical personages or events. Among the Romans, public

games in the earlier ages were always regarded as religious rites. The chief athletic sports were the races, the mock fight (called the game of Troy), sham battles, sea-fights, and wild beast hunts.

The Hebrew F. may be divided into the Mosaic and post-exilian. 1. *Mosaic.*—The former are all connected with the sacred astronomical number *seven* (see WEEK), especially a series directly counted by sevens: (1) the Sabbath (q. v.) of Days; (2) the Sabbath of Weeks (see PENTECOST, FEAST OF); (3) the Sabbath of Months, kept on the first day of the 7th month (Tishri) as the beginning of the New Year, and called the Feast of Trumpets (Lev. xxiii. 23-25; Num. xxix. 1-6); (4) the Sabbath of Years, kept every seventh year as a year of remission (Exod. xxiii. 11; Lev. xxv. 1-7); (5) the Sabbath of Sabbath-years, kept every seven Sabbath-years, and called the year of Jubilee (q. v.). Besides these there were—(6) the Feast of the New Moon, kept at the beginning of every month, to connect the reckoning of weeks with the lunar month (Num. x. 10, xxviii. 11-15); (7) the Passover (q. v.), which had two real festival ('holy convocation') days—the first and seventh—and which was connected with the beginning of the harvest; (8) the Great Day of Atonement, on the 10th of the seventh month, which was a *fast* as well as a festival (Lev. xvi., xxiii. 26-32; Num. xxix. 7-11); (9) the Feast of Tabernacles (q. v.), or of the ingathering of the harvest; and (10) the feast which follows immediately on the Feast of Tabernacles, on the 23d Tishri (Num. xxix. 35-38). The annual F. also made up the sacred number seven, with their days of 'holy convocation' (*two* Passover, one Pentecost, Trumpets, Atonement, Tabernacles, and concluding festival), and of these seven the Great Day of Atonement was pre-eminent as the 'Sabbath of Sabbaths,' as the ordinary Sabbath was pre-eminent among the seven days of the week.

2. *The post-exilian* F. were all annual, and in their order in the year were as follows:- (1) The Feast of Acra, instituted by Simon Maccabæus, 141 B.C., and held on the 23d of the 2d month, in commemoration of the capture of Acra and the expulsion of the Hellenists from Jerusalem; (2) the Feast of Wood-carrying, kept on the 15th of the 5th month from the time of the return from Babylon (Neh. x. 35); (3) the Feast of Water-drawing, held on the 22d of the 7th month, the last day of the Feast of Tabernacles (*cf.* John vii. 37); (4) the Feast of Dedication (beginning on the 25th of the 8th month, and lasting eight days), instituted by Judas Maccabæus in commemoration of the purifying of the Temple (1 Macc. iv. 52-59; Jos. *Ant.* xii. 7, 7); (5) the Feast of Nicanor, insituted by Judas Maccabæus, and held on the 13th of the 12th month, in commemoration of the victory gained over Nicanor (1 Macc. vii. 49; Jos. *Ant.* xii. 10, 5); (6) the Feast of Purim, on the 14th of the 12th month, in commemoration of the deliverance of the Jews related in the Book of Esther (*cf.* iii. 7, ix. 20-28).

During the first few years of the existence of the Christian Church many of the Jewish F. were doubtless observed. As time went on the influence of Judaism diminished, and all Jewish F. were rejected except those which had been Christianised. At the end of the 2d c. there is no evidence of the existence of any other Christian F. than the Sabbath or Lord's Day, the Passover—observed as Good Friday (q. v.)—and Easter (q. v.), and Pentecost (q. v.). But gradually other F. were adopted, perhaps a good deal owing to the analogy of other religions. The earliest of these was Epiphany (q. v.), and then Christmas (q. v.) came to be observed as a separate festival. Ascension Day (q. v.) began to be observed in the 3d or 4th c., and the F. of the Presentation—Candlemas (q. v.)—and Annunciation in the 6th c. A very fruitful source of F. was the observance of the anniversaries of martyrs' deaths, reckoned as their birthdays (*i.e.*, their entrance into life), of which kind there was a widespread observance by the end of the 4th c. At first these saints'-days had only a local celebration, but in course of time those of the more eminent saints were celebrated by the whole Church. In the 7th c. a festival was instituted in honour of the Cross. At this time also (610), Pope Boniface IV., having got a gift of the Pantheon at Rome, which had been dedicated to Cybele and all the gods, dedicated it to the Virgin Mary and all the holy martyrs, and instituted the festival of All Saints (q. v.), which, however, had been observed in the Eastern Church from the 4th c. To this was added in the 10th c. the festival in memory of all departed souls.

The F. of the English Church are 149 in number (including Sundays):—sixty-three in honour of Christ, three of the Holy Ghost, one of the Trinity, one of the angels, five of the Virgin Mary, and seventy-six of saints. As the day on which Easter falls varies from year to year, those F. which depend upon Easter—Septuagesima, Rogation Sunday, Ascension Day, Whitsunday, Trinity Sunday, Ash-Wednesday—are also 'movable feasts.' See C. D. Ginsburg in Kitto's *Cyclo. of Bib. Lit.* (new ed. Edinb. 1863); Smith's *Dict. of Christ. Ants.* (Lond. 1875); Blunt's *Annotated Book of Com. Prayer* (6th ed. 1872); Bingham's *Ecclesiast. Antiquities.*

Festoon', an architectural ornament, frequently occurring on the friezes of Roman and Renaissance buildings, and consisting usually of wreaths of flowers and fruit, alternating with heads of animals. In modern architecture the F. is much used as a decoration for cornices, panels, &c.

Fes'tus, Sex'tus Pompei'us, who is supposed to have lived in the 3d or 4th c. A.D., was the compiler of a valuable work in twenty books, entitled *De Verborum Significatione.* This work was a dictionary of notable Latin words, and consisted chiefly of an abstract of the *De Significatu Verborum* by Valerius Flaccus, an eminent grammarian of the time of Augustus. The epitome of F. was still further abridged by Paulus Diaconus, towards the close of the 8th c. Only one MS. of the work of F. has survived, the numerous blanks in which were filled up by Scaliger and Ursinus from Paulus, and from conjecture. The best edition is that of Müller (Leips. 1839).

Fesz'ler, Ignaz Aurelius, a Hungarian novelist and historian, born at Czorendorf in July 1756, joined the Capuchins, but afterwards became a Protestant, was reader to the Emperor Joseph in 1784, and from 1785-87 Professor of Oriental Languages at Lemberg. Being accused of atheism, he betook himself to Silesia, and finally to St. Petersburg, where he received the chair of Eastern languages in 1809, and died December 15, 1839. He wrote various novels, treatises, &c.; but his chief works, which are all in German, are *Marc-Aurel*, a romance (1790-92), *Mathias Corvinus* (1793), *Attila* (1794), and *Geschichte der Ungarn* (Leips. 1812-25). F. was a deep scholar and graceful writer. See his interesting autobiography, *Rückblicke auf meine 70 jährige Pilgerschaft* (Bresl. 1826).

Fetia'les. See FECIALES.

Fe'tichism, meaning the worship of fetiches (*fetich* is a corruption of the Portuguese *feitiçâo*, 'magic,' from the Lat. *ficticius*, 'what is feigned,' or perhaps from *fatidicus*, 'fate-telling'), is the first form of belief in the supernatural adopted by men altogether uncivilised. It is purely a worship of nature, the fetiches being natural objects, such as beasts, birds, reptiles, fishes, insects, trees, mountains, lakes, rivers, gems, metals, meteoric stones, the sun, moon, and stars, the earth, sea, and air, as well as artificial imitations of natural objects, which are credited with having a supernatural influence, and are appealed to by sacrifices and prayers against sickness, drought, &c., to cure insanity, barrenness, &c., to give rain, good crops, successful hunting, fishing, &c. The lowest form of F. is seen in what is also the first form of natural magic, when every man has his own amulet to protect him from all harm, and grant him all the success he desires in his occupations, being thus, at the same time, his own priest. Then family or household fetiches (teraphim, lares, &c.) are adopted, and the head of the house is the priest; or if wealthy, like Micah, 'the man of Mount Ephraim' (Judges xvii.), keeps a private chaplain. One step farther gives fetiches for the tribe, and a regular priesthood—medicine-men, rain-makers, jugglers, &c. The transition stage from F. to Polytheism is seen in the religion of the ancient Egyptians, with their unbounded use of amulets, and also their adoration of animals, or human forms with animals' heads, which were symbols of different attributes of deity. F. is systematised in the Shamanism (q. v.) of Tartary, and the Lamaism (q. v.) of Tibet and Mongolia. See MAGIC; also De Brosses's *Culte des Dieux fetiches* (1760); Pritchard's *Phys. Hist. of Mankind* (Lond. 1841); Catlin's *Letters, &c., on the N. American Indians* (New York, 1841); Theo. Parker's *Discourse of Religion* (*Works*, vol. i. Lond. 1866).

Fe'tid Lime'stone, called by the Germans *stinkstein*, is the name given to certain kinds of limestone, which, when struck with a hammer, emit a fetid odour, like that of sulphuretted

hydrogen—a result probably of the decomposition of animal matter. In the carboniferous limestones of Ireland, such rocks are of frequent occurrence.

Fet'lock, or **Fett'erlock**, was at first probably an instrument fastened to a horse's leg to hinder his escape. In heraldry it is represented by a short rounded bar, to which a semicircular steel band or chain is fixed.

Feu (Low Lat. *feudum*, lit. 'land held on feudal tenure,' from the same root as *fee*, *i.e.*, Old Eng. *feoh*, 'cattle,' 'goods'), a term of Scotch law denoting a sale of land for a stipulated annual payment, called the *F.-duty*. The deed of conveyance is called a *F.-contract* or a *F.-charter*, there being some legal difference as to the mode of enforcing the two. The F.-contract, like other titles to land, has been simplified by the Titles to Land Act of 1858. A F.-duty is heritable, but an arrear is movable. It is a *Debitum Fundi* (q. v.), and in addition to his personal action, in the event of non-payment the superior may *poind* the ground. (See POINDING.) He has also a real right in the land, and consequently a preference over purchasers and creditors. He has also a *hypothec* (lien) over the crop for the last or current F.-duty. Sometimes the stipulation is for payment in grain, in which case the quantity agreed on is valued according to the *Fiar* (q. v.) prices of the year, and the payment is made in money accordingly. But most modern feus are payable in money. Proprietors of land in Scotland near towns, manufacturing villages, or places of summer resort, are generally glad to add to their income by feuing ground for building purposes. F.-duties, being usually a very safe investment, bring a high price in the market, usually from twenty-two to twenty-three years' purchase, thus yielding a return of about 4½ per cent. The system of building on F. tenure possesses considerable advantages over the English system of long leases. The tenure being perpetual, the holder is probably led to erect more substantial buildings than he would otherwise do, and Scotch houses are accordingly remarkable for durability and warmth. There is another kind of F.-duty called a *Ground Annual* (q. v.). For England see GROUND RENT.

Feud (Old Eng. *faehdth*, 'enmity,' 'deadly quarrel,' from *fian*, 'to hate;' *cf.* Frisic *faithe*, Dutch *veede*, Ger. *fehde*, Dan. *fejde*) was at first the war waged by the kindred of a murdered man to revenge his death, and then was applied to any strife between different clans or families, in the times before private disputes were settled by law. The word has no connection with 'feudal' or 'feudalism.'

Feu'dalism (for derivation see FEU), the principle of holding lands by military tenure which prevailed during the middle ages. The Roman republic granted land to be held by military service, the holder being subject to the state; and after the Goths seized the Roman empire this Roman custom was united with the Gothic custom of devotion to a personal chief, and men received lands from their kings and leaders on condition that they gave their services in war. Land thus granted by a Gothic king was called a *feudum* or *fief*, and was held by *feudal* tenure; while lands which were not held of any lord were said to be held by *allodial* tenure, *allodial* being either the Latinised form of the Teutonic *odal*, 'noble' (*cf.* Mod. Ger. *adel*), or a derivative from the Teutonic *loos*, 'a lot.' Besides feudal and allodial tenures, there was a feudal relation called *commendation*, which Hallam compares to the Roman relation of patron and client, and by which a vassal promised military service in return for the protection of a powerful lord. The great chiefs, who admitted only a very slight supremacy on the part of the king, bestowed parts of their lands as fiefs, also on condition of military service, and these fiefs or benefices were again divided in subinfeudations. Gradually all the land in several countries was held by feudal tenure, but there never was a definite organised *feudal system*. 'Every one,' says Mr. Freeman (*Essays*, 2d series), 'should be on his guard against believing that any such thing as a "feudal system" ever existed anywhere.' F., instead of being imposed as a uniform *system* upon the several European countries, grew up slowly and with great modifications in different lands, according to their previous history and the character of their inhabitants, and in no country was it largely developed before the 10th c. It was at first understood that the king could at will resume the great fiefs, but these were soon regarded as life-holdings; and after Karl the Bald, by the Diet of Chiersi in 877, gave his *leudes* or chief vassals hereditary possession of their benefices, allodial tenures lost their importance, and gradually changed into feudal fiefs, the protection of a strong over-lord being preferable to the perilous independence of an allodial landholder. Before the end of the 11th c. most allodial tenures were extinct, except in the S. of France. There was no clearly recognised hierarchy of landholders, but each feudal country may be said roughly to have been held by the king, the great vassals, and then the lords, barons, and lower vassals. The king was nominally lord of the whole country, but had a very lax control over his great feudatories, his real power being generally limited to his particular territories, which were granted to smaller holders in the same manner as were the fiefs of the great nobles. It was at one time held that the vassals of a feudal lord were not the 'men' of the king, but simply the 'men' of their over-lord, and that if an over-lord warred against the king, his vassals could support him without being guilty of treason. These doctrines were in great measure the cause of the temporary breaking up of the French monarchy, and of the prolonged disintegration of Germany. One man became the vassal of another by paying *homage* (Lat. *homo*, 'a man'), which consisted in his placing his hands in those of his lord and swearing to be his 'man,' and to aid him in war. The principal obligations of a vassal were *service in war*, each feudatory being bound to serve forty days, or if he were a *homo ligeus*—*i.e.*, bound by a special arrangement—till the end of the war; *justitia*, the necessity of appearing to judge or be judged at his lord's court, a duty which, however, was generally discharged by proxy; *auxilia*, the obligation of paying sums when his lord had to be ransomed or went on a crusade, and when his lord's eldest or only son was knighted, or his daughter married. When the heir of a fief was a minor, the lord-superior was his guardian. If the ward was a female, the over-lord could propose a husband to her; and if she refused the suitor, she had to pay her feudal suzerain as much as any one would give him for the right of marrying her. The over-lord was also entitled to payments from his vassals on their inheriting lands, or on the alienating of a fief, but this seldom happened, as the right of alienation was a privilege opposed to the spirit of F. which was only slowly won by the humbler vassals. The relation of vassal and superior could be severed by the ending of the superior's line, or by the violation of the feudal oath taken when the vassal did *homage*. When women held fiefs, they had to find substitutes to perform military service. From the 4th to the 10th c. the clergy were looked on as a privileged class, and were free from any feudal burdens, but after the 10th c. they were made liable to military service for their estates, unless they purchased immunity, or held their lands by *frank almoigne*, *i.e.*, by saying masses for their superior's family. As the churchmen were often unable to guard their possessions, they generally obtained the protection of a noble, called their *advocate*, who was recompensed by lands or money. After the Church became feudalised, the clergy, as holders of fiefs, were considered to be the king's vassals; and as the Pope maintained that they were independent of the monarchy, struggles arose on this point between the regal and papal powers. Beneath the feudal landlords, lay or clerical, were the *villeins* and serfs, the original inhabitants of the countries conquered by the Gothic tribes. The *villeins* (Lat. *villanus*, 'one belonging to a *villa* or district') were small farmers bound to the soil (*ascripti glebæ*), who paid heavy rents, and could not leave the estates in which their farms lay. The serfs were miserable slaves, who had no common country, and almost no communication with each other, having no connections beyond their lord's territory. Towards these villeins and serfs a feudal chief stood in a different relation from that borne by the head of a clan towards his followers, the chief of a clan having a common lineage and common traditions with his dependants, while the feudal ruler and his inferior tenantry and serfs were quite alien from each other. F. varied greatly in different countries, some being far more thoroughly feudalised than others. Thus in France it was ruled that the eldest son should inherit all his father's lands, while in Germany fiefs were generally divided among all the last holder's male offspring. In France there were soon very few allodial tenures, while small freeholders were long numerous in Germany. The French fiefs early became hereditary, but it was not till the reign of Heinrich II. (1002-24) that the great German nobles were allowed to transmit their lands to their

children. In Germany, partly from fear of invasion, considerable power was at first intrusted to the kings, who in the 9th and 10th centuries were actual rulers, while the contemporary French monarchs had only a nominal superiority. The German vassals were at first less independent than the French, but after the German monarchy became elective, the regal power sank in Germany, while it rose steadily in France. The decline of the kingly power and the continued existence of small fiefs made F. endure longer in Germany than in any other country. In the N. of France, where there was no regular law after the breaking up of the Roman empire, F. was early and fully developed, while in the S. of France it was greatly modified by Roman law and a riper and fairer civilisation. France N. of the Loire was called *Pays du droit coutoumier*, 'the land of customary law;' France S. of the Loire, in which F. was only firmly established in the beginning of the 13th c., after the Albigensian crusade, being styled *Pays du droit écrit*, 'the land of the written or Roman law.' In the 10th c. there were in France 70,000 separate fiefs, of which 300 gave titles to their holders, and many were almost independent states, their rulers levying taxes, legislating, and administering justice at their own will.

The beginnings of F. in England can be traced before the Conquest. The thegns held lands from the king by military service, and practised subinfeudation before the reign of William the Conqueror, who, however, greatly strengthened the custom of holding land by feudal tenure from the crown, while he checked the growth of F. as a system of government, and withstood its tendency to break up a kingdom. He prevented it from developing as it did in France by retaining the old English legislative, judicial, and administrative constitution; by preserving the courts of the shire and hundred, which were open to all freemen, but were subject to the decisions of the royal judicial assembly. In the 12th c. the royal power was far stronger in England than it was in France; and F. was also weakened in England by the national council, by the great mass of freemen, who neither ranked with the Norman nobles nor had lost their lands and sunk into villeinage, by the nobles' estates being smaller and more scattered than those in France, and by the fact that most of the English estates were granted as rewards to his followers by William, whereas in France the great nobles had held their lands before the accession of Hugo Capet. The English nobles never had the rights of private war and of coining, and being far feebler than the Continental lords, leagued with the people against the crown. F. in England came to an end after the Wars of the Roses, in which many of the old nobility perished. F. was brought into Italy in the time of the Karlings, but was unsuited to the genius of the people. F. in Italy was always an exotic, which faded with the rise of the commonwealths, and had greatly vanished before the close of the 12th c., though feudal rulers shone with a transient brilliancy in the N. and S. of the land. Feudal tenures were introduced into Spain at a very late date, and, except in Aragon, had no strong effect on Spain. Neither did F. leave any impress on Hungary or on the N. of Europe. Feudal principles did not prevail wherever the feudal form was found. The kingly power, the Church, and the cities, though they seemed to conform to F., were always its foes at heart, and clung to the monarchic, ecclesiastic, and democratic principles. As the kingly power gradually rose and leagued itself with the communes, as Roman law was restored, as the universities brought together men from different countries and broke down the old severance of nation from nation, F. gradually died away. It was greatly weakened in the 12th and 13th centuries by the battles of Mansourah, Courtrai, Crecy, and Poitiers, in all of which the French nobles were severely defeated. Money payments (*escuages*) began to be taken instead of military service; wider ideas were introduced by the crusades; the strength of the great feudatories was sapped by their mutual strifes; a new mode of warfare was necessitated by the use of gunpowder; the superiority of infantry to feudal cavalry was finally proved by the battles of Agincourt, Granson, and Morat; and before the end of the 15th c. F., as a system of government, had well-nigh disappeared. 'F.,' says Guizot, 'is perhaps the only tyranny which men have never been willing to endure. They have willingly yielded to monarchic and theocratic despotisms; to F., never.' F. seems to have been at first almost indispensable for restoring something of social order to Europe; but it established no legal bonds, no political rights; it isolated man from man, and nation from nation, fostered private strifes, and ruined national unity and patriotic feeling. It transferred the governing power in great measure from the towns to the country, being intensely opposed to the spirit of civic life, and substituting personal for political relations. It only admitted the right of individual resistance in the case of the nobles, and offered no recognised place of appeal to such as could not redress themselves by force. Though a kind of rude federative principle ran through F., it was impossible to carry it into effect, the seignorial courts being very seldom held and of very slight influence. In its infancy it served to check invasion, and restored a harsh iron order in the place of chaos; while from the feudal lord being almost cut off from society, it gave a new importance to family life, and consequently improved the social position of women. See Guizot's *Hist. de la Civilisation en l'Europe*, and Hallam's *Middle Ages*.

Feu-de-Joie (Fr. 'joy-fire') is strictly a fire lighted in the streets or public squares on occasions of general rejoicing—a bonfire. The English use of the term is to denote a 'running fire' of musketry, when troops in line fire rapidly in succession, beginning from the right-hand man of the line, so that the effect is an uninterrupted, rolling discharge. The F.-de-J. is fired in commemoration of victories, in honour of distinguished persons, &c.

Feu'erbach, Paul Johann Anselm von, born at Jena, 14th November 1775, devoted himself to the study of positive law, on which he lectured at Jena. In 1798 he published his *Anti-Hobbes* (on the limits of the civil power) and his *Untersuchungen über das Verbrechen des Hochverraths.* He soon became the head of the 'Rigorist' school, who maintain that in the administration of criminal law nothing should be left to the discretion of the judge. The importance of this position is very great, for nothing shakes the authority of law more than manifest inequality of punishment. Hence the attempts made in countries without codes to codify the penal law. On the other hand it is maintained that within certain limits the discretion of the judge may give effect to circumstances which the law cannot well define beforehand. The danger of the Rigorist principle is especially seen in the case of cumulative punishments for a series of offences. The chief work of F.'s life was the drafting of the Bavarian Penal Code of 1813, for which he had prepared himself by his *Revision der Grundsätze und Grundbegriffe des peinlichen Rechts* (Erf. 2 vols. 1799), and his *Lehrbuch des gemeinen in Deutschland geltenden peinlichen Rechts* (Giess. 1801; 14th ed. 1847). This code modified those of Saxony, Hanover, Würtemberg, and of four of the Swiss cantons. F. died at Frankfurt, 29th May 1833. His best-known book is the collection of *Merkwürdige Criminalfälle* (Giess. 2 vols. 1808–11), translated into English by Lady Duff Gordon, in which he explains and criticises the system of seclusion and mental torture by which the law endeavoured to extract a confession from prisoners, even after conviction on circumstantial evidence, for the purpose of justifying the infliction of capital punishment. F. had several sons, who became distinguished in archæology, law, Oriental science, and mathematics. See *Leben und Wirken Ans. von F.'s* (2 vols. Leips. 1852), edited by his son.—**Ludwig Andreas F.**, son of the preceding, was born at Landshut, 28th July 1804. Under the theological and philosophical influences of Paulus at Heidelberg and Hegel at Berlin, he soon went further than his masters from the orthodox schemes of thought. Schleiermacher had analysed emotional religion into a feeling of complete dependence on the universe of God. F., not content with demolishing the modes of thought which rest on sacrifice and prayer, attacks this feeling of dependence so far as it implies anything beyond the calculated result of human work, invention, culture. God is what man wishes to become. If he looks to God for what he wishes to get apart from his own striving, he loses the only true religion. The religion which consists in wishing, and trusting to an invisible power, is a perversion of human nature.. Hence F. looks with disgust on the lamentations of Christians over their sins, on the privations of monastic life, on self-sacrifice for its own sake, and that wisdom of the cross which is opposed to the wisdom of the flesh. His chief work, *Das Wesen des Christenthums* (1841; Eng. trans. by George Eliot, 1871), is defiant and extravagant in its tone. Of his other works, the most notable are his *Theogonie* (2d ed. 1866), and his *Gott, Freiheit, und*

hydrogen—a result probably of the decomposition of animal matter. In the carboniferous limestones of Ireland, such rocks are of frequent occurrence.

Fet'lock, or **Fett'erlock**, was at first probably an instrument fastened to a horse's leg to hinder his escape. In heraldry it is represented by a short rounded bar, to which a semicircular steel band or chain is fixed.

Feu (Low Lat. *feudum*, lit. 'land held on feudal tenure,' from the same root as *fee*, *i.e.*, Old Eng. *feoh*, 'cattle,' 'goods'), a term of Scotch law denoting a sale of land for a stipulated annual payment, called the *F.-duty*. The deed of conveyance is called a *F.-contract* or a *F.-charter*, there being some legal difference as to the mode of enforcing the two. The F.-contract, like other titles to land, has been simplified by the Titles to Land Act of 1858. A F.-duty is heritable, but an arrear is movable. It is a *Debitum Fundi* (q. v.), and in addition to his personal action, in the event of non-payment the superior may *poind* the ground. (See POINDING.) He has also a real right in the land, and consequently a preference over purchasers and creditors. He has also a *hypothec* (lien) over the crop for the last or current F.-duty. Sometimes the stipulation is for payment in grain, in which case the quantity agreed on is valued according to the *Fiar* (q. v.) prices of the year, and the payment is made in money accordingly. But most modern feus are payable in money. Proprietors of land in Scotland near towns, manufacturing villages, or places of summer resort, are generally glad to add to their income by feuing ground for building purposes. F.-duties, being usually a very safe investment, bring a high price in the market, usually from twenty-two to twenty-three years' purchase, thus yielding a return of about 4½ per cent. The system of building on F. tenure possesses considerable advantages over the English system of long leases. The tenure being perpetual, the holder is probably led to erect more substantial buildings than he would otherwise do, and Scotch houses are accordingly remarkable for durability and warmth. There is another kind of F.-duty called a *Ground Annual* (q. v.). For England see GROUND RENT.

Feud (Old Eng. *faehdth*, 'enmity,' 'deadly quarrel,' from *fian*, 'to hate;' *cf.* Frisic *faithe*, Dutch *veede*, Ger. *fehde*, Dan. *fejde*) was at first the war waged by the kindred of a murdered man to revenge his death, and then was applied to any strife between different clans or families, in the times before private disputes were settled by law. The word has no connection with 'feudal' or 'feudalism.'

Feu'dalism (for derivation see FEU), the principle of holding lands by military tenure which prevailed during the middle ages. The Roman republic granted land to be held by military service, the holder being subject to the state; and after the Goths seized the Roman empire this Roman custom was united with the Gothic custom of devotion to a personal chief, and men received lands from their kings and leaders on condition that they gave their services in war. Land thus granted by a Gothic king was called a *feudum* or *fief*, and was held by *feudal* tenure; while lands which were not held of any lord were said to be held by *allodial* tenure, *allodial* being either the Latinised form of the Teutonic *odal*, 'noble' (*cf.* Mod. Ger. *adel*), or a derivative from the Teutonic *loos*, 'a lot.' Besides feudal and allodial tenures, there was a feudal relation called *commendation*, which Hallam compares to the Roman relation of patron and client, and by which a vassal promised military service in return for the protection of a powerful lord. The great chiefs, who admitted only a very slight supremacy on the part of the king, bestowed parts of their lands as fiefs, also on condition of military service, and these fiefs or benefices were again divided in subinfeudations. Gradually all the land in several countries was held by feudal tenure, but there never was a definite organised *feudal system*. 'Every one,' says Mr. Freeman (*Essays*, 2d series), 'should be on his guard against believing that any such thing as a "feudal system" ever existed anywhere.' F., instead of being imposed as a uniform *system* upon the several European countries, grew up slowly and with great modifications in different lands, according to their previous history and the character of their inhabitants, and in no country was it largely developed before the 10th c. It was at first understood that the king could at will resume the great fiefs, but these were soon regarded as life-holdings; and after Karl the Bald, by the Diet of Chiersi in 877, gave his *leudes* or chief vassals hereditary possession of their benefices, allodial tenures lost their importance, and gradually changed into feudal fiefs, the protection of a strong over-lord being preferable to the perilous independence of an allodial landholder. Before the end of the 11th c. most allodial tenures were extinct, except in the S. of France. There was no clearly recognised hierarchy of landholders, but each feudal country may be said roughly to have been held by the king, the great vassals, and then the lords, barons, and lower vassals. The king was nominally lord of the whole country, but had a very lax control over his great feudatories, his real power being generally limited to his particular territories, which were granted to smaller holders in the same manner as were the fiefs of the great nobles. It was at one time held that the vassals of a feudal lord were not the 'men' of the king, but simply the 'men' of their over-lord, and that if an over-lord warred against the king, his vassals could support him without being guilty of treason. These doctrines were in great measure the cause of the temporary breaking up of the French monarchy, and of the prolonged disintegration of Germany. One man became the vassal of another by paying *homage* (Lat. *homo*, 'a man'), which consisted in his placing his hands in those of his lord and swearing to be his 'man,' and to aid him in war. The principal obligations of a vassal were *service in war*, each feudatory being bound to serve forty days, or if he were a *homo ligeus*—*i.e.*, bound by a special arrangement—till the end of the war; *justitia*, the necessity of appearing to judge or be judged at his lord's court, a duty which, however, was generally discharged by proxy; *auxilia*, the obligation of paying sums when his lord had to be ransomed or went on a crusade, and when his lord's eldest or only son was knighted, or his daughter married. When the heir of a fief was a minor, the lord-superior was his guardian. If the ward was a female, the over-lord could propose a husband to her; and if she refused the suitor, she had to pay her feudal suzerein as much as any one would give him for the right of marrying her. The over-lord was also entitled to payments from his vassals on their inheriting lands, or on the alienating of a fief, but this seldom happened, as the right of alienation was a privilege opposed to the spirit of F. which was only slowly won by the humbler vassals. The relation of vassal and superior could be severed by the ending of the superior's line, or by the violation of the feudal oath taken when the vassal did *homage*. When women held fiefs, they had to find substitutes to perform military service. From the 4th to the 10th c. the clergy were looked on as a privileged class, and were free from any feudal burdens, but after the 10th c. they were made liable to military service for their estates, unless they purchased immunity, or held their lands by *frank almoigne*, *i.e.*, by saying masses for their superior's family. As the churchmen were often unable to guard their possessions, they generally obtained the protection of a noble, called their *advocate*, who was recompensed by lands or money. After the Church became feudalised, the clergy, as holders of fiefs, were considered to be the king's vassals; and as the Pope maintained that they were independent of the monarchy, struggles arose on this point between the regal and papal powers. Beneath the feudal landlords, lay or clerical, were the *villeins* and serfs, the original inhabitants of the countries conquered by the Gothic tribes. The *villeins* (Lat. *villanus*, 'one belonging to a *villa* or district') were small farmers bound to the soil (*ascripti glebæ*), who paid heavy rents, and could not leave the estates in which their farms lay. The serfs were miserable slaves, who had no common country, and almost no communication with each other, having no connections beyond their lord's territory. Towards these villeins and serfs a feudal chief stood in a different relation from that borne by the head of a clan towards his followers, the chief of a clan having a common lineage and common traditions with his dependants, while the feudal ruler and his inferior tenantry and serfs were quite alien from each other. F. varied greatly in different countries, some being far more thoroughly feudalised than others. Thus in France it was ruled that the eldest son should inherit all his father's lands, while in Germany fiefs were generally divided among all the last holder's male offspring. In France there were soon very few allodial tenures, while small freeholders were long numerous in Germany. The French fiefs early became hereditary, but it was not till the reign of Heinrich II. (1002–24) that the great German nobles were allowed to transmit their lands to their

children. In Germany, partly from fear of invasion, considerable power was at first intrusted to the kings, who in the 9th and 10th centuries were actual rulers, while the contemporary French monarchs had only a nominal superiority. The German vassals were at first less independent than the French, but after the German monarchy became elective, the regal power sank in Germany, while it rose steadily in France. The decline of the kingly power and the continued existence of small fiefs made F. endure longer in Germany than in any other country. In the N. of France, where there was no regular law after the breaking up of the Roman empire, F. was early and fully developed, while in the S. of France it was greatly modified by Roman law and a riper and fairer civilisation. France N. of the Loire was called *Pays du droit coutoumier*, 'the land of customary law;' France S. of the Loire, in which F. was only firmly established in the beginning of the 13th c., after the Albigensian crusade, being styled *Pays du droit écrit*, 'the land of the written or Roman law.' In the 10th c. there were in France 70,000 separate fiefs, of which 300 gave titles to their holders, and many were almost independent states, their rulers levying taxes, legislating, and administering justice at their own will.

The beginnings of F. in England can be traced before the Conquest. The thegns held lands from the king by military service, and practised subinfeudation before the reign of William the Conqueror, who, however, greatly strengthened the custom of holding land by feudal tenure from the crown, while he checked the growth of F. as a system of government, and withstood its tendency to break up a kingdom. He prevented it from developing as it did in France by retaining the old English legislative, judicial, and administrative constitution; by preserving the courts of the shire and hundred, which were open to all freemen, but were subject to the decisions of the royal judicial assembly. In the 12th c. the royal power was far stronger in England than it was in France; and F. was also weakened in England by the national council, by the great mass of freemen, who neither ranked with the Norman nobles nor had lost their lands and sunk into villeinage, by the nobles' estates being smaller and more scattered than those in France, and by the fact that most of the English estates were granted as rewards to his followers by William, whereas in France the great nobles had held their lands before the accession of Hugo Capet. The English nobles never had the rights of private war and of coining, and being far feebler than the Continental lords, leagued with the people against the crown. F. in England came to an end after the Wars of the Roses, in which many of the old nobility perished. F. was brought into Italy in the time of the Karlings, but was unsuited to the genius of the people. F. in Italy was always an exotic, which faded with the rise of the commonwealths, and had greatly vanished before the close of the 12th c., though feudal rulers shone with a transient brilliancy in the N. and S. of the land. Feudal tenures were introduced into Spain at a very late date, and, except in Aragon, had no strong effect on Spain. Neither did F. leave any impress on Hungary or on the N. of Europe. Feudal principles did not prevail wherever the feudal form was found. The kingly power, the Church, and the cities, though they seemed to conform to F., were always its foes at heart, and clung to the monarchic, ecclesiastic, and democratic principles. As the kingly power gradually rose and leagued itself with the communes, as Roman law was restored, as the universities brought together men from different countries and broke down the old severance of nation from nation, F. gradually died away. It was greatly weakened in the 12th and 13th centuries by the battles of Mansourah, Courtrai, Crecy, and Poitiers, in all of which the French nobles were severely defeated. Money payments (*escuages*) began to be taken instead of military service; wider ideas were introduced by the crusades; the strength of the great feudatories was sapped by their mutual strifes; a new mode of warfare was necessitated by the use of gunpowder; the superiority of infantry to feudal cavalry was finally proved by the battles of Agincourt, Granson, and Morat; and before the end of the 15th c. F., as a system of government, had well-nigh disappeared. 'F.,' says Guizot, 'is perhaps the only tyranny which men have never been willing to endure. They have willingly yielded to monarchic and theocratic despotisms; to F., never.' F. seems to have been at first almost indispensable for restoring something of social order to Europe; but it established no legal bonds, no political rights; it isolated man from man, and nation from nation, fostered private strifes, and ruined national unity and patriotic feeling. It transferred the governing power in great measure from the towns to the country, being intensely opposed to the spirit of civic life, and substituting personal for political relations. It only admitted the right of individual resistance in the case of the nobles, and offered no recognised place of appeal to such as could not redress themselves by force. Though a kind of rude federative principle ran through F., it was impossible to carry it into effect, the seignorial courts being very seldom held and of very slight influence. In its infancy it served to check invasion, and restored a harsh iron order in the place of chaos; while from the feudal lord being almost cut off from society, it gave a new importance to family life, and consequently improved the social position of women. See Guizot's *Hist. de la Civilisation en l'Europe*, and Hallam's *Middle Ages*.

Feu-de-Joie (Fr. 'joy-fire') is strictly a fire lighted in the streets or public squares on occasions of general rejoicing—a bonfire. The English use of the term is to denote a 'running fire' of musketry, when troops in line fire rapidly in succession, beginning from the right-hand man of the line, so that the effect is an uninterrupted, rolling discharge. The F.-de-J. is fired in commemoration of victories, in honour of distinguished persons, &c.

Feu'erbach, Paul Johann Anselm von, born at Jena, 14th November 1775, devoted himself to the study of positive law, on which he lectured at Jena. In 1798 he published his *Anti-Hobbes* (on the limits of the civil power) and his *Untersuchungen über das Verbrechen des Hochverraths*. He soon became the head of the 'Rigorist' school, who maintain that in the administration of criminal law nothing should be left to the discretion of the judge. The importance of this position is very great, for nothing shakes the authority of law more than manifest inequality of punishment. Hence the attempts made in countries without codes to codify the penal law. On the other hand it is maintained that within certain limits the discretion of the judge may give effect to circumstances which the law cannot well define beforehand. The danger of the Rigorist principle is especially seen in the case of cumulative punishments for a series of offences. The chief work of F.'s life was the drafting of the Bavarian Penal Code of 1813, for which he had prepared himself by his *Revision der Grundsätze und Grundbegriffe des peinlichen Rechts* (Erf. 2 vols. 1799), and his *Lehrbuch des gemeinen in Deutschland geltenden peinlichen Rechts* (Giess. 1801; 14th ed. 1847). This code modified those of Saxony, Hanover, Würtemberg, and of four of the Swiss cantons. F. died at Frankfurt, 29th May 1833. His best-known book is the collection of *Merkwürdige Criminalfälle* (Giess. 2 vols. 1808–11), translated into English by Lady Duff Gordon, in which he explains and criticises the system of seclusion and mental torture by which the law endeavoured to extract a confession from prisoners, even after conviction on circumstantial evidence, for the purpose of justifying the infliction of capital punishment. F. had several sons, who became distinguished in archæology, law, Oriental science, and mathematics. See *Leben und Wirken Ans. von F.'s* (2 vols. Leips. 1852), edited by his son.—**Ludwig Andreas F.**, son of the preceding, was born at Landshut, 28th July 1804. Under the theological and philosophical influences of Paulus at Heidelberg and Hegel at Berlin, he soon went further than his masters from the orthodox schemes of thought. Schleiermacher had analysed emotional religion into a feeling of complete dependence on the universe of God. F., not content with demolishing the modes of thought which rest on sacrifice and prayer, attacks this feeling of dependence so far as it implies anything beyond the calculated result of human work, invention, culture. God is what man wishes to become. If he looks to God for what he wishes to get apart from his own striving, he loses the only true religion. The religion which consists in wishing, and trusting to an invisible power, is a perversion of human nature. Hence F. looks with disgust on the lamentations of Christians over their sins, on the privations of monastic life, on self-sacrifice for its own sake, and that wisdom of the cross which is opposed to the wisdom of the flesh. His chief work, *Das Wesen des Christenthums* (1841; Eng. trans. by George Eliot, 1871), is defiant and extravagant in its tone. Of his other works, the most notable are his *Theogonie* (2d ed. 1866), and his *Gott, Freiheit, und*

Unsterblichkeit (1866). A collection of his works in 9 vols. appeared at Leipsic, 1845-57. He died at Nürnberg, Sept. 13, 1872.

Feuill'ans, the name of a reformed brotherhood of Cistercians founded in 1577 by Jean de la Barrière. The monastery of the order in the Rue St. Honoré, Paris, gave its name during the Revolution to a political club founded in 1790 by Lafayette, Siéyes, La Rochefoucauld, &c., who at first named their association the 'Society of 1789,' but afterwards, from the circumstance of their holding their meetings in the monastery of the F., were named F. The club advocated moderate and constitutional opinions in opposition to the Jacobins; but the latter rising in popular favour, the former came to be regarded with suspicion, and on the 28th March the club was violently suppressed by the populace.

Feuill'et, Octave, a French novelist, was born at St. Lô in Manche, 11th August 1812. He was educated at the college of Louis-le-Grand in Paris, and appeared for the first time as a writer in the columns of the *National* (1845). Since then he has sent forth an incredible number of tales, of which the best known are *Rédemption* (1849), *Bellah* (1850), *Le Cheveu Blanc* (1853), *La Petite Comtesse* (1856), *Le Roman d'un Jeune Homme Pauvre* (1858), *Histoire de Sibylle* (1862), *M. de Camors* (1867), and *Un Mariage dans le Monde* (1875). These are mainly distinguished by skilfully entangled plot, somewhat ambiguous morality, richly poetical descriptions, and lively satiric sketches of Paris society, not omitting its undercurrent of intrigue. F. is also the author of many successful comedies. In 1862 he was made a member of the Academy in place of Eugène Scribe, and in the following year officer of the Legion of Honour.

Feuille'ton (Fr. 'leaflet'), properly a portion of a political journal reserved for non-political matters, consisting generally of articles of criticism, light literature, art, belles-lettres, &c., usually printed in smaller characters at the bottom of the page, and separated from the matter above by a line. This system of publication was introduced by the *Journal des Débats*, and soon became highly popular. The *roman-F.*, a fiction published in this way, has extended from France to England, Germany, and America. The writer of such articles is a *feuilletoniste*.

Feve'da, an island of British Columbia, in the Gulf of Georgia, between Vancouver Island and the mainland. It is 32 miles long by 2 broad, and is valuable principally for its coal.

Fe'ver (Lat. *febris*, from *ferveo*, 'I grow warm,' or from *februo*, 'I cleanse') has been defined as a complex morbid state which accompanies many diseases as part of their phenomena, more or less constantly and regularly, but variously modified by the specific nature of the disease which it accompanies. The recognised characteristics of F. are those which relate either to the disintegration of the living substance of the body, or to the increase and diminished constancy of the bodily temperature. F. is both a state and a process, and has its beginning in the entrance into, or action on, the organism of some affecting or infecting cause. This event is followed by a period of latency, after which the first indications within the affected or infected organism begin to manifest themselves; but the F. process may vary indefinitely in its course, in its duration, and in the local inflammations which accompany it. In all cases, however, F. has its onset, accession, and declension, the onset being characterised by shivering, accompanied with rise of temperature of the internal parts of the body; the accession, by continued pyrexia and exhausting disorder of the bodily functions; the declension, epicrisis, or defervescence, by the restoration of these processes to their normal conditions and relations. Regarding the nature of F. and its relation to the febrile process, there are two possibilities, one being that F. originates in disorder of the nervous centres, and that by means of the influence of the nervous system on the systemic functions, the liberation of heat at the surface of the body is controlled or restrained, so that 'by retention' the temperature rises, and the increased temperature acts on the living substance of the body and disorders its nutrition; the other being that F. originates in the living tissues, and is, from first to last, a disorder of protoplasm, all the systemic disturbances being secondary. The most recent investigations have led to the conclusion 'that no disorder of the systemic functions, or of the nervous centres which preside over them, is capable of inducing a state which can be identified with febrile pyrexia; but that it is possible for such a state to originate and persist in the organism after the influence of the central nervous system has been withdrawn from the tissues by the severance of the spinal cord.' The tissue-origin of F. may, therefore, be adopted as the basis on which to construct an explanation of the F. process. This F. process is the prelude or accompaniment of a great variety of diseases, accidents, and surgical operations, but the term is most commonly applied to specific fevers, such as typhus and typhoid F., scarlet F., intermittent and remittent F., yellow F., puerperal F., and dengue. Small-pox and measles, although not usually called fevers, are so in reality. There being no single disease to which the term is applicable, no mode of treatment can be laid down suitable to every case of F. The treatment of F. will, therefore, be considered under the separate forms of the disease referred to. Dr. J. Burdon Sanderson has recently produced a compendious statement of the knowledge which at present exists as to the nature of the process of F. See *Reports of the Medical Officer of the Privy Council and Local Government Board*, new series, No. vi.

Fe'verfew (*Pyrethrum parthenium*), a genus of Composite plants, common in our gardens, and deriving its name from having long been employed as a popular remedy in ague and other fevers, and as an emmenagogue. It appears to possess stimulant and tonic properties. F. is a perennial plant, and may attain a height of 1 or 2 feet. Its leaves are flat and broad, its flowers small. It is nearly allied to Camomile (q. v.). The variety grown in gardens is generally of double nature. The Mayweed (*P. inodoratum*) has larger flowers with white ray and yellow disc florets. It is common in cornfields and hedgerows.

Fe'verwort (*Triosteum perfoliatum*), a genus of plants included in the natural order *Caprifoliaceæ*. They are found in N. America, where, under the name of Tinkar's Root (from Dr. Tinkar), they have been long employed as emetics and purgatives. The berries are also used as a substitute for coffee. The F. has an erect rounded stem, opposite leaves, axillary whorls of flowers, a tubular corolla, and three-seeded berries.

Fez, or properly **Fês** (Arab. 'the fertile'), one of the capitals of Morocco, is picturesquely situated in the valley of the Sebu, 100 miles inland from its port, Mehedia. It is the Rome of the Western Arabs, and has, it is said, 360 mosques, of which the chief is the *El Karubin*—an inviolable sanctuary even for criminals of the deepest dye. There are several public schools, and a university, besides the sultan's palace, and numerous bazaars, caravanserais, baths, &c. The town walls are in great disrepair. F. is the centre of an active caravan trade reaching to Mecca in the E., and to Timbuctu in the S., and has manufactures of Beduin mantles, morocco leather, linen, fine tapestry, jewellery, carpets, silks, slippers, and F. caps. Pop. estimated at about 150,000, mostly Moors, Beduins, Berbers, Jews, and Negroes. F. was founded by Edris II. in 808 A.D., and was one of the largest and richest cities of the Mohammedan world in the middle ages.—The *province* of F., the most northerly in Morocco, was formerly an independent state. Area, 117,725 sq. miles; pop. 3,200,000.

Fezzan' (anc. *Phazania*), a great oasis of N. Africa, and the most southerly province of Tripoli, stretches from the springs of Meshru to the town of Bondshem, a distance of 350 miles. Area, 25,000 sq. miles; pop. 26,000, mostly Berbers and Beduins. It is traversed in the N.E. by two parallel ranges—the Black and White Mountains; and in the S. the fertility of its wadies, which yield wheat, maize, barley, &c., gives way to the burning sands of the Sahara. The climate is very unhealthy, the summer temperature frequently reaching 133° F. Journeys are performed on the camel or horse, and the plateaus are infested with the wild animals and birds of the great waste. Murzuk is the capital (pop. 4000), and there are many small towns and villages. The natives resemble negroes in colour, but are of Berber family, and speak a mixed Berber and Arabic language. See Barth's *Travels in Central Africa* (Lond. 1857).

Fi'ars (Fr. *feurs*, 'money for tillage,' or Icel. *fe, fiar*, 'money'), in Scotch law, are the prices of grain in the different counties fixed by their respective sheriffs, in February each year, with the assistance of juries. The form of striking the F. is prescribed by Acts of Sederunt of the Court of Session. They regulate the prices of all grain stipulated to be sold at fiar prices.

They also regulate the price in contracts concerning grain to be delivered, and in cases in which no price has been agreed to between parties. Results are arrived at by examining witnesses, whose testimony is digested by a skilled accountant. See *Historical Account of the Striking of the F. in Scotland*, by George Paterson, Esq., advocate (1852).

Fias'co, an Italian word (from Med. Lat. *flasco*, 'a flask,' but the reason for the derivation is unknown) applied to a failure generally, but originally an expression of frequenters of the theatre in Italy to mark a musical failure. The word has been introduced into France, Germany, and England.

Fi'at (Lat. 'let it be done'), a legal term for an order or warrant for the doing of an act. It was a term till lately of frequent use in the law of England under the Bankruptcy Act. But the term now in use under the Act of 1869 is Adjudication (q. v.).

Fi'ber. See BEAVER and MUSQUASH.

Fi'bres. By F. in histology is meant a microscopical solid filament. There are various kinds of F. found in the body, namely, white fibrous tissue, elastic tissue, involuntary muscular fibre, voluntary muscular fibre, and nerve fibre. These will be found described under their respective headings.

Fibres, Tex'tile, are all substances, mineral, animal, and vegetable, employed to form cordage or woven into webs. This definition includes all metallic wires from which cordage or wire cloth is formed, although such are not usually regarded as T. F. Besides these metallic substances, asbestos or amianthus is a fibrous material derived from the mineral kingdom, which has occasionally been woven into a kind of cloth, and in recent years has been much used for engine packing, non-inflammable millboard, and such purposes. The ordinary T. F. of commerce are, however, entirely derived from animal and vegetable sources, and all those of any economic importance will be noticed under their proper headings. We here simply enumerate the principal fibrous materials.

Animal Fibres.—The chief T. F. of animal origin are Silk (q. v.) and the Wool (q. v.) of sheep, closely allied to which is the pashm, or fine wool of the Cashmir goat, and Mohair (q. v.). Camels yield a woolly hair much used for weaving and felting in Russia and Western Asia. To this family belong the Guanaco, Vicuña, and Alpaca (q. v.). The hair of several other animals, including the rabbit, the hare, the nutria, &c., is used for felting purposes. Horsehair must also be included among T. F., being used for the seating of chairs, sofas, &c.; and as a simple curiosity among animal fibres, the byssus of a mollusc (*Pinna squamosa*) deserves mention, as being occasionally woven into small articles.

Vegetable Fibres.—Of all vegetable fibres the most important is Cotton (q. v.), and next to it is Flax (q. v.). Following these comes Jute (q. v.), and for cordage specially, but also for weaving purposes, Hemp (q. v.). Esparto (q. v.) grass is now of extensive use in making paper. China grass, the beautiful fibre yielded by *Bœhmeria nivea*, has not yet won the prominence it deserves, from the difficulties connected with its preparation. Phormium fibre or New Zealand flax, derived from *Phormium tenax*, is highly useful, as is also Coir (q. v.), obtained from the outer husk of the cocoa-nut, and Manilla hemp, the produce of *Musa textilis*. The following are also of some importance—Sunn hemp from various species of *Crotalaria*, bowstring hemp from species of *Sanseviera*, aloe fibres from species of *Agave*, plantain fibres from species of *Musa*, lime-tree bast from *Tilia Europæa*. The fronds of several palm-trees also yield fibrous materials of considerable value for weaving, plaiting, and basket-making, and wheat straw and the stalks of many other grasses are employed for hat and mat making.

Fi'brin, Fibrin'ogen, Fibrinoplas'tic Sub'stance. In the coagulation of the blood a substance is formed known as F. At one time it was supposed to exist as such in the blood, but now it is known that it is formed by the union of two other matters, namely, fibrinogen and fibrinoplastic substance. See BLOOD, COAGULATION OF.

Fi'bro-Se'rous a term used in anatomy to denote certain membranes, such as the pericardium, which are double, being composed of a layer of fibrous tissue lined by a layer of endothelial cells constituting a serous coat.

Fich'te, Johann Gottlieb, a German metaphysician, was born at Rammenau, Upper Lusatia, on 19th May 1762, and studied theology at Jena. During a visit to Switzerland he made the acquaintance of Lavater and of Johanna Rahn, the niece of Klopstock. He then taught Greek and philosophy privately at Leipsic, and in 1792 went to Königsberg to see Kant, to whom he presented his *Kritik aller Offenbarung*. Its publication rescued F. from starvation, and gave him a chair of philosophy at Jena. Here he lectured with such intensity of moral enthusiasm and such original power of speculation that he was accused of atheism and had to resign. In 1799 he retired to Erlangen, where he occupied the chair which he afterwards filled at Berlin. To Jena belong his *Wissenschaftslehre* (1795) and *System der Sittenlehre* (1798); to Berlin his *Ueber die Bestimmungen des Menschen* (1800), and his *Reden an die Deutschen* (1808), a series of heroic addresses to the German people after the disasters of Jena and Auerstadt; to Erlangen his *Ueber das Wesen des Gelehrten* (1805), *Grundzüge des gegenwärtigen Zeitalters* (1805), and *Anweisung zum seligen Leben oder die Religionslehre* (1806). The political tragedies of the time gave immense significance to his words. In 1810 he was employed to reconstruct Berlin University, of which, although there was a crowd of the most distinguished scholars in the chairs, he was made rector. When Germany rose against Bonaparte after his fatal campaign in Russia, F. enrolled himself as a volunteer in 1813, but died 28th January 1814, from a fever caught while nursing his wife, Johanna Rahn.

As regards F.'s philosophical position, we must recollect there were already many modifications of Kantianism. Reinhold added a representative faculty. Sigismund Beck pointed out that the assumption of a *ding an sich* or *noumenon* was not consistent with the spirit of the critical system. Jacobi had advocated an intellectual intuition as a source of spiritual truth. Bardili had already effected a monistic analysis—thought is the ground of all, for the concept of possibility precedes the apprehension of reality. Schultze and Maimon had arrived at pure scepticism. F.'s heresy from Kant consisted in referring the non-ego, the objective element in knowledge, to the pure activity of the ego. Substance is merely a mental synthesis of accidents. Without the ego, then, there is no non-ego, no object, no world; and unless the ego be regarded as a spontaneous activity (*thathandlung*), you get the contradiction of A and not-A each requiring the other as its condition. Mankind are quite correct in attributing a real existence to objects, but the object is not independent of the subject, they are identical. On any system of dualism you must be content with a knowledge of phenomena; but admit the unity of existence, and your knowledge becomes certain. F. is, however, compelled to assume an underlying force different from the ego (*anstoss*) which originates all the reflective power and self-limitation of the ego. Perhaps this force is what he calls the 'reine Form der Ichheit, welche noch nicht Individuum ist'—an impersonal reason, like the 'divine mind' of Berkeley. Morality, or the perfect freedom and development of the ego, consists in the gradual assimilation of the non-ego which at first appears in opposition to the ego. Thus human virtue creates the world, it is the incarnation of duty. God is the infinite moral order, and is the subject of faith, not inference. F.'s philosophy of history is contained in his *Grundzüge des gegenwärtigen Zeitalters*. There he deduces *a priori* the world-plan from the general conception of time, which again yields the conceptions of particular epochs. It is quite possible that empirical history, or the facts of experience, may not square with the world-plan: there are 'foreign elements' of which the philosopher is not bound to give an account. This seems an admission of dualism. In the *Wissenschaftslehre* he states the end of life to be the ordering of human relations with freedom according to reason, human life being assumed to be a necessary part or development of divine life. The five epochs are the state of innocence and instinct; the age of authority, external institutions, dogmatic creeds, and progressive sin; the age of indifference to truth, and the complete rejection of the authority of reason, conscious or unconscious; the age of science, in which the laws of reason are clearly seen, and truth is revered for its own sake; the age of art, in which humanity becomes beautiful by its cultivated and enlightened freedom. In the *Reden*, when Berlin was in the hands of the French, he contends that the *Mischvolk* (or mixed Romance nations, like the French) are now exhausted, while the *Urvolk* (primitive or German nations) have the world's

future within them. F.'s *Sammtliche Werke* (8 vols. Berl. 1845-46) were edited by his son. See *F.'s Biography and Correspondence* (1830-31; 2d ed. 1862) by the same editor; Fischer's *Geschichte d. neuern Phil.* (vol. v. 1868); English translation of the *Wissenschaftslehre* by Kroeger, and of the *Popular Works* (with Memoir) by William Smith (1848).—**Immanuel Hermann F.**, son of the preceding, was born at Jena, July 18, 1797. He studied philology at Berlin, and was early devoted to history and philosophy. He spent his early life as a teacher, was made Professor of Philosophy at Bonn in 1836, and at Tübingen from 1842 to 1875. He died in 1876. His works, which are voluminous, include *Die speculative Theologie* (1846); *Grundzüge zur Entwickelung der künftigen deutschen Reichsverfassung; System der Ethik* (1850-53); *Anthropologie, neubegrundet auf naturwissenschaftlichem Wege* (1860); *Psychologie als Lehre vom bewussten Geiste des Menschen* (1864); *Fragen und Bedenken über die nächste Fortbildung deutscher Speculation* (vol. i. 1876). In philosophy F. was mainly a disciple of his father. He was strongly opposed to the Pantheistic doctrines of Hegel, against which he advocated what he called 'concrete theism,' maintaining the personality of God and the perfect dualism between God and the world. He held that the chief fact in the history of German philosophy was the contest between Theism and Pantheism; that the latter had been most ably developed by Hegel, who, however, had been refuted by Baader; that recent progressive German thought was represented by Krause, Weisse, and Lotze. Christianity, he believed, ought to become a great instrument of civil reform. He wrote several political pamphlets advocating moderate Liberalism and decrying revolution. His *Contributions to Mental Philosophy* have been translated by J. D. Morell (Lond. 1860).

Fici'no, Marsil'io, one of the leading scholars of the Renaissance, and one of the first who made Plato known to Western Europe, was born at Florence, October 19, 1433. His father was physician to Cosmo de Medici, who founded a Platonic school, of which he made F. the teacher. F. translated Plato and several of the Neo-Platonists, and lectured at Florence with shining success. His most distinguished pupils were Politiano and Lorenzo de Medici, the latter of whom gave him a canonry in Florence cathedral. He died at Careggi, October 1, 1499. Like his friend Mirandola, he sought to reconcile Platonic philosophy with Christianity, and developed a mystical theism enwoven with mediæval sentiment. Platonism, he held, was a foreshadowing and confirmation of Christianity, and he kept a lamp ever burning before the bust of Plato, as if it had been the image of a saint. He vastly aided the classical revival, while his fervent philosophy did much to counteract the immorality of the Church and the pagan licence favoured by many of the humanists. His works, of which the *Theologica Platonica* and the translation of Plato were issued at Venice in 1516, were published at Basel in 1491, 1576, and at Paris in 1641. See Corsi's *M. Ficini Vita*, written in 1506, but first published at Pisa by Bandini in 1772; and Symonds' *Renaissance in Italy* (Lond. 1875).

Fic'tion. See NOVELS.

Fiction of Law is a legal assumption that 'hat is true which is either untrue or is as probably false as true. The law of England has adopted fictions more largely than that of any other country, but to some extent all nations have done so, dreading, according to Dr. Colquhoun (*Summary of the Roman Civil Law*) 'to adopt any abrupt measure which might disturb the practice and effect of former decisions.' By this he means that it is often considered desirable, in making a substantial change, to keep pace with social progress, to preserve an ancient form, and to force the change and the form into apparent harmony by means of a fiction. Thus while social progress has made it necessary that power which formerly belonged to the crown in England should be transferred to the House of Commons, the dignity of the crown—and consequently the social sentiment which has gathered round the institution from historical association—is preserved by important acts being still done in the name of the sovereign. No doubt the social weight of royalty is preserved by this fiction, and a practical end desired by the people of England is thus attained. But where there is no sentiment in question, it is difficult to see the use of legal fiction. A father in England can only get an award of damage for the seduction of his daughter on the fiction that she was his servant, and that he has suffered pecuniary loss from being deprived of her services. The award of damage must either be commensurate with the fictitious ground, or if in excess of it, the fiction is absolutely of no effect.

Fi'cus. See FIG.

Fid, a square bar of iron or wood which forms the support of topmasts. It is passed through a hole at the heel of the topmast, and its extremities rest on the tressel-trees. The *splicing-F.* is a pin tapering to a point at one end and made with an eye at the other, used by sailors in opening the strands of ropes preparatory to *splicing*.

Fid'dle. See VIOLIN.

Fid'eicommiss'um, a term of Roman law denoting the position of an estate bequeathed to an heir with the condition that he should bequeath it to a third person mentioned, that third person being sometimes directed to pass it to a fourth person, and so on. When the practice of so bequeathing property was first introduced in ancient Rome, it was not sanctioned by the laws; performance of the condition therefore depended on the good faith of the heir; but in the reign of Augustus that monarch instructed the prætor to enforce these trust obligations. The condition of F. might be either particular or universal. If the former, it only applied to part of the inheritance; if the latter, it applied to the whole of it. Estates *fideicommissa* are the earliest instance which we find of entails. (See ENTAIL.) The authority given to the prætors by Augustus was by Clodius extended to the consuls and governors of the provinces. In German civil law the *fideicommiss* is the regulation according to which the whole or part of a family property goes to a certain member of the family conditionally on his leaving it to the person indicated by the family arrangement. In Holland also the principle of F. has important application in regulating succession to land.

Fidic'ula, a small lyre-shaped musical instrument.

Fief. See FEUDALISM.

Field, in heraldry, the ground or whole area of the shield, said by old writers to be so named because the charges upon it originally represented the great deeds done upon the field of battle.

Field, Cyrus West, was born at Stockbridge, Massachusetts, November 30, 1819, and rose by energy and perseverance to be the head of a large mercantile business. He travelled in South America, and later became deeply interested in ocean telegraphy. In 1854 he took up the idea of an Atlantic cable, founded the two great transatlantic telegraphic companies, and toiled incessantly till he saw the realisation of his hopes in 1866. (See TELEGRAPH, SUBMARINE.) In the course of this work he crossed the Atlantic some fifty times. He received many medals and honours, and has since been engaged in helping to establish telegraphic communication between Europe, India, China, Australia, and S. America.

Field Allow'ance, a compensation allowed to British officers for service in the field, in consideration of the extra expense which such service entails. When in camp in the United Kingdom or in the colonies, *ordinary* F. A. is made; when engaged in active service, *i.e.*, during a campaign, *extra* F. A. is made. *Ordinary* F. A. for a general is £1, 10s. a day, *extra* £2, 10s.; for a subaltern, 1s. and 1s. 6d. respectively.

Field Bug (*Pentatoma*), a genus of Hemipterous insects belonging to the Heteropterous section of the order. These insects occur in fields and amongst grass, and possess mouths adapted for biting and suction.

Fieldfare (*Turdus pilaris*), a species of British thrushes included in the Dentirostral section of the order *Insessores* (q. v.). The F. arrives in Britain in winter, and departs in May or June for N. Europe to breed and build. The upper parts of the birds are ashen grey; the head is marked with dark-brown spots. The back, wings, and tail are dark brown; the chin and throat of a golden hue, spotted with black; the breast reddish brown, and the belly white. The average length of the

F. is 10 inches. Its nest is made of sticks, grasses, and clay. The eggs number three, four, or five, and are of light brown colour, spotted with dark brown.

Field-Glass is the lens interposed between the object-glass and eye-glass of a compound Microscope (q. v.), to receive the rays diverging from the focus of the former, and thus to render the image magnified by the eye-glass of more convenient dimensions and of greater distinctness than would otherwise be the case.

Field'ing, Copley Vandyke, the most distinguished member of an English family of painters, was born in 1787. A painter in water-colours and a teacher of art, he spent a singularly peaceful and prosperous life, was elected President of the Old Society of Painters in Water-colours, and held the office till his death, at Worthing in Sussex, March 3, 1855. He is one of the greatest of English landscape painters, though his manual dexterity and reputation led him latterly to produce many conventional pictures. The ideas which in these had become stereotyped he had originally taken from nature. His happiest efforts are vapoury perspectives in the Weald of Sussex, stormy sea-pieces off the chalky Kentish coast, and leafy dens in Hampshire.

Fielding, Henry, a famous English novelist, was born at Sharpham Park, near Glastonbury, Somersetshire, April 22, 1707. His father was Lieutenant-General Edmund F., a cadet of the Denbigh family, and thus connected with the imperial house of Hapsburg. After an education at Eton, where Fox and Lyttelton were among his friends, F. in his eighteenth year was removed to Leyden University. There he remained for two years, studying civil law, until his father's poverty compelled him to leave Germany for London. In his own words, he had to turn 'either hackney writer or hackney coachman,' and so, choosing the former alternative, he began to write comedies and farces. His first play, *Love in Several Masques*, was acted at Drury in 1728. From that time onwards he produced a constant succession of dramatic pieces, composing no fewer than six in the one year 1733. In 1736 F. married Miss Craddock of Salisbury, and about the same time fell heir to an estate in Dorsetshire of £200 a year. His improvidence, however, soon wasted this small fortune, and in 1739 he had to take refuge again in London. He resumed his legal studies with great diligence, and was called to the bar in 1740, but being prevented from practising by repeated attacks of gout, he had to fall back once more on the theatre and literature. In 1742 appeared his first novel, *Joseph Andrews*, originally intended as a parody on Richardson's *Pamela*. About this time his wife, to whom he was tenderly attached, died, and shortly after F. braved the conventional by marrying her maid. His next published works were the *Journey from this World to the Next*, and *Jonathan Wild* (1743); but in 1748 the interest of Lord Lyttelton made F. independent of authorship, by procuring for him the police-magistracy of Middlesex and Westminster, which office he filled with much conscientiousness and credit. In the same year *Tom Jones* was published, and two years later *Amelia*. For the former of these works F. received £600, and for the latter £1000. The great novelist's health was by this time entirely ruined, and in July 1754 he resolved, as a last resource under his complication of diseases, to seek the warmer climate of Portugal. This, however, was of little avail; he died at Lisbon, October 8, 1754. F. is in some respects the greatest of English novelists. His inspiration was received from Richardson, but he is, far more than Richardson, the creator of the English novel. His power lies greatly in his intense yet artistic realism; and this charm is enduring, for he was not more conversant with the manners and feelings of his own time than with those feelings of humanity which are the same at all times. Hence it is that Byron calls him 'the prose Homer of human nature.' He had seen both high and low life, and reproduced both, but especially the latter, with consummate art. Many of his best-known personages are drawn from living models. The immortal 'Parson Adams' had for prototype the Rev. William Young; 'Mr. and Mrs. Booth' were Fielding and his wife—the latter appears also as 'Sophia Western;' 'Parson Trulliber' was F.'s tutor; and 'Squire Allworthy,' 'Blifil,' and 'Lord Fellamar,' all had representatives in real life. F.'s skill in the construction of a plot is not great, and one can only regard Coleridge's dictum that the '*Œdipus Tyrannus*, the *Alchemist*, and *Tom Jones* are the three most perfect plots ever planned,' as a profound hallucination. Yet F.'s fertility of invention was not lawless or digressive. There is a certain unity of design in all his work, and he excites interest without violating probability. Some of the finest features of his genius reappear in Thackeray. The masterpiece of F. is *Tom Jones*, a work of fiction unsurpassed for wealth of character, artistic construction, and easy grace of style. Despite occasional coarseness, its morality is on the whole healthy. Gibbon has called *Tom Jones* 'the first of ancient or modern romances,' and La Harpe 'le premier roman du monde.' *Amelia* has been styled the Odyssey to F.'s Iliad; it is less varied and interesting than *Tom Jones*, but the heroine is exquisitely drawn. *Joseph Andrews*, begun as a caricature in the style of Cervantes, ended by becoming a serious fiction, and contains the inimitable character of 'Parson Adams.' *Jonathan Wild*, the least of his novels, is wonderful as a piece of sustained irony. F.'s collected works were published at London in 4 vols. 1762, again in 10 vols. 1764, in 14 vols. 1808, and again in 1821 and 1851. See Murphy's Life, Sir W. Scott's Life, Lawrence's Life, Lady M. Wortley Montagu's *Letters*, Thackeray's *English Humourists*, and Jesse's *Celebrated Etonians*, vol. i.

Field-Marshal, the highest military rank in Britain and some other countries. The title is the same as the *maréchal de camp* of the old French army, and the *feldmarschall* of the German service. The F.-M. is saluted with the standards of all the forces except the Household Troops, who would pay him that honour only in the case of his being their colonel. In peace his pay is the same as that of any other general, but in war he receives £16, 8s. 9d. a day, or nearly double the pay of his generals.

Field-Mouse, Wood-Mouse, or **Long-Tailed Field-Mouse,** the subject of at least one charming poem, is regarded as a nuisance and a pest wherever it occurs. Somewhat larger than a common mouse in tail, ears, and muzzle, it differs from it also in being lighter in the colour of the under parts of its body. It occurs throughout all the temperate regions of Europe, and the ravages it commits in the fields and gardens may be estimated from the immense stores of grain and other food found in its storehouse among thick grass or in a hollow of the earth. Another species of F.-M. is the small harvest-mouse. See MOUSE.

Field-Officers are colonels, lieutenant-colonels, and majors, or such as may command battalions, and thus have charge of the field. They are always mounted in order to give ground for movements, circulate orders, &c.

Field of View is the space within which objects can be seen by a telescope or microscope which has been adjusted to its focus.

Field-Train is that department of the artillery intrusted with the charge and supply of stores and ammunition, and whose duty it is during an engagement to see that each gun is served with its full complement of men.

Field-Works are temporary fortifications, as trenches, ramparts, &c., constructed to cover an attacking, or protect an encamped force. See FORTIFICATION.

Fi'eri Fa'cias, a writ in English law for enforcing judgment against the goods of a debtor. If in execution the officer take the goods of a stranger, he is liable in damage. The writ cannot be enforced after a *Capias ad Satisfaciendum* (q. v.) has been issued. F. F. *de bonis ecclesiasticis* is a judicial writ directed to the bishop of a diocese, requiring him to attach the ecclesiastical goods of a clergyman within his diocese in satisfaction of judgment.

Fies'chi (sing. *Fiesco*), an ancient Italian family, Counts of Lavagna near Genoa, who are discernible in history as early as the 10th c. In the 12th c. we find them always quarrelling with the consuls and community of Genoa, of which, however, they finally became noble burgesses in 1198. The F. had possessions in Piedmont, Lombardy, Naples, Liguria, Umbria, and were owners of Massa and Cassara. The family produced two popes, Innocent IV. and Adrian V., thirty cardinals, more than 300 patriarchs, archbishops, and bishops, not to speak of soldiers and sailors. They were among the most zealous members of the Guelph faction. Few of them, however, possess much historical interest. We may note **Bartolomeo F.,** who flourished in the beginning of the 16th c. By an act of rudeness to a peasant he excited (1505) a revolution of the burgher and

artisan class, who then desired a share with the nobles in the government of the republic of Genoa. The result was that French troops, sent by Louis XII., took possession of the town. —**Giovanni Luigi F.**, born in 1523, distinguished himself by a conspiracy against the ruling house of Doria, which was assisted by Duke Farnese, and approved of by François I. The plot miscarried through the accidental drowning of its chief, as he passed on board one of the admiral's ships, January 2, 1547. Schiller has dramatised this subject.

Fieschi, Joseph, born in Corsica, December 3, 1790, served in Murat's army, and afterwards led an obscure life in France till 1835, when, having lost his place by the Government suppressing it, he resolved, along with Pepin and Morey, to attempt the murder of Louis Philippe on the anniversary of the Revolution (28th July). They contrived the 'infernal machine,' of twenty small cannons, which was fired from a house in the Temple Boulevard, killing eighteen persons and hurting F., but not touching the king. The conspirators were guillotined, February 16, 1836.

Fie'sole, a small Italian town in Tuscany, crowning a hill above the Arno, about 3 miles from Florence. It is the seat of an archbishop, and possesses an old cathedral. The Franciscan church rises far above the rest of the town, and marks the site of the ancient *arx* or citadel. Pop. about 2500. F., the ancient *Fæsulæ*, has been an important military station from very early times. It was one of the oldest Etruscan towns, but was never a large place, and has sunk with the rise of Florence. There are parts of a Roman theatre, and remains of cyclopean walls, built with huge quadrangular stones, at F.; and various ancient relics have been found. See Freeman's *Historical and Architectural Sketches* (1876).

Fiesole, Giovanni da. See Fra Angelico.

Fife, a kind of octave or piccolo flute, used in military 'drum and F.' bands. Its tone is shrill and piercing—inspiring, but hardly pleasant. It has not keys like the piccolo used in the orchestra, and its musical capacities are thus extremely limited.

Fife-Ness, the eastmost point of land in Fifeshire, 2 miles E. by N. of Crail. From F.-N. a dangerous ridge of rocks, known as the Carr Rocks, projects a considerable way into the sea. On this a beacon, 35 feet high, has been erected.

Fifeshire, an almost peninsular county in the E. of Scotland, bounded N. by the Firth of Tay, E. by the North Sea, S. by the Firth of Forth. Its greatest length is 44 miles, and its greatest breadth 18 miles. Area, 328,427 acres; pop. (1871) 160,735. The coast is rocky in the N. and N.E., and along the Forth is steep, often luxuriantly wooded, and studded with many thriving towns. In the N. there are low offshoots from the Ochils, separated by the strath of the Eden, or Howe ('hollow') of F., from the central range of the Lomonds, which rise in W. Lomond to 1713 feet. Largo Law, in the S., is 1020 feet high. The chief rivers are the Eden and Leven. The climate is somewhat bleak and damp in the N., but dry and mild in the S. F. is well cultivated, the richest district being a belt of loam from 1 mile to 3 miles broad, which fringes the Firth of Forth. The county is well wooded, much grain is produced, but the N.W. is mostly heathy upland and barren moor. In 1873, of the 242,502 acres under cultivation, 91,102 were under corn crops, 48,770 under green crops, 47,732 under permanent grasses, and 53,367 under grasses. The formation is chiefly carboniferous, interspersed with trap. Limestone and freestone are much quarried, and there are valuable coal and iron mines. The principal manufacture is linen, and the most important exports are coal, lime, and fish. The chief places are Cupar, the county town, St. Andrews, Kirkcaldy, Kinghorn, Dunfermline, E. and W. Anstruther, Burntisland, Crail, and Dysart. F., which returns one member to Parliament, was anciently the most flourishing region in Scotland. Its thanes seem to have been the most powerful of Scottish nobles before the 11th c. It was styled the 'Kingdom of F.,' but does not figure greatly in Scottish history until the Reformation struggles.

Fifteenth', in music, an interval of two octaves.

Fifth Monarchy Men, a small fanatical sect which arose in England about 1654. They were sometimes called Millenarians, and believed that a fifth monarchy was to succeed the four monarchies of Daniel's vision—the monarchy of Christ on earth, which was to 'stand for ever,' or to remain for 1000 years. They anticipated the immediate advent of the Messiah on earth, and declared that whatever was opposed to the establishment of Christ's kingdom must be assailed by true believers. These tenets led to their conspiring to murder Cromwell in 1657, but their plot was disclosed and their leaders were flung into prison. Shortly after the Restoration they rebelled in London under one Venner, but were promptly suppressed, and Venner and others were executed. Others of the sect were executed in 1662 on a charge of having conspired to murder Charles II. The people seem to have confounded them with the early Münster Anabaptists, and their excesses drew odium on the Baptists, Quakers, and Independents, who had no connection with their risings.

Fig (*Ficus*), a genus of Exogenous plants, belonging to the *Urticaceæ* or nettle order, but also included by some botanists in the *Artocarpaceæ*, or bread-fruit and mulberry order, and in a special section (*Moreæ*) of the latter group. The *Moreæ* have flowers in heads, spikes, or catkins; the embryo being hooked, and the albumen fleshy. In the F. the fruit is named *polygynæcial* or *anthocarpous*, and consists of a hollow 'receptacle' of fleshy nature, within which numerous male and female flowers are contained. The *receptacle* is the extremity of the peduncle or flower-stalk, which becomes hollow and modified to contain the flowers. The seeds are single-seeded carpels, imbedded in the pulp of the fruit. The figs form numerous species, of which the most familiar is the common F. (*Ficus Carica*). This plant is a native of the East, but is cultivated with success in S. Europe, and in Britain in hothouses, although sometimes figs may ripen in this country as outside-growing plants. The F. is the *teenah* of Scripture, and is the first tree mentioned by name in the Bible. The figs imported into Britain come chiefly from Turkey. They are sent in 'drums,' or small boxes, from Smyrna. Figs are eaten simply as fruits, but are also used as mild purgatives or laxatives, and in the form of cataplasms are applied to painful boils, &c. The pulp contains about sixty per cent. of a saccharine substance named *sugar of F.* The common F. appears as a low shrub or tree, the leaves being palmate and deeply cleft. In the East two crops annually are yielded. Other species of figs are the *F. elastica*, which yields India-rubber, and which is frequently cultivated as a house-plant, on account of its green leaves and handsome appearance. The Banyan (q. v.) tree is a species of F.—*F. Indica*; and *F. Rumphii* and *F. religiosa* are objects of veneration to the Hindus. Many other species are familiar to botanists, the juice of certain forms (*F. toxicaria*) being acrid and poisonous.

Fig'aro, a celebrated character introduced by Beaumarchais about the end of last century into three of his comedies—*Barbier de Seville*, *Mariage de Figaro*, and *Mère Coupable*—and adopted from them by such operatic composers as Mozart and Rossini. F. is a barber, who by his dexterity, and what is better expressed in French than in English as an *esprit net et decidé*, succeeds in outwitting every one with whom he comes in contact. F. is also used to designate a collection of the writings of Spanish humourists, and as the name of satirical journals published in France and in England. The first French newspaper of the name was started on the restoration of the Bourbons, the second in 1854, by M. Villemessant, by whom it is still conducted.

Fi'geac, a town of France, in the department of Lot, 32 miles N.E. of Cahors, situated in a deep picturesque valley, amid rich woods and vineyards, and of a very antique aspect. Its chief buildings are the church of St. Sauveur, which dates from the 11th c., and the Château de la Baleine, an old feudal fortress now used as a courthouse. F. arose from a monastery founded here by Pippin the Short in 755. It has some trade in wine, manufacture of linen, and dyeworks. Pop (1872) 5394.

Fight, Challenge to, by word or letter, is an indictable offence, punishable with fine or imprisonment. Any direct endeavour to provoke a challenge is a misdemeanour, though mere words which may tend to that issue—such as calling a man a liar or a rascal—are not necessarily criminal. See Duel.

Fighting Fish (*Macropodus pugnax*), a small fish belonging to the family (*Anabasidæ*) of the Climbing Perches (q. v.), and found in rivers and lakes in Siam and other parts of S.E. Asia. It is exceedingly pugnacious, and when several of them are

brought together in a confined space, they afford sport to the spectators by their combats, the exhibitions of which are said to be licensed by the state. Their anal and dorsal fins are elongated, and their colours, when they are excited, are very brilliant.

Figue'ras (Span. 'fig-trees'), a town in the province of Cataluña, Spain, 60 miles N.E. of Barcelona. It stands in a fertile plain near the confluence of the Muga and Manol, and is defended by the fortress of S. Fernando, which has been repeatedly taken by the French. F. has manufactures of paper and leather. Pop. 8350.

Fig'uline. See POTTER'S CLAY.

Fig'urantes, the name applied to the general body of dancers in a ballet—those that dance *en masse*, or are posed in the background—as distinct from the principal dancers.

Fig'urate Numbers are the numbers of a series formed from an arithmetical progression according to a certain definite rule. The *n*th number of the first series is equal to the *sum* of the first *n* numbers of the progression; and each term of the second series is formed in the same manner from the first series of F. N., and so on. *Polygonal* numbers are particular cases of F. N. Thus the series bearing the name of an *n*-sided figure is the first series of F. N. formed from the arithmetical progression whose first term is unity and whose common difference is $(n-2)$. The following are the first three series of polygonal numbers:—

Triangular	1	3	6	10	15	21	&c.
Quadrangular	1	4	9	16	25	36	&c.
Pentagonal	1	5	12	22	35	51	&c.

Pyramidal numbers are the F. N. formed from the polygonal numbers. These appellations, introduced as expressive of the properties of each class, very rarely appear in modern works. The operation is evidently the inverse of the fundamental operation in the calculus of finite differences, and is in itself of little practical importance.

Fig'ure, in geometry, is a finite space bounded by lines or surfaces. In arithmetic it is a name commonly given to the Arabian numerals.

Figure Stone. See SOAP-STONE.

Fig'worts (*Scrophulariaceæ*), the name given to a large natural order of Exogenous plants, represented by the calceolaria, veronica, foxglove (*Digitalis*), Eyebright (q. v.), Euphrasia (q. v.), and other genera. The plants of this order are herbs or small shrubs, with opposite, alternate, or whorled leaves. The calyx consists of four or five parts, and the corolla is irregular. Two or four stamens exist, five being rarely developed. The ovary is bilocular and the fruit, a capsule, or more rarely a berry. The seeds are albuminous. Many of the F. are showy plants; they are found in both cold and tropical regions.

Fiji', Feejee', or **Viti Islands,** an archipelago in the S. Pacific, lying between 15° 40′ and 20° S. lat., and 177° E. long. and 178° W. long. The number of islands composing it is about 255, of which only 80 are inhabited, many being mere pinnacles of rock rising out of the sea. The total area of the group is about 8000 sq. miles, more than two-thirds of which are occupied by the two large islands of Viti Levu (4112 sq. miles) and Vanua Levu (2432 sq. miles). The areas of the islands of Taviuni and Kandavu, the next largest, are 217 and 124 sq. miles respectively. The archipelago was discovered by Tasman in 1643, and in 1776 was sighted by Captain Cook, though he did not touch there. In 1796 several missionaries proceeded to F., with the intention of starting a mission, but the threatening attitude of the natives caused them to abandon the enterprise without landing. In 1804 some convicts who had escaped from New South Wales in an open boat reached F., and became the advance guard of a chance white population of shipwrecked and runaway sailors. A Wesleyan mission was established in 1835, and in the same year commercial relations with New South Wales were set on foot. It was not until 1866, however, when an influx of European settlers from New Zealand began, that the trade of F. emerged from obscure insignificance. From that date settlers and capital poured into the group from the Australasian colonies, and at length, after repeated applications to that effect, both from the native king, Cakobau or Thakombau, and the European inhabitants, the islands were annexed to Britain as a crown colony. The annexation took place on 30th September 1874, but it was not until 1st September 1875 that the colony was formally proclaimed by its first governor, Sir Arthur Gordon.

The F. Islands are of volcanic origin, and consist almost entirely of steep mountains sloping abruptly to the sea, and girt by coral reefs. The climate being humid and the soil fertile, the vegetation is luxuriant. Cocoa-nut oil, yams, tortoiseshell, and *bêche de mer* were the staple articles of native commerce; but since European settlement fairly commenced, cotton, sugar, tobacco, coffee, and maize have been successfully cultivated. The chief obstacle in the way has been the scarcity of suitable labour, for the natives being indolent and inefficient, it has been found necessary to import labourers from neighbouring groups of islands. This traffic is now strictly regulated under Acts of the imperial legislature, and a number of armed cruisers are employed to see that the law is obeyed.

The aborigines of F. belong to the Melanesian race, and their colour varies from nearly black to a dark olive, which is the prevailing shade. They are a weak and cowardly race, and formerly indulged in cannibalism, which the missionaries succeeded in abolishing in 1854. In 1875 the islands were decimated by an epidemic of measles, introduced by H.M.S. *Dido*, by which it is estimated that 50,000 were carried off. The number left, according to an official calculation, is about 105,000, of whom 85,000 are professed Christians. The great majority of the latter are converts of the Wesleyan mission, which has 1000 native places of worship in the group. The Roman Catholic mission, established in 1846, has also a good many native members. The heathen natives, who are now confined to the more inaccessible mountain districts, are known by the name of 'devils.' They still give trouble occasionally to the Government.

The capital of F. is Levuka, situated on the small island of Ovalau. Its population at the census of 1876 was 1500, of whom half were whites. The imports of F. in 1875 amounted to £109,720, and the exports to £85,690. The island of Kandavu is the calling place of the mail steamers running between San Francisco, New Zealand, and New South Wales. The group is advantageously situated for becoming the entrepôt of a large portion of Melanesia and Polynesia; and now that a stable government exists, the islands may be expected to advance rapidly in prosperity. See J. H. de Ricci's *Fiji* (1875).

Fila'ria. See GUINEA-WORM and THREAD-WORM.

Fil'bert. See HAZEL.

File (Old Eng. *feol*, Ger. *feile*, allied to the Lat. *polio*, 'I polish'), a bar of cast steel, having one or more of its surfaces notched into teeth, which is used as a tool for making an approximately smooth surface upon metals or other hard substances. English-made files are known as Lancashire and Sheffield files, the two principal seats of their manufacture being Warrington and Sheffield. They are all made by hand, the attempts to manufacture them by machinery not having succeeded hitherto in this country. The process is as follows:—The *blank* is placed upon an anvil in front of the workman, and held in place by a foot-strap. The cutter then makes a series of nicks with a chisel in the surface of the blank, their direction making an angle of about 55° with the axis of the F. He is guided in fixing the position of each nick by bringing the chisel into contact with the burr thrown up at the last stroke; but the exact distance apart and depth of the cuts he regulates entirely by the inclination which he gives to the chisel and the weight of the hammer and force of the blow. So wonderful is the skill of some of the F.-cutters, that Mr. Holtzapffel, a great authority on all matters connected with tools, says he has known files with *nearly three hundred* cuts per inch. When the F. has been cut upon both sides in the way described, it may be at once straightened and hardened, and will be then ready for use. A F. thus made is called 'float-cut,' or 'single-cut.' In the majority of cases, however, another series of cuts is made on each side, crossing the first, and the ordinary 'double-cut' F. is produced. In files intended for use with softer materials, such as hard wood or bone, a pointed punch is used instead of the chisel, files made in this way being called 'rasps.' Each of the three classes of files—double-cut, single-cut, and rasp-cut—is made in about half-a-dozen degrees of fineness, the coarsest being called ***rough***, the medium kinds ***bastard*** and ***second-cut***, and the finest ***dead-smooth***

or *superfine*. All these varieties are made of many different lengths and cross sections, for different kinds of work. Unless otherwise mentioned, a F. is understood to have two flat parallel faces; a 'half-round' F. has one surface slightly convex, a 'three-square' F. is triangular in section. Square and round files, and other kinds, are also occasionally used.

File-Fish, the name given to various Teleostean fishes belonging to the order *Plectognathi*, and to the genus *Balistes*, *Diodon*, &c. Their bodies are covered with numerous spines, the presence of which has suggested their popular name. They are also known as 'trigger-fishes, 'urchin-fishes,' and 'globe-fishes,' the latter name being given on account of their power of distending their bodies at will with air.

Filia'tion, in Scotch law, means the determination of a child's paternity. The presumption of law is that he is the father whom the marriage indicates (*Pater est quem nuptiæ demonstrant*), but this presumption may be overcome by showing that it cannot be fact. (See BIRTH, BASTARD AND BASTARDY.) Ten months is held by law to be the limit of gestation, but anterior intercourse is held to be an important article of proof. Actions of F. are usually brought in the Sheriff Court, but they may be brought in the Court of Session.

Filica'ja, Vincen'zo da, an Italian poet, born of a noble family at Florence, December 30, 1642. He was educated at the University of Pisa, and soon became distinguished as a jurist in his native town, where, in 1673, he was made a senator, and married one of the great house of Capponi. Six *canzoni* on Sobieski's raising the siege of Vienna by the Turks in 1683 made him known through Europe, and won him the congratulations of many sovereigns. A poem in praise of Christina of Sweden brought him liberal gifts from that queen, and in 1702 he was made one of the chief magistrates of Florence. He died September 24, 1707. F.'s odes, which are full of deep feeling, have now fallen into neglect, but his sonnets, partly devotional, partly breathing a sad scornful patriotism, and cast in vigorous and choice language, are still popular; the two finest, *La Providenza* and *L'Italia*, being known throughout the Continent. *L'Italia* is translated in Byron's *Childe Harold*, canto iv. His private character seems to have been almost without a blemish. His works were published shortly after his death; the best edition is that of Venice (1762). See his correspondence with Francesco Redi, Menzini, and Gori; Fabroni's *Vite Italiane*, and Tiraboschi's *Storia della Letteratura Italiana*.

Fil'ices. See FERNS.

Fil'igree (Fr. *filigrane*), fine gold and silver wire twisted into elegant forms, chiefly for use as personal ornaments. F. work was practised by the Etruscans, and their gold ornaments, combining fine wire (Lat. *filum*, 'a thread') with very minute beading (*granum*, 'a grain or bead'), cannot be equalled by modern goldsmiths. In Eastern countries great minuteness and delicacy are attained in F.-work with the rudest appliances. The Chinese are extremely adroit in silver F.; so also are the natives of Cuttack in India. Durable silver F. is largely manufactured in the S. of Europe.

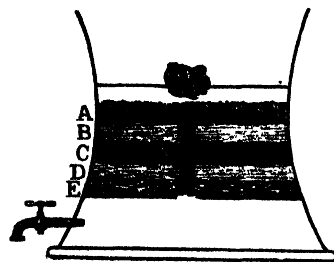
Filio'que is a word which was subsequently added to the Nicene Creed, and formed a bone of contention between the Latin and Greek Churches. The Nicene Council (325), being chiefly concerned to establish the deity of the Son in opposition to the Arians, merely affirmed the existence of the Holy Spirit, without defining the nature and relations of the third person of the Trinity. Macedonius, Bishop of Constantinople (342), and many others, maintained the Holy Spirit to be a created being, as the Son was regarded by the Arians, and subordinate to the Son, as the Son was to the Father. By the Council of Constantinople (381) the simple phrase of the Nicene Creed, *and in the Holy Ghost*, was expanded into *and in the Holy Ghost, the Lord and giver of life, who proceedeth from the Father, who with the Father and the Son together is worshipped and glorified, who spake by the prophets.* But as this only affirmed that the Spirit proceeded from the Father, room was left for doubt whether the Council denied the procession from the Son. If it were meant that the Spirit did not proceed from the Son as well as the Father, this favoured the notion that the Son was subordinate to the Father; if the Spirit proceeded from both the Father and the Son, this seemed to be placing the Spirit in still greater dependence, namely, on two persons instead of one. Accordingly, the Greek fathers merely taught the procession of the Spirit from the Father, without denying the procession from the Son. The Latin fathers, on the contrary, taught the procession of the Spirit from both the Father and the Son, and at the third Council of Toledo (589)—or, according to Bingham, at Bracara (411)—inserted in the Creed of Constantinople the phrase *F.*, making it run:—'and (I believe) in the Holy Ghost, . . . who proceedeth from the Father *and the Son*,' &c. The Churches of the East refused to accept this as an addition to the faith of the Church, or to alter a single word of the Nicene Creed. This led to a schism between the two Churches, which was never thoroughly healed up, although a formal union was effected at Florence, 1439. See Blunt's *Dict. of Doctr. and Hist. Theology* (1872); *Pearson on the Creed*; Neale's *Hist. of the Holy Eastern Church*.

Fil'ipo d'Argi'ro, San, a town of Sicily, in the province of Catania, 27 miles W.N.W. of the town of Catania. It has a ruined Saracenic castle, and its church of St. Philip, whence it derived its name, was a great resort of pilgrims in the middle ages. Pop. about 7000. F. occupies the site of the ancient *Agyrium*, one of the oldest and wealthiest cities of Sicily.

Fill'an, St., more properly **Faolan**. There were two ecclesiastics of this name who flourished in the 7th and 8th centuries, and whose memories are still preserved both in Scotland and Ireland. The *first* is called Faelan the leper of Rath-erann in Alba, and Cill-Fhaelain in Laighis, Leinster, Ireland. His day in the Irish calendar is June 20. Rath-erann is now known as Dundurn, in the parish of Comrie, Perthshire, and is near the E. end of Loch Erne (in Gaelic Loch Erinn), where there is also the village of St. Fillan's. There is a hill known as Dun-Fhaolain, at the foot of which is a well dedicated to the saint, and which in 1794, when the old *Statistical Account of Scotland* was published, was visited by scores of people who had faith in the healing virtues of its waters. The *second* Faolan is known as of Strath-Fillan, likewise in Perthshire, but quite on the edge of the old Drumalba, which separated Dalriada from the Pictish kingdom, or Argyleshire from Perthshire. His maternal grandfather is said to have been king of Leinster; his mother, St. Kentigerna of Inchcailleach, in Loch Lomond. In the Irish calendar he is styled of the church of Cluain Maoscna in Westmeath. Kilallan in Renfrew, written in old records Kilheylan, is named after him, and ought to be written *Cill Fhaolain*. In Strath-Fillan there are still some remains of a religious building consecrated to him. Some call it a priory, others a church. There is great sacredness attributed to this building, as well as to the river which flows beside it; and until a very late period frightful barbarity was practised in imparting their curative virtues to unhappy patients who needed them. Lunatics were brought by their friends and plunged in the river just at sunset, then bound hand and foot, and left all night in the ruins beside what is called (erroneously) St. Fillan's tomb. If in the morning they were found bound as they had been left, the case was given up as hopeless; but if the knots were untied, it was regarded as the merciful work of the saint, and the sufferers were for ever free of their malady. One very interesting relic of this second F. is still preserved, the silver head which belonged to his crosier, and known as the 'quigrich' (*coigreach*, 'stranger,' 'pilgrim'). In 1487 the right of keeping it was confirmed to Malise Doire or Dewar as its hereditary guardian. It remained in this family till 1877, when it was purchased from Mr. Alexander Dewar of Canada for the Antiquarian Museum, Edinburgh. (Dewar, originally *Deòraidh*, signifies first 'pilgrim.' It afterwards came to be applied to the bearer of the baculus or staff of a preacher; latterly it passed into a family name.) It is said by Hector Boece that Scotland owes much to another relic of St. F. At the battle of Bannockburn Bruce found himself and his companions greatly comforted and strengthened by St. F.'s crosier being carried in a silver shrine before them. After the victory he ordered the priory of the saint to be rebuilt.

Fill'et (Fr. *filet*, Lat. *filum*, 'thread'), a small flat face or band used both in Classic and Gothic architecture to separate mouldings.

Fillet, in heraldry, a diminutive of the Chief (q. v.), and containing one-fourth of it. The chief, unlike other honourable ordinaries, has only one diminutive (Boutell and Aveling).



Fillibust'ers. See BUCANEERS.

Fill'more, Millard, D.C.L., the thirteenth President of the United States, was born at Summer Hill, New York, January 7, 1800. He was apprenticed to a wool-carder, but afterwards studied law, and was admitted to the bar in 1823. He was elected to the New York Assembly in 1829, and was in Congress 1833-35, and 1837-41, where he supported J. Q. Adams on the slavery question. He was made in 1847 comptroller of New York state, in 1848 Vice-President, and in 1850 President of the United Sates. He retired from public life in 1856, and died March 8, 1874.

Filtra'tion is a mechanical process for removing substances suspended, or sometimes even dissolved, in water and other fluids. As the fluid passes through the fine pores of the filtering medium while suspended, matter is retained either on its surface or in the excessively fine meshes it presents. F. is of the greatest industrial importance in many chemical manufactures, as, for example, in the refining of Sugar (q. v.). In the chemical laboratory, also, it is continually resorted to in order to separate precipitates which would only deposit slowly by mechanical subsidence. In laboratory practice, a cone of unsized paper is usually placed within a funnel, and the fluid to be filtered is allowed to percolate slowly through it.

On a great scale F. is generally required for the domestic water supply of any community. The water is first collected into reservoirs, where all heavy impurities subside, and from these it passes by gravitation through filtering beds, which are variously formed according to circumstances. Usually they consist of a substratum of gravel from 2 to 3 feet thick, covered with fine sharp sand to a depth of from 18 inches to 2 feet. A filter of this description removes by purely mechanical sifting all suspended matter, but it has little influence on dissolved organic impurities. Thick layers of sand, however, retain a good deal of dissolved mineral matter, such as common salt, and are said effectually to separate lead in solution. The sand in such F. beds gradually becomes encrusted with matter deposited from the water, and requires repeated cleaning or renewal.

In dealing with water on a smaller scale, it is possible to adopt many other expedients for F., and among the substances employed, nothing is equal in importance and efficacy to animal charcoal. The charcoal employed is freed by the action of acid from the phosphate and carbonate of lime, and it should be so compacted that the water is kept from percolating through it too quickly. By some manufacturers the charcoal is compressed into solid blocks. Wood and peat charcoal are also employed, and the charcoal obtained in Stanford's process for treating seaweed has also been shown to be an effective filtering agent. Combinations of iron and charcoal, powdered iron ores, manganese, mixed sand and carbon, sponge, flannel, and other woolly substances, have all been used in the fabrication of filters, and numerous patents have from time to time been secured for special forms or arrangements in domestic filters. A filter in extensive use in Paris consists of a series of diaphragms of wool prepared first with alum and cream of tartar, after which they are dyed in a solution of gall-nuts, and washed with sodium carbonate. Of the numerous forms of domestic filter, none is more effective than that shown in section in the accompanying figure, and which is manufactured by the Port Dundas Pottery Company, Glasgow. In this filter the water passes first through a piece of sponge, which is tightly plugged into an orifice in the upper reservoir. It then meets a stratum (1) of fine gravel A, and (2) of calcined sand B, of a pure white quality, after which it passes through a layer of animal charcoal C, well compacted, and again it percolates through another bed of fine sand D, and of gravel E. For the use of soldiers in campaign, or for travellers, a capital device is the pocket-filter, a small case or box containing animal charcoal, fitted at the top with an elastic tube, and pierced beneath with numerous small holes. The water to be drunk is drawn by suction through the charcoal and tube.

Filter.

Air Filter.—Charcoal has great power of absorbing noxious gases and vapours, a property taken advantage of for catching emanations from sewers, and for disinfecting the air passing out of fever wards in hospitals. Charcoal filters for placing on the mouth are useful in presence of very impure air, as in passing through smoke in a burning house. The filter chiefly recommended for such a purpose contains a layer of pure cotton wool, next the same saturated in glycerine, then powdered charcoal, followed by cotton saturated in glycerine, and dry cotton.

Fimbriated (Lat. *fimbria*, 'a border'), in heraldry, 'edged with a metal or tincture.'

Finale, in music, the last movement in a symphony or other instrumental composition, or the conclusion of the act of an opera. In the latter case its character is determined by the nature of the action; in the former it is always a quick movement.

Fi'nal Judg'ment, a term of Scotch law denoting in its widest sense a judgment which exhausts the merits of a cause, and is not subject to review. But the term is more frequently used in contradistinction to the term Interlocutory Judgment (q. v.). See also APPEAL.

Final Perseve'rance of the saints or of the elect is a tenet in the Calvinistic system of theology which flows necessarily from the doctrine of Election (q. v.). The logical chain of which F. P. is the last link is as follows:—From the mass of fallen men God elected a certain number to eternal life. For the salvation of those thus chosen God gave his own Son to become man, to obey and suffer for his people, thus making a full satisfaction for sin, and rendering the ultimate salvation of the elect absolutely certain. While the Holy Spirit in his common operations is present with every man, his certainly efficacious and saving power is exercised only in behalf of the elect. This efficacious grace is irresistible, not only at the time of conversion, but subsequently amid all the frailty and corruption of human nature, because it is the exertion of almighty power carrying out the divine purpose. With these premisses it is a moral impossibility that any of those for whom Christ died, and who subsequently become partakers of his grace, can fall from that grace, either totally—so as at any period of their lives to commit sins so heinous, and to persevere in them so obstinately, as to forfeit entirely the divine favour—or finally, so as not to be saved at last. See *Westminster Confession of Faith*; Hodge's *Systematic Theology* (Edinb. 1873).

Finance' means the management of revenue and expenditure, whether on a large or on a small scale, relatively to each other. See DEBT, NATIONAL; BALANCE OF TRADE; BULLION; BANK, BANKING; CAPITAL ACCOUNT; and DOMESTIC MANAGEMENT. The word *finances* denotes money itself.

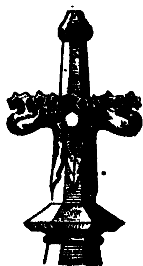
Finch, a term applied indiscriminately to a large number of small song-birds, belonging to the order *Insessores* (q. v.). The family *Fringillidæ* is that which includes the great majority of the typical finches. (See CHAFFINCH, BULLFINCH, &c.) The *Fringillidæ* form a family of the *Conirostres* (q. v.).

Find'horn, a river of Scotland which rises in the Monadliadh Hills, Inverness-shire, flows through the counties of Inverness, Nairn, and Moray, and after a course of 90 miles enters the Moray Firth. The scenery along the F. is very fine. The river is broad and shallow, and often dangerous in flood. The village of F. (pop. 701), in the county of Moray, at the mouth of the river F., has large herring-fisheries.

Finding Goods, Law Regarding. It has been decided in England by the Court of Criminal Appeal (Reg. *v.* Wood, and Reg. *v.* Moore, 1861) that if the finder appropriates goods believing that the owner cannot be found, and believing the goods to be lost, the act is not theft; but that if he believe the owner can be found, the act is larceny. In the case the prisoner had found a bank-note, and had no means of knowing its owner. He was, however, told who the owner was. He then changed the note, and applied the money to his own use. He was held not guilty of larceny, because when he found the note he did not know that the owner could be found. The decision certainly seems strange, causing one to wonder what it would have been had the information as to the owner been received simultaneously with the finding, as suppose the money had been in a purse along with the owner's card having his name and address

on it. However obscure the law of England may be on the subject, the moral obligation is clear enough.

Fine, in English law. This was an amicable composition by leave of the court, by which lands were declared to belong to one of the parties claiming them; and by it all the parties were barred who did not claim within a short period. But 3 and 4 Will. IV. c. 74 abolishes fines and recoveries, and substitutes more simple modes for assuring lands and barring estates tail. F. is also a sum of money paid for the grant of lands by lease, or on the admission to a copyhold interest. F. also signifies a pecuniary penalty imposed by a court of justice for an offence against the law.



Fin'gal, more properly **Fionn**, the great hero of Gaelic, as Arthur is of Cymric romance. It is impossible to determine whether he belonged to Ireland or to Scotland, or what was the exact period in which he lived, while some even maintain that he existed in name only. But if every national hero is a real person, however much his attributes be exaggerated by popular imagination, then perhaps the historical reality of F. may be conceded. In the *Book of Deer* (12th c.) we have mention of the *Féine, i.e.*, the followers of Fionn; he is represented as frequenting both the N. of Ireland and the N.W. of Scotland. There are many old heroic ballads, belonging alike to Ireland and to Scotland (see Mr. Campbell's *Book of the Féine*, 1872), in which F. is celebrated both as a great warrior and as a generous man; but in Ossian (Macpherson) the Gaelic muse has adorned him with every quality which can raise admiration or call forth affection. See OSSIAN.

Fingal's Cave. See STAFFA.

Finger-Board, in various stringed instruments, a piece of wood—generally ebony—lying underneath the strings, and upon which they can be pressed by the fingers so as to give the sounding part of them the required length.

Fingers. See HAND.

Fin'ial (Lat. *finis*, 'end'), the ornamental termination which in Gothic architecture usually surmounts and completes the design of spires, pinnacles, gables, the canopies of windows, porches, &c. By early writers the term was used to denote the pinnacle, canopy, or gable itself, as well as its ornamental termination. Finials proper first came into use in the 12th c.—although in the buildings of the ancients there are traces of foliated and other terminations surmounting the pediments—and during the 13th c. they were brought to perfection as an architectural ornament. During the 15th and 16th centuries it was customary to surmount finials with a gilded vane. Stone, wood, and metal were the materials in which these ornaments were carved; but the F. of modern times is usually a pyramidal termination in light metal-work, the designs being generally foliage and scrolls.

Finial.

Fi'ning. Some liquids holding impurities in suspension are cleared by straining through a porous body (see FILTRATION); others again, such as beer and wine, are clarified by adding substances which either precipitate or raise to the surface the impure matter; the latter process is termed F. The chief finings used are albumen, gelatine, blood, lime, acids, and alcohol. Beer and wines are clarified by dissolved isinglass, which combines with the tannic acid of the liquors, and subsides to the bottom, along with the impurities, in the form of a flocculent mass. In the case of wines containing little tannic acid, such as Burgundy, extract of nut-galls is added with the isinglass to the wine, to prevent decomposition by robbing the wine of one of its natural preservatives. White wines are cleared in Spain with powdered marble; gypsum and sand are elsewhere used. Lime or alum greatly assists the precipitation of impurities in beer or cider. The juices of plants may be clarified by heat, which calls into action the albumen present in them. Syrups are fined with white of egg, which coagulates with heat, and rises with the impurities, forming a scum on the surface.

Finistère' or **Finisterre** (Lat. *finis terræ*, 'land's end'), the most westerly department of France, once a portion of the province of Brittany, and lying between the English Channel and the Atlantic. Area, 2595 sq. miles; pop. (1872) 642,963. The climate is damp and dull. F. is a wild, hilly district. The coasts are deeply indented, and lined with rugged granite rocks; the interior is partly rich arable land, partly marshes and wide heaths. F. is watered by many small rivers, the chief being the Penzé and Aberbenoit, flowing into La Manche; the Odet, Arven, and Ellé, running S.; and the Aulne, Elorn, and Penfeld, flowing E. Barley, wheat, rye, flax, and hemp are largely cultivated, and much cider is made. There are valuable mines of silver and lead, iron and zinc are found, and much granite is quarried. The pilchard fisheries of the coast employ many of the inhabitants. The chief manufactures are of linen, canvas, ropes, leather, paper, pottery, sugar, soap, and tobacco; there is also some shipbuilding. F. comprises five arrondissements; the principal towns are Brest (the capital), Quimper, Landerneau, Morlaix, and Quimperlé.

Finisterre, Cape (Lat. *finis terræ*, 'land's end'), a cape on the N.W. of Spain, in the province of Galicia. F. was the Roman *Artabrium*, from the *Antabri* who dwelt there.

Fin'land, the most north-westerly province of Russia, is bounded W. by Sweden and the Gulf of Bothnia; N. by Norway; E. by the Russian governments of Archangel, Olonetz, and St. Petersburg; and S. by the Gulf of F. It is about 750 miles from N. to S., and on the average about 185 miles broad. Area, 140,000 sq. miles; pop. 1,857,035, whereof about 200,000 are Swedes, 40,000 Russians, 50,000 Lapps, 1000 Germans, and the rest Finns. The shores of F. are much indented, and enclosed with belts of islands; the interior is a plateau 500 700 feet high, precipitous towards the S., more level in the W., and sloping almost imperceptibly to the N. and E. In the N.W. part there are mountains of 2000 feet. F. consists in general of a mass of granite interspersed with trap, and yields some copper and lead, and many useful kinds of stone. Nitre, sulphur, arsenic, and iron are also found. The vast number of lakes and swamps, covering one-third of the entire surface, gave rise to the native name of F.—*Suomesimaa*, or 'fen-land.' The chief lakes are Ladoga, Saima (which drains two extensive chains of lakes, the largest among which are Kalla on the W. and Pieli), Näsi, Ulea, and Päjäne, with the Kymene as its outlet into the Gulf of F. The chief other rivers are the Tornea, which falls into the Gulf of Bothnia; the Tana, running into the Tanafjord in the Arctic Ocean; Kemi, Simo, Ijo, and Ulea, which fall into the Gulf of Bothnia. The climate of F. varies greatly, the mean temperature of Abo, under 60½° N. lat., being 40° F.; while that of Enontekis, under 68½° and 1370 feet above sea-level, is 27° F. The comparatively high summer temperature (that of Abo is 60° F.) has great influence on vegetation. F. is said to contain 1000 flowering plants. Corn is cultivated S. of the great lakes, but also to some extent in the fen-country, and even further N., and the oak thrives on the Kumo and about Björneborg. In the extensive woods covering most of F. are found bears, elk, wolves, and wildfowl, and the rivers and lakes abound in fish. Before the colonisation of F. by the Swedes, it was inhabited by petty tribes, the names of some of which survive in the names of the old provinces—*e.g.*, Oesterbotten, at the N. end of the Gulf of Bothnia, inhabited by the Kainu or Quains; F. proper, or Suomi, by the Suomians; Tavastland, by the Tavastians or Hæmians; Savolax and Karelia, by the Savolaxians and Karelians. F. is now divided into eight governments.—Nyland, Abo, Tavastehuus, Vasa, St. Michael, Viborg, Kuopio, and Uleaborg. The prevailing religion is the Lutheran, but about 40,000 Finns belong to the Greek Church.

In the 12th and 13th centuries F. was subdued by the Swedes, and gradually received Christianity and culture from its conquerors. While a Swedish province, it often suffered from the wars with Russia, of which it was the theatre. The Peace of Frederikshamn, in 1809, gave the country to Russia, and fixed the Tornea as the Swedish boundary. Under Russian rule the constitution is essentially unchanged. There are four social classes—nobles, clergy, burgesses, and farmers, the latter mostly freeholders. On the whole, F. has a perfectly independent internal government, with special customs-frontiers and financial arrangements proper to itself. The average revenue is about £429,000, and there is a public debt of £6,435,000, two-thirds of which was contracted by extensive construction of railways. Russian garrisons lie in the fortresses, but all public functionaries

must be natives of F. The navy crews of F. are levied voluntarily. All Finnish affairs are laid before the 'Grand-Duke' (*i.e.*, the Czar) by a Secretary of State, who is the head of the Imperial F. Office. In F. itself the highest authority is the Imperial Senate for F., of which the Governor-general is Speaker, while a procurator watches over the administration of justice. There is a separate system of public instruction, and education is almost universal. The Finns are good seamen; their merchant shipping has a total burden of about 270,000 tons. The chief towns are Helsingfors (q. v.), Abo, Viborg, Björneborg, and Uleaborg; none of the rest reach 4000 inhabitants. See Stockfleth's *Bidrag til Kundskab om Finnerne* (*i.e.*, the Lapps) *og Dito om Qvænerne* (*i.e.*, the Finns) (1848); Milner's *The Baltic, its Gates, Shores, and Cities* (1854); Topelius' *F. fræmställdt i Teckning* (1860); Gerschau's *Versuch einer Gesch. F.'s* (1821); *Zeitschrift der Gesellschaft für Erdkunde* (vol. vi. 1871). See FINNS.

Finland, Gulf of, that part of the Baltic, 240 miles long, and from 10 to 70 miles wide, stretching from W. to E. between the coasts of Finland, St. Petersburg, and Esthonia. Its waters are only slightly salt. Along the Finnish coast it is studded with islands, rocks, and shoals, which render its navigation difficult. There are several excellent harbours, as Kronstadt and Revel, which, with Sveaborg, are also fortresses of the first rank.

Fin'lay, George, LL.D., one of the best of recent historians, was born in Scotland early in the present century, and in 1822 went out to Greece and fought in the cause of Greek independence. He then settled near Athens, and after an unsuccessful effort to better the state of agriculture in the country, devoted himself to writing the history of Greece from the time of Alexander, when he believed the history of the modern Greek nation began, down to the present day. An ardent Philhellene, he did not shrink from exposing the weaknesses of Greece in a series of shrewd, bold, and vigorous letters to the *Times*, which occasionally gave offence both in England and in Greece. His works were coldly received, but his studious zeal remained unchilled. He died January 26, 1875. F.'s chief writings are *Greece under the Romans* (1843, 2d ed. 1853); *History of the Byzantine Empire* (1852, 2d ed. 1856); *History of the Byzantine and Greek Empires* (1854); *History of Greece from its Conquest by the Crusaders to its Conquest by the Turks* (1851); *History of Greece under Othoman and Venetian Dominion* (1854); and *History of the Greek Revolution* (1861). These works have revolutionised our ideas of mediæval Eastern history, disclosing for the first time the true nature of the Eastern empire, and also shedding fresh light on the annals of modern Greece. They show deep, accurate learning, vivified by the author's strong practical intellect and generous love for the country, much of whose history he was the first to unfold to Western Europe.

Fin'mark, a province (*amt*) of Norway, and the most northerly part of Continental Europe. Area, 20,000 sq. miles; pop. (1871) 22,500. F. is a high barren tableland traversed by a range of snow-clad mountains, rising to a height of 4000 feet; its coasts are thickly studded by rugged islands and indented by wild narrow fiords. Barley and potatoes are grown near the sea, and the uplands support large herds of reindeer. The cod-fisheries occupy most of the inhabitants, and are very valuable, above 20,000 barrels of cod-liver oil being, on an average, annually produced. The inhabitants are partly Norwegians, but mostly Finns. The chief town is Hammerfest (q. v.).

Finn'er Whale, a name given to various kinds of whales belonging to the family *Balænidæ* or whalebone whales, and derived from their possessing a soft dorsal fin. Finner whales are of large size—the *Physalus Boops* or rorqual sometimes attaining a length of 90 or 100 feet. They are represented by the genera *Megaptera*, *Balænoptera*, in addition to *Physalus*. They are also named 'furrowed' whales, from the fact that the skin is plaited or folded. The whalebone plates are very small and commercially unimportant.

Finn'ish Language and Literature. Finnish, the most perfect of Ural-Altaic languages, is so rich in declensions and conjugations that Schwarze and Europæus class it among inflective rather than 'agglutinating' forms of speech. But its main characteristics discountenance the theory of its Aryan origin. The noun is without inflection, cases (fourteen in all), numbers, and genders being denoted by additional words. The prepositions (none of which are of pronominal origin) take the form of suffixes; and the verb, having only two tenses, a present and a past, expresses the future by adding some word or other which can indicate futurity. The syntax is comparatively rude and formless, and in all its wealth of cases there is scarcely a definite nominative or accusative; yet the language is so musical that Rask called it the 'most harmonious of tongues,' and, with the single exception of Magyar, it is the only branch of the Ugric (see FINNIC) stem in possession of a literature.

Swedish-speaking Finns fill the chief professional and mercantile positions in Finland. The people are as much Swedish in culture as the Irish are English, a large number of the Swedish-speaking Finns not even understanding Finnish. Yet the language has not wanted cultivation; it possesses translations of the best foreign works of a religious or popular character, and has a curious and ancient folk-poetry of its own. It was long known that there lived amongst the Finns a great number of lyrics known as *Runot* ('Runic songs'). These poems, some of which are late, others are witch-songs from heathen times, are collected under the title of *Kanteletar* (3 vols. Helsingf. 1840). It was also known that there were *improvisatori* among the Finns, as Paavno Korhoinen (1775–1840), whose poems have been collected from oral recitation into a volume. But in 1835 Lönnrot awoke general astonishment with the discovery that many of these *Runot* could be dovetailed into a true and noble epic, based on the old myths; it came out under the title *Kalevala*; but so many more fragments were afterwards found, that the edition of 1849 comprises thrice as many verses, divided into fifty songs. It was translated into Swedish by Castrén (1841), into French by Le Duc (1845), and into German by Schiefner (1852). In recent years the language has been much studied by the Finns themselves, and the Russian Government's careful encouragement of Finnish literature is well seconded by the eagerness of the peasantry for printed matter in their native tongue.

Finns, Finn'ic. The F. seem to be identical with the *Phinnoi* of Ptolemy and the *Finni* described by Tacitus as leading a miserable nomadic life in the N.E. of Europe, and together with the *Venedi* ('Venedi' in Pliny, the 'Wends') or Slavs (q. v.), bordering on the *Germani*. They are classed by philologists as one of the five sections of the Northern Turanian (q. v.) or Ural Altaic family. The wide diffusion of F. races at the present day, as well as the allusions to them in Russian and Scandinavian writers, prove them to have been the oldest known inhabitants of Russia and Scandinavia. Yet, like other races composed of detached tribes, not recognising their own unity, they gave themselves no common name, *Finner* being the term applied to them by the Scandinavians and Germans, while the Russians knew them as *Tchud* (Chudians), in which some recognise the famous name of Scythians. Each branch of the F. stem formed a separate community, with its own name and customs. The people composing one of these, living in what is now called Finland (q. v.), named themselves *Suomalainen* (Suomians) or 'swamp-dwellers,' from the character of their country. Now, in the Germanic languages *fen* means swamp, and probably their German name is but a translation of their native name, which contains a word common to the F. tongues; for example, the Lapps, another F. race, call themselves *Samer* or *Sabmer*, and the same root appears in the name of the allied *Samoieds* or *Samoyedes* (q. v.). The ancient F. were in some respects superior to their more powerful neighbours, and though perhaps of shorter average stature, were strongly built and warlike. They were skilful in smelting and working metals, and especially renowned for their sorcery, a peculiar development of a mythology which influenced greatly that of the early Scandinavians, and was the origin of a rich popular poetry amongst themselves. *Fin* was a title of honour given to great Norwegians, and the leading families of Scandinavian kings and gods were traced to F. sources. But the patriarchal life of isolated tribes precluded political organisation, and they were never able effectually to join in resisting the attacks of neighbours who at first invaded their lands as robbers of their costly furs, and afterwards as zealous Christian proselytisers. From a remote period Norwegian chieftains levied *Finneskat* ('Finn-tax') in Finmark, a district extending from the White Sea to the banks of the Dvina, the abode of the Bjarmians. Erik the Saint of Sweden subdued Nyland or S. Finland in 1156, and in the 13th c. Swedish Christianity

and culture took firm root. After this Russian conquest began. The princes and merchants of Novgorod penetrated into the country, and wisely developed its resources; it became, so to speak, Russianised, and missionaries gradually converted many of the inhabitants to the Greek faith. The F. were peaceful subjects, and Finland was the first and firmest foundation of the growth of Russia. The Esthonian and Livonian F. fared worse, for they fell into the hands of German nobles, who treated them as serfs. Of all the F. races, the Magyars alone attained autonomy, and that not in their native country of the Ural Hills, but in Hungary, which had a political existence before they conquered it. Generally speaking, all the other F. tribes have become scattered among greater peoples, but their dialects remain as oases of speech, though the races themselves are but fragments of what they once were. Their name has been applied with some confusion. By Norwegians it is often given to the 17,000 Lapps in Norway. Europe in general confers it only on the inhabitants of the Grand Duchy of Finland. Ethnologically, it is used of the whole class of which the F. and Lapps are members, but philologists would now denote this class by the Russian name *Chudic*, or the also Russian *Ugric*. The latter seems preferable, from its connection with the name *Ungarn* (Hungary), used in the middle ages to denote a great province in the N.E. of Europe and W. of Asia. The following list comprises the different peoples who speak these F. (Ugric, Chudic) tongues with their populations according to the latest authorities :—

			Inhab.
I.	Transuralian F. (in the valley of the Obi)—		
	1.	Woguls	6,500
	2.	Ostiaks	25,000
II.	Permic F. (Bjarmians), chiefly in the governments of Perm, Viatka, Vologda, Archangel, &c.—		
	3.	Permians,	75,000
	4.	Siryanians	120,000
	5.	Wotiaks	214,000
III.	Volga F. (between Perm and Orenburg)—		
	6.	Cheremissians	200,000
	7.	Mordwins	780,000
IV.	Baltic F.—		
	8.	F. in Finland	1,600,000
		F. in St. Petersburg (government), Olonetz, &c., in Norway and Sweden	200,000
	9.	Esthonians and Livonians	635,000
V.	10.	Lapps in Norway, Sweden, and Russia	24,000
VI.	11.	Magyars in Hungary and Transylvania	4,820,000
		Total	8,699,500

Fins (allied to the Lat. *pinna* or *penna*, 'a feather'), the structures found typically in fishes, and which are adapted for locomotion in water. They are also found in certain mammals, as in whales and *Sirenia* (q. v.), the former having in some instances (see FINNER WHALE) a back or dorsal fin, and the latter a tail-fin. The pectoral or breast fins of fishes correspond to the fore-limbs, and the ventral fins to the hind-limbs, of other *Vertebrata*. The dorsal, anal, and caudal fins have no correspondence or homology with limbs, but are to be regarded as special developments of the skin in the middle line of the body. The swimming paddles of seals, walruses, &c., correspond to the pectoral fins of fishes, and represent the fore-limbs modified for locomotion in water.

Fins'bury ('fen town'), a parliamentary borough of Middlesex in the northern district of London (q. v.), returns two members. Pop. (1871) 452,484.

Fin'scale. See RED EYE.

Finsteraar'horn (Ger. 'the horn of the dark Aar'), so called because the dark Aar rises from it, the highest peak in the Bernese Alps, 14,000 feet high.

Fin'sterwalde (Ger. 'dark wood'), a town in the province of Brandenburg, Prussia, 40 miles N. of Dresden, with manufactures of linen, cotton, and flannel. Pop. (1871) 7289.

Fi'orin. See BENT GRASS.

Fir (Old Eng. *furh*, comp. Ger. *föhre* and Welsh *pyr*), a name given generally to many species of trees belonging to the natural order *Coniferæ* (q. v.). It may be botanically restricted to the species of the genus *Abies*, which also include the Spruce (q. v.); but many pines (*Pinus*) are also so denominated—the Scotch F. (*P. sylvestris*) being one of the most familiar examples. In the genus *Abies* the leaves are arranged singly, and are flat, whilst the scales of the cones are deciduous. Nearly allied to *Abies* is the genus *Picea*, or that represented by the silver firs, this latter genus having tetragonal leaves and persistent cone scales. Of the F. the Norway spruce or F. (*Abies excelsa*) is a good example. This tree attains a height of from 100 to 180 feet, and has an erect stem, whilst its branches are given off in the markedly symmetrical manner characteristic of these trees as a whole. It grows in Northern Europe, Asia, and even in the Arctic circle, and lives about 400 years. It yields *common frankincense* or *Thus*, and paper has been manufactured from its wood. Like most other species of F., it also yields resin, turpentine, tar, &c. The wood is very durable, and is known as *Danzig deal* and *white Christiania deal*. The soft sapwood is occasionally eaten in Sweden. Other species belonging to the genus *Abies* are the *A. balsamea* (the balm of Gilead fir) and *A. Canadensis*, from which 'Canada balsam' is obtained. The leaves of the latter, which is known as hemlock spruce, and also those of the *A. nigra*, yield the extract used in spruce beer. *A. pectinata*, the silver F., affords Strasburg turpentine. The white spruce (*A. alba*) is very common in N. America. *A. Douglasii*, the giant pine of California, thrives in Britain, and may attain a height of 245 feet with a circumference of 57½ feet at a height of 3 feet from the ground. To the genus *Pinus* belongs the typical Scotch F. (*P. sylvestris*), a tall tree with evergreen aciculate or needle-like leaves, naked flowers, and a cone or multiple fruit. The male flowers of the Scotch F. are arranged in short catkins composed of small overlapping scales, each scale having two anther lobes on its lower surface. The female flowers are in small dense catkins, each scale of which has at the base of its upper side two inverted seeds or ovules. The ovules are not enclosed in any seed vessel, and the F. and other Conifers are thus named Gymnospermous or naked-seeded plants. The Scotch F., the only pine now native in Britain, furnishes the wood known as yellow deal. Tar is distilled from it, and pitch is the residuum after the distillation of the liquid part of the tar. The inner bark of the Scotch F. yields the 'bark bread' of Norway. The firs, which are of Arctic type, flourish under conditions which would be fatal to the growth of other trees of their size. See PINE.

Fir Bholg, signifying 'men of the quiver,' a name given to one of the various tribes who invaded Ireland in prehistoric times. The S. of Ireland is sometimes called Bolga, and it is sought to identify the people with the Belgæ.

Firdu'si, Firdousi or **Firdewsi, Abou'l-Casim Mansur**, a great Persian poet, was born at Schadab, near Tus in Khorassan, in 940. He was called F. ('paradise') either from his father being in charge of an estate named F., or from the Sultan Mahmud saying that his poems were a true 'paradise.' F. early determined to frame an epic on the history of Persia; visited the court of the Sultan Mahmud at Ghuznee, then a famous seat of letters; and at Mahmud's request undertook to write an epic on the Persian kings from mythical times down to the 7th c., the sultan promising him a gold dirhem for each couplet. The work is said to have occupied F. for thirty years, and on its completion, Mahmud, prejudiced against F. by the poet's enemies, sent him 60,000 dirhems of silver, instead of the gold coins which he had promised. In return F. bitterly satirised Mahmud, whose resentment compelled him to wander from court to court, seeking protection which the various monarchs dared not bestow. F. seems to have died in his native place, about 1020. His life, and especially his latter years, are shrouded in legends, the stories regarding him being often very contradictory. F.'s great work, the *Shah-Nameh* ('Book of Kings'), is said to have at first contained 60,000 couplets, but no extant MS. comprises more than 56,685. The poem deals with mingled fable and history, and embraces 3600 years. It has no epical unity, being divided into separate tales, to each of which an introduction and epilogue are affixed. The chief theme is the war of Iran (Persia) with Turan (Turkestan). In the East it is regarded as of great historical value, but the only reliable portion seems to be that devoted to the Sassanids. It is one of the most interesting philological relics in Persian, is pure, though archaic, in style, with very few Arabic words. Sir William Jones says if it were understood in the original, it would 'contest the merit of invention with Homer himself.' It abounds in rich, daring, and often fantastic Oriental imagery, contains many fine passages of lofty and pathetic poetry, and its verse is softly

musical. The *Shah-Nameh* was published at Calcutta in 1829, edited by Turner Macan, and at Paris in 1840, with a translation and commentary by Mohl. See Hammer's *Gesch. der schönen Redekunste Persiens*, and the biographies in Macan's and Mohl's editions.

Fire-Anni'hilator, a portable machine designed to extinguish fire by forcibly ejecting upon the burning mass a saturated solution of a gas or of other substances incapable of supporting combustion. The French call such a machine *l'extincteur*, a name which has been adopted by inventors in Great Britain. Mr. Phillips's F.-A. (1849), contrived to project steam, carbonic acid, and other gases, has not been much used. In 1873 Mr. W. B. Dick, of Glasgow, patented an extincteur, which consisted of a cylindrical vessel containing water saturated with bicarbonate of soda in the lower part, and in the upper of a bottle filled with sulphuric acid. The bottle may be readily broken by percussion applied to an external cap, and the ensuing chemical action of the acid on the bicarbonate produces carbonic acid, which by its own expansion is propelled through a stop and delivery hose as a super-saturated aqueous solution. Many public buildings, ships, &c., are provided with this extincteur. A novel and ingenious plan of extinguishing fires in buildings where steam power is used was patented in 1875 by Mr. Henry Lacy of Hebden Bridge, Yorkshire. His method is to connect a branch pipe, which may be carried to any part of the building with hose attached, to the water-supply pipe leading through an injector to the boiler of an engine. By means of stopcocks, the water is cut off from the boiler; and steam, being admitted into the injector, drives the water along the branch pipe with a force regulated by the pressure of steam. Provision is also made for mixing chemicals with the water in the branch pipe.

Fire'arms. The discovery of Gunpowder (q. v.) and its application to purposes of war led soon to the disuse of the old weapons of attack. The earliest form of goune (*canna*), or 'crake of war,' was probably an iron pot or 'mortar.' A specimen capable of throwing 160-lb. shot is preserved in the Rotunda at Woolwich. This gradually changed into a cylinder form, which may have been suggested by the practice of throwing 'feathered quarrels.' The early Cannon (q. v.) of the 14th c. were made of wrought-iron bars bound by iron girders, the shot used being generally stones. The larger cannon, Froissart's *grande artillerie*, subsequently called *bombardes*, of which Mons Meg at Edinburgh Castle is a specimen, projected granite balls. Some of these were breechloaders, and the largest could throw 200 lbs. It is said the Dulle Griette or Margot la Folle of Ghent, and Mahemet II.'s gun at Constantinople, now in the Woolwich Artillery Museum, threw each 600 lbs. In the 15th c. appear primitive *mitrailleuses*, called by the Germans 'death-organs,' and the lighter pieces for field-work with trunnions mounted on carriages with trails. At the end of the 15th c. hand-guns called culverins were used, two men for each; smaller petronels being supplied to the cavalry. Gustavus Adolphus (1630) first introduced small iron cannon for field purposes. In the middle of the 16th c. Henri II. of France had cannon of 34 lbs., culverins from 15 lbs. to 2 lbs., and falcons and falconets which threw small shot of 1 lb. and ½ lb. Grooved or rifled cannon (see RIFLED ARMS) occur in the 17th c., so that Benjamin Robins, who lived in the following century, was not the author of the idea. The long harquebus, and the longer and heavier muschite, or sparrow-hawk, which was fired from a rest, were both of Spanish origin. The old matchlock gradually gave place to the clumsy wheel-lock of Nürnberg and the snaphaunces, but not till about 1692 did the developed flintlock entirely supersede the matchlock. Casting guns was introduced to England by Sebastiani, under the patronage of Henry VIII.; many of the brass 'sakers' of that period still survive. The petard of this period was a kind of iron mortar, like a truncated cone, filled with gunpowder and yellow wax, or Greek fire. It was used for blowing up gates and bridges. There was a separate tube to carry the lighted match. Bombs were known in England in the 16th c. Ricochet-firing was first tried by Vauban at Philipsbourg in 1688. The bar-and-chain shot used in naval warfare were generally fired out of the guns called 'murtherers.' Many forms of hand-F. we have not yet mentioned. The iron hand-cannon, with a small pan under the right side to hold the powder, passed into the hand-gun proper cast in brass, the first step towards the gunlock. The *arquebus-à-croc*, or with a hook, was fired from a tripod, and therefore is not properly a hand-arm. The smaller haquebut, or hagbut, had a hooked or crooked stock, which gave greater facilities for aiming than the straight barrel. The demi-haque was merely a long pistol, with a semicircular butt. The musket (literally the male young of the sparrow-hawk), perhaps so called from mousquette, or muschetta, the iron part of the small arrows fired from guns, has been referred to a Russian as well as a Spanish origin. It was first largely used by Alva. The ramrod was called 'a scouring stick' or 'scorier;' and indeed wooden ramrods were used in the British army down to 1752. The so-called Vauban lock (really much older) was an attempt to combine the action of a flint and steel with that of a match-cord. The caliver was a short musket fired by a matchlock without rest. The name really refers to the calibre or bore—the height of the bullet—and marks the important change that all the men of a regiment must use the same ammunitions. The Fusil (q. v.) was a short musket (flintlock) used by the French army from 1700; it was fired not from the breast, but the shoulder. The Carbine (q. v.) was a wheel-locked arquebus of large calibre used by skirmishers in the French army (1576 to 1665) and by the English cavalry at the end of the 17th c. The currier was longer in barrel than the arquebus, but not of so wide a bore; it was used chiefly in sieges. The musquetoon was a smaller sort of musquet, not so long as the fusil, but differing from the carbine in having a firelock, and not a wheel-lock. The Pistol (q. v.) was an arquebus in miniature, and fired by the wheel-lock. It was much used by the German Reiters, and in one form with a snaphaunce lock in the Scotch Highlands. The dag was simply a pistol with a crooked stock. The petronel or petrinal (from *poitrine*, 'breast,' from which it was fired) was a sort of arquebus, shorter than the musquet, but of larger bore, in fact very like the modern carbine. The Blunderbuss (q. v.) was very short, with a wide bore, and was charged with several balls or slugs. The dragon (see DRAGOON) was a formidable small form of the blunderbuss; it was conveniently carried on horseback, and effectively used on foot. The hand-mortar was used for throwing shells or Grenades (q. v.). The patent of Forsyth for a percussion gun (1807) was followed in 1827 by Dreyse's invention of the needle-gun, which in 1836 was converted into a breechloader. In the Minie rifle the charge in exploding expands the end of the bullet, a result formerly obtained by the pressure of the ramrod, or more anciently in the rifled harquebus by a mallet. The chief forms of the needle-gun besides the Prussian are the Chassepot, the Snider, the Peabody (Swiss), the Werndl (Austrian), and the Remington (Danish). (See BREECHLOADING ARMS.) The recent improvements in large ordnance are noticed under CANNON. Among great collections of F. may be mentioned those of Dresden and the Musée d'Artillerie at Paris. Birmingham recently started one, which received help from the Government. The only large private collection in this country was that of Meyrich at Goodrich Court. See Louis Napoleon, *Études sur le Passé et l'Avenir de l'Artillerie;* Grose, *Military Antiquities;* Scott's *British Army*, vol. ii.

Firearms, Law Regarding. Before firearms are sold they must be tested in a public proof-house. The statute does not extend to Scotland or Ireland, and arms manufactured for the Queen are exempted. An Act granting a duty of excise in licenses to use guns was passed 9th August 1870.

Fire'balls, hollow projectiles filled with gunpowder, sulphur, naphtha, and similar combustibles, and discharged from cannon to illuminate or ignite an enemy's work. Rockets have greatly superseded their use.

Fire'bote, in English law, is the right of a tenant to cut wood for fuel on the ground held by him. See ESTOVER.

Fire'brick. See BRICK.

Fire-Brigade'. In London almost the whole of the fire-engines are under the control of the insurance companies. Up to 1825 each company had its own brigade; but in that year some of the principal associations joined together, and the advantages of conjoint action soon became so obvious that by 1833 nearly all the remaining companies had merged their establishments in the central one, and the present Metropolitan F.-B. was formed.

The skill and bravery of its men and excellency of its organisation have earned for it since its formation great popularity. In London each parish has under its own management a separate fire-engine. These machines are very small, and of little use in comparison with those of the brigade. In Edinburgh and most other cities the fire-engines belong to the municipal authorities, under whose control also the brigade is. On the Continent the fire establishment is generally under Government control; in America there are in most cities companies of volunteer firemen, who have certain immunities from taxation and militia service in lieu of pay.

Fire'clay is so named from its fire-resisting nature, which arises from the predominance of silica together with the small percentage of fluxes in its constitution. Pure F. is composed of silica, alumina, and water; but an alkali, lime, magnesia, or iron oxide is always present in variable proportions, tending to give fusibility to the clay. F. with over one per cent. of alkalies is unable to withstand very high temperatures for a prolonged period, but oxide of iron alone, to the extent of four per cent., is not detrimental. In Great Britain it is chiefly found in the coal measures, in beds of from 1 foot to 4 feet in thickness, forming the under clay of the coal seams. Valuable deposits occur at Stourbridge in Worcestershire, Garnkirk and other places in Lanarkshire, at Lilly Hill in Fifeshire, and at Blaydon on the Tyne. Stourbridge is the most celebrated of the British fireclays, and has the following percentage composition:—Silica, 63·30; alumina, 23·30; lime, 0·73; oxide of iron, 1·80; water, 10·30, with traces of titanic acid and carbonaceous matter. Gas retorts, glass-house pots, crucibles, furnace bricks, glazed drainage pipes, terra-cotta ornaments, and many other articles are made of F. When excavated, it is exposed to the disintegrating action of the weather; it is afterwards pulverised, mixed with water, kneaded in a pug-mill, then moulded by hand, and carefully dried and fired.

Fire'damp, an explosive mixture of Marsh Gas (q. v.) and air, is of frequent occurrence, and a source of great danger, in coal-mines. See SAFETY-LAMP.

Fire-Eating. Conjurors have at different times professed their ability to eat fire with impunity. Richardson, an Englishman, who travelled over Europe in the 17th c., chewed burning coals, poured melted lead upon his tongue, drank molten glass, and held red-hot iron in his mouth. Sir David Brewster (*Letters on Natural Magic*), commenting on these and similar performances, says, 'That these effects are produced partly by deception and partly by a previous preparation of the parts subjected to the heat, can scarcely admit of a doubt. The fusible metal—composed of mercury, bismuth, and tin, which melt at a low temperature—might easily have been substituted in place of lead, and fluids of easy ebullition may have been used in place of boiling water.' The skin becomes horny, and therefore insensible to intense heat, by continually compressing, singeing, or pricking it, or by frequently washing it with dilute sulphuric acid. Mediæval priests were acquainted with other protective preparations, which enabled them to pass 'the innocent' through the ordeal of fire with impunity.

Fire'-Engine, a pumping-machine for extinguishing fires. A double pump apparently for this purpose is described by Hero of Alexandria (B.C. 284-221), who calls it 'the syphons used at conflagrations.' There are now no means of saying how far such a machine (which was in principle identical with those employed at present) was used in the time of its inventor. We first hear of fire-engines definitely during the latter half of the 17th c., when they appear in very much the same form as that described by Hero. Up to this time huge squirts containing a few quarts of water were the principal means of extinguishing fires in this country. Two men held one of them, and a third pressed the piston upwards. The first F.-E. of which we have a trustworthy account was made at Nürnberg by Hautsch, and is described by Gaspar Schott in 1657. It carried its own water cistern, was worked by twenty-eight men, and seems to have had a kind of flexible discharge pipe. The general use of the leathern hose dates only from about 1670, when two brothers Van der Heide (fire-inspectors) introduced them at Amsterdam and obtained for them patent rights. Since then they have been universally employed, first of leather sewed, then riveted, and later of canvas and india-rubber, and of india-rubber alone. The first use of the *air vessel*, now an essential part of all fire-engines, is ascribed to a Frenchman, Perrault, in 1684. Subsequent improvements in the F.-E. down to 1830 were chiefly in details. In that year the first steam F.-E. was used by Mr. Braithwaite, who shortly afterwards brought out a more powerful one, and constructed also a *floating* steam F.-E. The use of steam did not make much progress at the time, and it was not until 1861 that Messrs. Shand & Mason made the first steam F.-E. used by the London Brigade. Since that time the steam F.-E. has become more and more important, there being few important towns without one or more. One of the largest kinds used weighs about 23 cwt., and can send a jet to a vertical height of 180 feet. These engines are specially constructed so that steam may be raised quickly—in the one just mentioned steam of 100 lbs. pressure per square inch can be obtained seven minutes after the fire is lit; of course this process may be going on as the engine is being driven to the fire, so that no time is lost. The modern F.-E. consists of one or more force-pumps (see PUMP), delivering water into an air chamber communicating with the discharge pipe and hose. By their action the air in the chamber is kept constantly compressed to any desired extent, and reacting by its elasticity upon the water, it forces it out in a continuous stream.

Fire-Escape', an apparatus for enabling persons in burning houses or buildings to escape. The name is strictly applied to a ladder 30 or 35 feet high, with a canvas trough behind it, and smaller sliding ladders attached to it, by which its length can be increased to 45 or 50 feet, and in some cases even more. The whole is supported in a nearly vertical position on two large wheels, so that it can readily be moved. In London there are about 120 fire-escapes, so placed that almost any house can be reached by one of them in five minutes. They belong to the 'Society for the Protection of Life from Fire,' an association founded in 1836, and supported by voluntary contributions. In our cities, where so many houses have only one narrow stair, communication by which sometimes becomes impossible at the very beginning of a fire, they have saved very many lives.

Fire-Fish, the name given to certain Teleostean fishes from their brilliant colouration. The best-known species is the red F.-F. (*Pterois volitans*) of tropical seas, which belongs to the family *Triglidæ* or gurnards. The body is scaly, and has many spines and rays. The dorsal and pectoral fins are especially large, and their rays are prominent. The colour is a pinky brown with dark-brown markings. The average length is 8 or 9 inches. The flesh is eaten on the Ceylon coasts.

Firefly, a name sometimes applied generally to insects with phosphorescent or luminous properties, but restricted in a zoological sense to such forms as the Cucujo or F. of Brazil (*Pyrophorus luminosus*), the glow-worm (*Lampyris noctiluca*), and allied forms. The former insect belongs to the family *Elateridæ* of the *Coleoptera* or Beetle order of insects, and the latter is also a beetle belonging to the family *Lampyridæ*. The F. of Brazil is very luminous, the light proceeding from two spots at the base of the thorax, whilst two other shining patches exist beneath the wing-covers. These insects fly by night, and render the forests bright with their luminosity. Various other species are known. The glow-worm is familiar to all as a luminous insect or F. The females exhibit the utmost brilliance. The female glow-worm is wingless, the male being winged and of brown colour. Fireflies are most common in S. Europe and in tropical countries. How the luminosity is produced is still undetermined in an exact sense, but there appears to be little doubt that it is developed by the nerve-force acting through some special apparatus. See also LUMINOSITY and PHOSPHORESCENCE OF ANIMALS.

Fire Insu'rance, Law Regarding. When there has been damage by fire, notice should at once be given to the office, and an account given on oath or affirmation of the loss. Account-books and other vouchers should be shown in support of the account. It is well also to procure a certificate from the clergyman, and one or two others of position in the parish, not concerned in the loss, stating that they are well acquainted with the sufferer, and that they believe him to have sustained the damage alleged. To whatever amount persons insure, they can only recover the value of the loss sustained. A house being

insured for £19,000 was totally destroyed by fire, but the company, though the premium on £19,000 had been paid for many years, refused to pay more than £12,000, alleging that this was ample value. If a policy be effected in several offices on the same subject, they are only liable proportionally to make good the loss. However small the damage to the subject insured, the office is liable; for example, under a policy on furniture, the office is liable for damage by a hot cinder. Most offices pay for damage caused by lightning or gas explosion, but the insurer should inquire as to this.

Firelock, the name given in the 16th c. to a musket or pistol with a wheel-lock, and afterwards to the musket with a flintlock, which in 1690 was introduced in place of the earlier matchlock. See FIREARMS.

Fire, Malicious Injuries by. See EXPLOSIVES.

Firenzuola, Agnolo, an Italian scholar and writer of fiction was born at Florence, September 28, 1493. He studied law at Siena and Perugia, but, while young, became a monk, and in 1525 was made abbot of a monastery at Spoleto. He was a friend of Aretin, is said to have led a profligate life, and died at Prato about 1545. His chief works are a free adaptation of the *Golden Ass* of Apuleius, *Apuleio, Dell' Asino d' Oro tradotto per Agnolo F.*, which excels the original in beauty of language; *Discorsi degli Animali*, partly imitations of Æsop; *Ragionamenti Amorosi, Novelli Otto*, licentious, sportive tales in the choicest Tuscan; *Dialogo delle Bellezze delle Donne;* two comedies, some satirical verses, &c. F. is one of the masters of Italian prose. His language is clear, flowing, and full of colour. See the Life in the edition of F.'s works published at Florence in 1848, and Maffei's *Storia della Letteratura Italiana* (Flor. 1853).

Fire-Proof Buildings. A building is fire-proof only when, in the event of a fire in one compartment, the fire burns itself out there without communicating with another compartment, or endangering the building. Considerable attention has been given to fire-proof construction, yet we have not made much progress in the art. Many buildings believed to be fire-proof, because in their construction brick, concrete, and iron are abundantly used, and wood very sparingly, when subjected to the fiery ordeal, assuredly succumb. The destruction of the London Pantechnicon in February 1874 is a case in point. Though constructed on the most approved principles, it was wholly consumed in a few hours. That conflagration proved the weakness of iron pillars as supports to brick arches, for they melted with the intense heat, or cracked when water was thrown upon them. Absolute fire-proof construction can only be attained at a great sacrifice of space. The compartments should be small, with thick firebrick walls supporting groined firebrick roofs. Where large floor areas are required, brick pillars should support the groined roofs. For valuable information on F.-P. B. see the *Transactions of the Society of Arts.*

Fire-Proofing, the art of diminishing the destructive effects of fire on inflammable materials. Textile fabrics are rendered non-inflammable by steeping them in any inorganic saline solution, whereby the fibres are coated with a protective crust that absorbs heat and excludes air. Fabrics so treated smoulder slowly when exposed to a high temperature, but do not burst into flame. For F.-P. light fabrics, phosphate of ammonium, alone or mixed with chloride of ammonium, sulphate of ammonium, or tungstate of sodium is recommended. The last named is most used for goods that require to be ironed. Little success has attended the efforts made to fix the protective agents in the fibre, by rendering the saline crust insoluble in water. Fireproof clothing may be made with the fibrous mineral asbestos. The ancients were acquainted with the art of weaving it into garments. About the year 1828, Chevalier Aldini of Milan advocated its use for firemen's dress, in combination with cloth steeped in alum, and with wire-gauze. Wood is rendered incombustible, or nearly so, by painting it with silicate of soda, or by impregnating it with an aqueous solution of alum and sulphate of copper, or of common salt and alum. A new mode of F.-P. wood has recently been devised. Sulphate of zinc (2½ parts by weight), American potash (1 part), ammonium alum (2 parts), oxide of manganese (1 part), are mixed in a boiler, and water (2½ parts), at a temperature of 113° F., is run in. When the solution is effected, sulphuric acid (1 part), at 60°, is gradually introduced. The wood for F.-P. is submitted for three hours to the action of the solution, which is maintained in a state of ebullition during that time.

Fire-Proof Safes and other depositories. See SAFES.

Fire-Raising is in Scotch law the equivalent term to Arson (q. v.) in England. To constitute the crime there must have been actual burning, but it does not matter how small a portion of the subject has been consumed Ignition of furniture alone, when not a fixture (see FIXTURES) of a building, makes the culprit liable to a charge of an attempt at F.-R. Setting fire to one's own house, if so doing is not dangerous to the property of another, and if the act is not fraudulent, is not indictable. To set on fire growing crops, or to attempt to do so, is felony by statute. See EXPLOSIVE MIXTURES; GUNPOWDER, LAW REGARDING.

Fireship, a vessel laden with combustible matters, which in maritime warfare was sailed into an enemy's fleet, set on fire, and abandoned, in the hope that it might do damage or create confusion. The F. is of very early origin; we hear of its employment more than 2000 years ago. It is not used in modern warfare by civilised nations, although the Chinese employed fireships unsuccessfully against the British fleet before Canton in 1857.

Fireworks and Squibs. See PYROTECHNY, EXPLOSIVES.

Fire-Worshippers. See GUEBRES.

Fir'kin (Old Eng. *feower*, 'four'—Dan. *fire*—and dim. *kin*), the fourth part of a barrel, equal to seven and a half imperial gallons.

Fir'lot (Old Eng. *feower*, 'four'—Dan. *fire*—and Eng. *lot*, 'part or portion'), a dry measure Scots, equal to the fourth part of a Boll (q. v.).

Firm. See PARTNERSHIP.

Fir'mament is the Latin word (*firmamentum*) in the Vulgate for the Greek *stereōma* of the LXX. and the Hebrew *rakia* in Gen. i. 6, 7, &c. The literal meaning of the Hebrew word seems to be a thin solid plate which has been hammered out. Similar names for the sky, scientifically incorrect, but expressing its actual appearance, are found in other languages—Gr. *ouranos*, Eng. *heaven*, 'that which is elevated;' Gr. *koilon*, Lat. *cælum*, 'the hollow place;' Ger. *heimeln*, 'a roof.' The Hebrew F., which was supported as if on pillars by mountains (2 Sam. xxii. 8; Job xxvi. 11), served a twofold purpose—first, of supporting a reservoir of water (Gen. i. 7; *cf.* Ps. civ. 3, cxlviii. 4), which descended as rain through windows (Gen. vii. 11, viii. 2; Mal. iii. 10) and doors (Ps. lxxviii. 23); secondly, of supporting the heavenly bodies—sun, moon, and stars (Gen. i. 15). According to the Christian fathers who commented on Genesis, as late at least as the Venerable Bede (8th c.), the earth was a flat plain skirted by mountains, on which the F. was supported like a dome, or stretched like a skin. In short, the fixity of the F. was necessarily combined with the flatness of the earth, a belief in which prevailed till the end of the 15th c., when the attempt of Columbus to prove its rotundity was condemned as irreligious by the Council of Salamanca. See Draper's *Conflict between Religion and Science* (International Science Series, 1875).

Fir'man (Pers. *ferman*, 'a command'), the official mandate of an Oriental sovereign, and especially of the Ottoman Porte. It also signifies the passport given to a traveller in the Turkish empire, and in India denotes a certificate giving permission to trade.

Firminy, a town in the department of Loire, France, 39 miles S.W. of Lyon by railway. It is surrounded by extensive coal-mines and stone-quarries. Pop. (1872) 8873.

Firola, a genus of Gasteropodous Molluscs belonging to the aberrant group *Heteropoda* or *Nudibranchiata*, in which the 'foot' of other *Gasteropoda* is modified to a flattened fin-like organ, used for swimming, the animals generally moving back-downwards through the water. The shell, at most rudimentary in the *Heteropoda*, is wanting in F. The genus gives the name to the family *Firolidæ*, in which a large body exists, and locomotion is performed by the modified foot, and by a tail-fin in addition. The body in F. is 4 or 5 inches long.

First'-Born. By the common instincts of human nature, which prompt parents to give their affection most fully to their F.-B., pre-eminent importance and privileges have always been granted to the eldest son in a family. According to the laws of most nations he succeeded to the official position and authority of his father, and for the same reason, as well as to enable him to sustain that dignity, received a larger share than his brothers of his father's wealth. According to the Mosaic law he inherited 'a double portion,' *i.e.*, twice as much as any of the other sons (Deut. xxi. 15-17). With the Hebrews, also, a special sanctity attached to the F.-B. both of man and beast, as devoted to the Lord in commemoration of the F.-B. of the Israelites being spared when those of the Egyptians were cut off. (See PASSOVER.) Of the animals, the clean (see Lev. xi.), if free from blemish, were offered in sacrifice (Deut. xv. 21); the unclean, not being fit for sacrifice, were to be put to death, to be sold, and the price given to the priest, or to be redeemed by the owner with a lamb or with six-fifths of its value (Exod. xiii. 13; Lev. xxvii. 11-13, 27). The F.-B. of man were all devoted to the Lord to be priests; but as they were superseded in this office by the Levites (q. v.), it was ordained that the F.-B. of the other tribes should be redeemed (Num. iii. 11-13, 40 46, xviii. 15).

First-Born, Law Regarding. See PRIMOGENITURE, HEIR, SUCCESSION.

First-Fruits. It was a common practice in ancient times to make an offering to the gods of the first of the fruits of the ground that were ripe, as an acknowledgment of their bounty in the past, and to procure from them good crops in the future. Such offerings were made by the Egyptians to Isis, by the Greeks to Demeter, Apollo, and Diana, and by the Romans to Ceres and Bacchus. Among the Hebrews, too, it was appointed by the Mosaic law not only that the first of all the produce of the ground should be offered to Jehovah, but also the first-born both of man and beast (Exod. xxii. 29, 30; Deut. xxvi. 2-11. (See FIRST-BORN.) Special occasions for the offering of F.-F. were—(1) At the Feast of the Passover, when the first sheaf of the harvest was brought to the priest, and by him waved before the Lord (Lev. xxiii. 5-12; (2) at the Feast of Pentecost, when a similar offering was made of two loaves of bread made from the new flour (Lev. xxiii. 15-17). Besides these public or national offerings, private offerings were to be made of the first-thrashed grain, of a cake of the first-ground meal (Num. xv. 17-21), of the best of the wine and the oil (Num. xviii. 12, 13), and in short, 'of all the fruit of the earth' (Deut. xxvi. 2). All these offerings fell to the priests, as part of their living (Deut. xviii. 3-5). The amount to be given as F.-F. was not fixed by the Levitical law; in the Mishna the minimum was fixed at one-sixtieth.

In the Christian Church the practice of dedicating F.-F. to God for the support of his servants was observed from an early period. At first the fathers represented the practice merely as becoming and expedient; but as the notion grew that the clergy had succeeded to the position and privileges of the Levites, the Levitical law on this matter was represented as binding on Christians, for which conclusive proof was found in Mal. iii. Full details on the subject are given in the *Apostolic Canons* and *Constitutions*. A species of F.-F. was lat'erly exacted from the clergy themselves by the popes. (See ANNATES.) See Spencer *De Legibus Hebræorum* (2d ed. Hag. 1686), and Smith's *Dict. of Christ. Antiquities* (1875).

Firth or **Frith** (Dan. and Norw. *fjord*, Sw. *fjärd*), an arm of the sea or the estuary of a river—a word in common use in Scotland, as the Moray F., the Firths of Clyde, Forth, Tay, &c.

Fischart', Johann, a German satirist, was born at Strasburg between 1545-50, studied law at Basel, visited England, lived as an advocate at Speier and as a bailiff at Forbach, where he died in 1589. F. was a man of considerable learning and great comic genius. He replied to the abusive attacks on Luther, which were common in his time, by fierce and telling satires and burlesques, full of rich, gross Aristophanic humour, and showing a marvellous command of language. Among his works are *Geschichtklitterung der Thaten der Helden Gargantua und Pantagruel* (1575), partly translated, partly imitated, from Rabelais; *Das Glückhafft-Schiff von Zürich* (1576); *Flöhatz Weibertratz* (1574); *Die zehn Alter der Wieber; Aller Praktik Grossmutter; Podagrammisch Trostbüchlein;* and *Psalmen und geistliche Lieder* (1576; new ed. Berl. 1849), which contain many fine sacred poems. A collected edition of F.'s poems was published by Kurz in 3 vols. (1866-68). See Wackernagel's *J. F.* (1870).

Fish, or **Fish-Plate,** a piece of wood or metal used in joining together the abutting ends of two members of a structure. The most familiar *fished joint* is that employed almost universally for connecting rails. Here the ends of the rails are made almost to touch, a F.-P. 15 to 18 inches long is placed upon each side of them, and the whole secured by two or three bolts through each rail. The importance of a sufficiently rigid rail-fastening is very great, not only on account of the increased comfort which it gives to travellers, owing to the smoothness of motion which it secures, but also because it greatly lessens the wear and tear of the rolling stock. Engineers have given much attention to the form and proportions of fish plates and joints with the view of finding out the best possible arrangement, and many patents have been taken out in connection with them. Fished joints are used also for timber ties and beams, for strengthening spring spars, and many other purposes.

Fish'er, John, Bishop of Rochester, was born at Beverley in Yorkshire about 1459, and after a distinguished college career at Cambridge, became Master of Michael House College in that university in 1495. As confessor to Margaret, Countess of Richmond, the mother of Henry VII., he induced her to found St. John's and Christ's Colleges. But for the Reformation F. would probably have had a peaceful and prosperous career. In 1501 he was chosen Chancellor of the University; in 1504 he became Bishop of Rochester. At first he was the favourite champion of Henry VIII., and wrote for him the pamphlet *Assertio Septem Sacramentorum*, for which that king obtained the title of 'Defender of the Faith.' But in 1527 he objected to the divorce of Queen Catherine, refused to acknowledge the legality of Henry's marriage with Anne Boleyn, and opposed Thomas Cromwell's scheme for the suppression of the monasteries. He was thrown into prison and released on paying a fine of £300; but in 1534, on refusing to acknowledge the king's supremacy in the Church, he was committed to the Tower, and his bishopric declared vacant. Pope Paul III. sent him a cardinal's hat as a consolation and mark of respect, but Henry brutally declared that F. would have to wear it on his shoulders, for he would not leave him a head. After a short trial for treason, the old man was beheaded, June 22, 1535. A biography of F., who was a writer of Scriptural commentaries, sermons, and controversial pamphlets, has been written by Lewis (2 vols. 1854).

Fish'eries. Under this term are generally included all the industries connected with procuring the creatures which inhabit either fresh or salt water, many of which have no connection with fish in their zoological relations. Thus the term includes the obtaining of such diverse animals and products as sponge, coral, pearl, shell-fish (including those valuable for their shells, as well as those sought for human food or as bait for other inhabitants of the sea), the crustaceans, as shrimps, crabs, and lobsters; and in the higher scale of animal life it is held to comprehend the capture of turtles, whales, seals, and their congeners. The only relation which these creatures bear to fish is the fact that they in common occupy the sea, and thus by F. are meant all animal products of the sea of whatever class. Here, however, will be noticed only the great industries for securing fish for human food from both salt and fresh water.

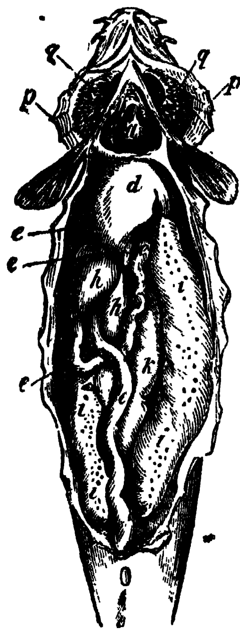
There is no way by which any approximately accurate estimate may be formed of the enormous value of the products annually drawn from the sea. Judging, however, by reliable statistics obtained for very limited areas, the wealth annually derived from the sea must be very great; and when the great extent of sea-board altogether neglected or only imperfectly fished is taken into account, there cannot be any doubt that F. are capable of indefinite expansion without crippling the productive resources of the sea. It is only in the case of a few minor creatures—noticeably the oyster, lobster, and crab on British coasts—that overfishing, or rather indiscriminate and wasteful habits of fishing, has resulted in any decline of productiveness, such as to call for legislative interference.

Fresh-Water Fisheries.—The one fresh-water fish of paramount

economic importance is the salmon, the F. of which in many Scottish rivers, particularly the Tay, are of very great value to their proprietors. While salmon fishing is the most prominent fresh-water industry, it is also highly esteemed for sport. It is prosecuted with draw nets, or in certain positions with stake nets; and by sportsmen the fish is taken with fly-hooks. The rivers of Northern Europe and America abound in salmon, and the produce of the American rivers now appears largely in commerce as 'tinned' salmon. The trout and other species of the salmon kind come next to the salmon in importance as fresh-water fish. After these may be reckoned the eel, pike, and perch; and in Russia, various species of sturgeon, obtained from the Volga and other rivers, are sources of valuable food delicacies, as well as of isinglass.

Sea Fisheries are of much greater economic importance than fresh-water F. They are prosecuted in a variety of ways, the chief of which are:—(1) Trawling, (2) drift-net fishing, (3) line fishing, (4) sean fishing, (5) bag-net fishing, (6) kettle nets and weirs, and (7) trammel or set nets. (1) Trawling is performed with a triangular bag which has an arrangement for keeping its mouth open. The apparatus is called a trawl, and it is drawn along the bottom of the water. It is much employed by English fishers for catching haddocks, soles, turbots, plaice, and flat fish generally. (2) Drift nets are long nets having a definite size of mesh, and they are shot from boats and allowed to depend perpendicularly in the water, the upper side being kept at the surface by cork floats. They are used chiefly for the herring, pilchard, and mackerel fishing, the shoals of which, meeting these barriers in their course, attempt to push through them and so get entangled by their gills in the meshes of the nets. It is essential for the success of this style of fishing that it be conducted at night. (3) Line fishing is of two kinds—long-line fishing, in which many hooks are attached to a long central line, and baited for catching cod, ling, halibut, and haddocks; and short or hand line fishing, in which only a single hook is employed for the capture of cod. (4) The sean or sweep net is a long length of netting which is used for enclosing and sweeping a certain area of water in much the same way as in salmon fishing. It is employed for catching herrings, sprats, pilchard, mackerel, and various small fishes. (5) Bag nets are large open-mouthed bags like great trawls, used for sprat and whitebait catching, &c. (6) Kettle nets and weirs are structures placed along the coast between high and low water with the view of entrapping fish which may enter with the flowing tide, and which are secured when the water recedes. (7) Trammel nets are like drift nets in their action, but are fixed between stakes or other stays. The Cornish trammel consists of three nets set parallel to each other, the two outer having wide meshes, while that in the centre is fine in the mesh. The fish, passing through the outer net, pushes against the central net, forcing part of it through a mesh of the opposite outer net, thus forming a bag or pocket in which it is itself securely fastened.

Of all sea F. none equals in importance, extent, and value the herring fishery. It is most extensively cultivated along the N. and E. coasts of Scotland, the principal stations being Fraserburgh, Peterhead, Wick, and Stornoway. The quantity of herrings taken annually on the Scottish coasts alone is prodigious, and there is good reason to conclude that the number taken by fishermen is but a fraction of what is destroyed by cod, dog-fish, sea-birds, and other natural enemies of the herring. Notwithstanding all these causes, there is not the slightest appearance of any decrease in the productiveness of the herring fishery, but quite the opposite. From annual returns which have been made by the Fishery Board of Scotland since 1809, it appears that, with many violent fluctuations, there has been on the whole a steady increase in the quantity of herrings cured yearly down to the present time. The largest cure reported during that lapse of time occurred in 1874, when 1,000,561 barrels were cured, which, allowing 750 herrings to each barrel, would give a total of more than 750,000,000 separate fish. The cure of 1875 stands second on the list with 942,980 barrels, and the only other year in which 900,000 barrels were exceeded was in 1873, when 939,233½ barrels were cured. These enormous numbers, it must be remembered, are exclusive of the incalculable quantity retailed throughout the country as fresh or as smoked herrings.



The Scottish Fishery Board also takes cognisance of the cod, ling, and hake fishing, which comes next in value to the herring industry. For these fishes the Shetland Islands are of more value than all the rest of Scotland together. The number returned as caught during 1875 was reported as 5,791,387 for the whole of Scotland, of which no less that 3,458,799 were taken on the Shetland stations. In 1875 there were cured dry 187,788½ cwt., and in pickle 8503½ cwt. were prepared. The fishing of 1875, judging by the weight of fish cured, was the most successful in the records of the Scottish Fishery Board. In 1873, 160,716½ cwt. were reported as cured, and in no other year did the total weight cured reach so high as 150,000 cwt. The extent of Scottish sea F. may be computed by the fact that in 1875 there were employed in the industry 14,655 boats of a total tonnage of 105,506 tons, with 45,082 men and boys. The F. gave direct employment to 89,221 persons; and in boats, nets, and lines the capital invested was estimated to amount to £1,092,275.

The principal markets for cured herrings are found in Germany and Russia, and the system of branding barrels by Government authorities greatly facilitates the disposal of cargoes. Five grades of brand are adopted, according to quality. 'Full crown' indicates fish containing roe and milt. 'Crown maties' are fat fish of smaller size than fulls, and the remaining grades of brand are 'crown spent,' 'crown mixed,' and 'crown repacked.' A fee of 4d. per barrel is charged for branding, and from this source £8729, 16s. 6d. was obtained in 1875. Dried cod, ling, and hake are principally disposed of in Spain. The Dutch and Scandinavians also prosecuted sea fishing very extensively, and the inhabitants of Iceland and the Faröe Islands depend very largely for subsistence and commerce on the cod and ling F., with, in Iceland, shark fishing, from which a valuable liver-oil is obtained. On the American coast, Newfoundland is the seat of the most valuable F., and there, in addition to enormous quantities of cod, the salmon, capelin, Labrador herring, mackerel, halibut, and turbot are obtained in great quantities.

Fishery, Free, is in England an exclusive right of fishing in a public stream. It is a royal franchise, and must be at least as old as the reign of Henry II., to grant the right being expressly prohibited by Magna Charta.

Fish'es, the lowest group of Vertebrate animals, are adapted for locomotion in water by being provided with gills for breathing, during the whole of life; by the heart consisting of an auricle and a ventricle; by possessing cold blood, which is carried in an arterial condition from the gills to the body; by the body being usually covered with scales; by the limbs being developed in the form of fins; and by the embryo possessing neither an Amnion (q. v.) nor an Allantois (q. v.). The *form* of F. is that best adapted for easy locomotion in water. In the great majority of cases the body is pointed at each end, and flattened somewhat from side to side, whilst it is also rounded on the sides. In some F. it is apparently flattened above and below—as in the flounder, plaice, and other 'flat-F.' But in these cases, the body is greatly flattened *from side to side*, the two eyes being through a peculiarity in development brought round to one side of the head. The skates, rays, &c., are more truly *flat-F.* than the flounders, &c., since their dorsal or back surface really appears to be flattened, owing chiefly to the great enlargement of the pectoral or breast fins. The bodies of most F. are scaly. In some cases (such as the eels), where scales are either very small or altogether wanting, the body is generally covered with a *mucous* secretion, serving to protect it from the action of the water. The scales of F. may be *cycloid*, as in herrings, salmon, &c.; *placoid*, as in skates and sharks; *ctenoid*, as in perches, &c.; or *ganoid*, as in the sturgeons, bony pikes, &c. This last form of scale is most common in fossil F. Along the sides of most F. a line named the *lateral line* may be perceived. This line was formerly believed to be connected with the production of the mucous secretion which protected the body or scales, but it is now ascertained to be connected with the exercise of the sense of *touch*, since the terminations of nerves have been traced to a connection with this line; and the acts of many F. in rubbing the sides of their bodies against foreign objects seem to lend support to this latter belief. The *endoskeleton* of F. may be of very varied nature. Thus in the lowest fish of all, the *Amphioxus* or lancelet, there is no skeleton to speak of, this structure being represented by a soft cellular rod, the *Notochord* (q. v.), or *chorda dorsalis*, which represents the immature and imperfectly-developed spine. In other F., such as sharks, skates, rays, the skeleton is imperfectly

ossified, and is composed of *cartilage;* whilst in the great majority, including the familiar food-F., it is of bony nature. The spine of F. (save in one instance, that of the bony pike or *Lepidosteus*) is composed of vertebræ, hollow at either end, and hence named *amphicœlous.* When two vertebræ are opposed, a cavity is formed by the opposition of the vertebral bodies; and this cavity forms a kind of universal joint, permitting the freest possible motion and movement of the spine in swimming. In the bony pike the vertebræ are *opisthocœlous,* that is, hollow behind and convex in front. The spine exhibits a division into two regions only—an *abdominal* and a *caudal* region, no distinct cervical, dorsal, or lumbar portions being recognisable. The vertebræ of the abdomen possess an upper or neural canal, neural spines, and two transverse processes, to which latter the ribs are attached. The caudal or tail vertebræ have an inferior or hæmal arch, but no distinct transverse processes. The ribs are not attached below to a sternum or breastbone, but simply imbedded in the muscles. The *interspinous bones* of F. are dagger-shaped bones which exist in the middle line of the body, and are attached below to the spines of the vertebræ; above they support the rays of the dorsal and anal fins. The *fins* of F. may be divided into two groups. The *pectoral* and *ventral* fins are paired, and represent the fore and hind limbs of other vertebrates respectively. The other fins are single or median, and are placed in the middle line of the body. Those on the back are the *dorsal* fins; the *anal* fin is placed near the *anus* or *vent* in the lower aspect of the body, and the *caudal* or *tail-fin* is the chief agent in locomotion. The fins are supported by bony rays or spines, and by soft rays. The *caudal* fin of F. is always set vertically, and works from side to side, the tail-fin of the whales and Sirenia amongst mammals being placed horizontally. The *digestive system* of F. comprehends a mouth, usually provided with numerous teeth, which are replaced when lost or injured, and which are not set in sockets, but attached by a ligament to the bones of the mouth. The stomach (*h*) is large, and provided at its hinder extremity with a number of blind sacs or appendages, varying from one to sixty or more in number, named *pyloric cœca,* which are supposed to represent a *pancreas* or sweetbread. The intestine (*e e*) is shut as a rule, and is often provided with a spiral coil, serving to increase its digestive area. The liver (*d*) is usually large and oily. The *kidneys* (*k*) are also large, and a true urinary bladder is doubtfully represented. The blood of F. is cold, and contains nucleated blood corpuscles. It is of red colour in all save the lancelet. The heart (*a*) is two-chambered, and consists of an *auricle,* which receives the venous blood from the body, and of a *ventricle* which propels it to the *gills* or *branchiæ* (*q*) for purification. In many F. a third chamber of the heart is formed by the dilatation of the great blood-vessels of the gills, this dilatation being named the *bulbus arteriosus.* In some F. (*e.g.,* sharks, &c.) this latter structure contracts in a rhythmical manner. The *gills* (*q q*) or breathing organs of F. consist of comb-like structures borne on branchial or gill arches, and composed of delicate filaments in which the blood is exposed to the aerating influences of the external water. In the sharks, rays, &c., the gills exist in the form of pouch-like cavities. The water for aeration is admitted by the mouth, and after passing over the gills and yielding up its oxygen, is ejected from the gill-chambers at the sides of the mouth, behind the *operculum* or gill-cover (*p*), or in the sharks, &c., by special apertures. The *air* or *swimming bladder* of F. (see AIR-BLADDER), or *sound,* as it is also called, is used for altering the specific gravity of these animals, and thus enabling them to rise or sink in the water. The *nervous system,*

Anatomy of Fish.

comprising a brain, spinal cord, and nerves, is distinct in all F. save the Lancelet (q. v.). The senses comprise large eyes, internal *ears,* touch (performed by the lateral line), and smell. The nostrils of all F., except the hag-F. (*Myxine*) and the *Lepidosirens* or mud-F., are simple closed or pocket-like sacs. F. are *oviparous* animals, producing eggs, from waries (*i i*), the young being afterwards hatched. But in some cases (skate, dog-F., &c.) the eggs may be enclosed in special cases or capsules, and in sharks there would appear to be an intimate connection between the parent and young, reminding one of the *placental* connection of *Mammalia.* As in all *Vertebrata,* the sexes are distinct. The *habits* of F. differ very widely. Migration is not uncommon with many, although the nature of the migratory movements is less susceptible of determination than in the case of land animals. An idea of the *classification of F.,* according to modern zoology, may be formed from the following table:—

Order.	Example.
1. *Pharyngobranchii* (pharynx-breathers).	The amphioxus or lancelet.
2. *Marsipobranchii* (pouch-gilled breathers).	Lampreys and hag-F.
3. *Teleostei* (F. with bony skeletons).	Cod, salmon, herrings, and all familiar F.
4. *Elasmobranchii* (plate-gilled breathers).	Sharks, rays, dog-F., &c.
5. *Ganoidei* (F. with ganoid scales)	Sturgeon, bony pike, &c., and many fossil F.
6. *Dipnoi* (F. breathing by gills and rudimentary lungs).	Lepidosirens or mud-F.

(By the majority of naturalists the *Dipnoi* are classified as a subdivision of the *Ganoidei,* this arrangement reducing the orders of F. to five in number.)

Fossil F.—The first traces of F. which appear in the rock formations occur in the Upper Silurian formations, these traces, consisting of the fin-spines and placoid scales, belonging to F. most nearly allied to the *Elasmobranchii.* In the Devonian or Old Red Sandstone rocks, fish remains are so plentiful that this epoch has been named the 'Age of F.' The Devonian fossil F. belong chiefly to the Ganoid order. The Teleostean or true bony F. do not make their appearance until the Cretaceous epoch at the close of the Mesozoic period; and three groups of F. (*Marsipobranchii, Pharnygobranchii,* and *Dipnoi*) have, as far as is yet known, left no traces of their existence in any rock formation.

Law Regarding F.—They become the property of him who catches them except royal fish. (See FISHES, ROYAL.) Though it requires a royal grant to entitle a man to fish for salmon, yet the salmon when taken by a man who has no grant belong to himself. 24 and 25 Vict. c. 96 imposes penalties on persons taking fish without permission from water which is private property. Persons found angling against the provisions of the Act, which does not extend to Scotland, may be required by the owner or his servant to deliver their fishing implements. On refusal they may be forcibly seized. But if the implements are taken, there is no further penalty or damage. To destroy the dam of any fishpond which is private property, with intent to destroy the fish, or to put lime or other noxious material into it with the same intent, renders the offender liable to penal servitude.

Fishes, Royal, are those which by common law belong to the crown, being the whale or the sturgeon when thrown ashore or caught near the coast. The law is a little obscure, however, and is modified or altered by local custom.

Fish-Hooks are made by a series of hand processes. The steel wire is first cut into lengths, and then slit with a lever knife near one end to form the barb. Each length, after being filed round the point and barb, is bent to the hook form by means of an instrument with a suitable core and pin. The end of the shank is then hammered flat to enable the hook to be secured to the line. The hook is next hardened, made stiff and elastic by tempering, and finished by blueing. F.-H. are sometimes swivelled at the head to prevent the twisting of the line. Redditch, in Worcestershire, is the great place for the manufacture of F.-H. In the United States they are made extensively by Crosby's automatic machine, which, it is said, is capable of turning out 6000 highly-finished F.-H. every hour.

Fish'ing-Tac'kle. See ANGLING.

Fish-Lice, or **Sea-Lice**, a name given to several genera and species of lower Crustaceans, from their parasitic habits. They attach themselves to the skin, gills, and other parts of fishes and other aquatic animals. One of the best-known forms is *Cymothöe œstrum*, which adheres to fishes by means of its hooked legs and suctorial mouth. Other genera are *Achtheres*, of which *A. percarum* of the perch is a good example; *Argulus*, of which *A. foliaceus*, common on fresh-water fishes, is a familiar species; and *Caligulus*, species of which are common on marine fishes. These fish-lice belong to the Crustacean orders *Rhizocephala* and *Ichthyophthira*. In their development they pass through a metamorphosis, appearing at first as lively free-swimming bodies, but eventually losing their limbs, &c., settle down to a parasitic life.

Fish'ponds. See PISCICULTURE.

Fish-Skin Disease, or **Ichthyo'sis Ve'ra**, is a disease of the epidermis characterised by a general dryness and roughness of the skin, modified in appearance in different regions of the body. The defective nutrition of the texture of the skin is most apparent in the limbs, particularly the arms, and there is a marked deficiency of subcutaneous adipose tissue. When the skin is hard, it may be moved about on the subcutaneous fascia as if there were no binding tissue between the under surface of the corium and the structures beneath; and it remains stiff like leather, apparently depending upon the lines of motion for its power of adaptation to the movements of the joints. The skin of the face may be perfectly normal, while that of the hands and arms may be dry and wrinkled, like the withered limbs of old age. Treatment:—General hygenic measures, nutritive diet with cod-liver oil; arseniate of soda, or Fowler's solution; Donovan's solution: locally, frictions and inunctions, bathing, &c. The disease is of a very obstinate nature, and its cure is difficult and seldom complete. See *Diseases of the Skin*, by Erasmus Wilson (Lond. 1857), T. Macall Anderson (Lond. 1874), and by Tilbury Fox (Lond. 1876).

Fissip'arous, a term used to describe reproduction by a process of division. It is well seen in the reproduction of many of the lower forms of animal and plant life, and it also probably takes place in the human body in the formation of colourless blood cells, pus corpuscles, modified epidermic cells, &c.

Fissiros'tres (Lat. 'split-beaked'), a sub-order of the order *Insessores* (q.v.) or Perching birds, distinguished by the so-called 'cleft' nature of the beak; the 'gape' or mouth-opening being very wide, prolonged far back on the head, and pointed with bristles, of service to these birds in the capture of insect prey. The beak itself is short. Typical examples are the swallows, &c. (*Hirundinidæ*), the swifts (*Cypselidæ*), and goat-suckers (*Caprimulgidæ*)

Fissurell'idæ, a family of Gasteropodous Molluscs including the forms popularly known as 'keyhole limpets.' The shells of these forms have an opening at the apex, which has suggested the popular name. The family belongs to the Holostomatous group of the Prosobranchiate Gasteropods. The shell is conical, and its aperture is subservient to the respiration or breathing of these forms. *Fissurella maxima* is a familiar species, and the family also includes the genera *Emarginula* and *Parmophorus*.

Fis'tula (Lat. 'a pipe'), or **Sin'us** (Lat. 'a winding'), a narrow passage, the walls of which are always indurated, consisting of a layer of imperfectly-formed granulations discharging ichorous pus. The passage, which is often long and winding, has an external orifice somewhat protuberant, situated under or in the midst of granulations. F. is, therefore, a chronic abscess without disposition to close. The causes of this non-closure may be—(1) the presence of some foreign body, such as a piece of dead bone; (2) the passage of irritating secretions, such as urine, fæces, saliva, &c.; and (3) the contraction of neighbouring muscles preventing the coalescence of the sides of the abscess, as when the abscess is situated in the neighbourhood of the sphincter ani. The treatment of F. must have reference to its cause, and the foreign body or irritating substance must be removed. In recent cases a cure may be effected by pressure; or a healthy inflammation may be excited by injecting the F. with tincture of iodine; by means of a seton; by actual cautery, or by galvanic cautery. The treatment of F. should always be intrusted to a skilful surgeon, and in such a case a complete cure may be effected in even the most distressing cases. That form of the disease called vesico-vaginal F., which renders life a burden to those who suffer from it, may now be cured by a simple and almost painless operation, for which the profession is indebted to the ingenuity of American surgeons, and especially to Dr. Marion Sims of New York.

Fistular'idæ, a group of Teleostean fishes, which from the prolongation of the jaws have been named 'pipe fishes,' 'tobacco-pipe fishes,' 'bellows fishes,' and the like. The genera *Centriscus*, *Fistularia*, are illustrative of this group, which is distinguished by the elongated body, by the tube-like jaws and small mouth, by the scaly body, and by the ventral fins being placed on the abdomen and possessing six spines. The true pipe-fishes or *Syngnathidæ* belong to a different group, that of the *Lophobranchii*.

Fistuli'na, a genus of fungi related to Boletus (q. v.), and represented by the British species *F. hepatica*, found growing on oaks, beeches, chestnuts, and walnut trees. The specific name *hepatica* is derived from the appearance of these fungi when old; the surface becoming brown, and not unlike the liver in outward aspect. The colour is red, and the fungus may attain a size of 5 feet in circumference, and a weight of 7 or 8 lbs. Berkeley gives an instance of one which weighed 30 lbs. The F. is an esculent, and is eaten on the Continent.

Fitch'y, or **Fitché**, in heraldry, pointed at the end; *e.g.*, *a cross fitchée* is a cross with one end sharply pointed.

Fits, a term popularly applied to any sudden seizure of disease, more particularly to those implying loss of consciousness or a change in the condition of the mind, such as apoplexy, convulsions, epilepsy, &c.

Fitz (Fr. *fils*, Old Fr. *fiz*, from Lat. *filius*, 'a son'), a prefix denoting at first merely descent, and afterwards applied to illegitimate sons of kings and princes of the blood—as *Fitzroy*, 'son of the king.'

Fitz'roy, a name of frequent occurrence in Australian topography, and derived from Sir Charles A. Fitzroy, who was governor of New South Wales from 1846 to 1855, and under whom the colony received the boon of responsible government. After him are named the following:—1. A town in Victoria, forming a suburb of Melbourne, but under distinct municipal government, and inhabited chiefly by the more well-to-do citizens. Pop. 16,500.—2. A county of New South Wales in the Clarence (N.E.) district.—3. A river in Queensland, which rises in the Peak Range, and after a tortuous course of 300 miles, falls into the S. Pacific at Port Curtis, in 23° 30′ S. lat., 151° 50′ E. long. The important town of Rockhampton (q. v.) is situated on the F., 35 miles from its mouth.

Fi'ume ('the river,' formerly *St. Veit am Flaum*, from the Lat. *Fanum St. Viti ad flumen*: Illyrian *Reka*), a town of Austro-Hungary, in the district of F., 40 miles S.E. of Trieste. It stands on the Adriatic, in a narrow and wild pass, where the Fiumara falls into the Adriatic. Rocky heights, on one of which is the old castle of Fersata, rise behind it, and before it the Bay of Quarnero is studded with green islands. The old town, straggling and gloomy, overhangs the new town, which has many handsome, spacious, and colonnaded streets. Among the finest buildings are the cathedral of St. Veit, the nunnery, gymnasium, and hospital. Near F. is a church much frequented by pilgrims. F. has manufactures of linen, wool, leather, paper, &c., and considerable shipbuilding. It was once the chief port of Hungary, but its trade has fallen greatly away. Pop. 13,314; of the district, 17,884.

Five Forks, a district in Dinwiddie county, Virginia, where the Federals, under General Sheridan, won a decisive victory over the Confederates, April 1, 1865.

Five Points is a name given to the five articles of doctrine which the Arminians presented to the States of Holland (1611), as embodying their views on predestination and grace, on which alone at that time they differed from Calvinists. See ARMINIUS.

Fives, a game played by striking a ball with the hand against a high wall, so named because the number of points, fifteen or twenty-five, necessary to score a win is a multiple of five. The 'bounds' of the game are marked by one chalk line on the wall, a yard from the ground, and a second on the ground, 10 feet from the wall. The players of each side engage the ball alternately, striking it either as it rebounds from the wall, or as it springs up from the ground. Missing the ball or striking it so that it falls within the 'bounds' counts one point for the opposing side. F. is an ancient game, and in England was formerly called 'hand tennis.' In 'bat-F.' the ball is struck with a bat in place of with the hand.

Fixed Air was the name given by Black, its discoverer, to carbonic acid gas. He so named it in consequence of the power possessed by certain substances (potash, lime, magnesia, &c.) of absorbing or *fixing* it.

Fixed Bodies are those which cannot be volatilised, nor which suffer change when they are exposed to a high temperature.

Fixed Oils are such as do not evaporate at ordinary temperatures; for example, the oils of olive, linseed, and rapeseed.

Fixed Stars. See STARS.

Fix'ing, the term applied in photography to the operation following development, and immediately preceding the exposure of the picture to diffused light. It consists in depriving the picture of the salts surrounding the image, which are still sensitive to light, by means of hyposulphite of soda or cyanide of potassium solution.

Fix'tures. Whatever is fixed to the soil or outhouse or farmyard wall so as to become a part of it, will at the expiration of a lease belong to the lessor, but a tenant may remove anything which he has placed for the convenience of his trade, such as engines, counters, &c., provided he does it during his term, and has not made an agreement to the contrary. Erections for the purpose of farming and agriculture do not come under the exceptions with respect to trade, and cannot be taken down again, but a nurseryman in England is allowed to remove his greenhouses and also his small trees and shrubs (Wyndham *v.* Way). Though on this special point a contrary decision has been come to in Scotland, the same considerations of public expediency will generally determine the law regarding F. in both countries. The general rule is, that things fixed with nails cannot be removed, but if fastened by a screw they may, provided the removal does not cause serious damage to the premises. All F. put in by the tenant must be removed during his term, otherwise on expiration of the term they become the landlord's. Mr. Commissioner Fonblanque lately came to the following conclusions in the case of a bankrupt:—That articles merely resting on the soil, however heavy, are goods and chattels (see CHATTELS); that if they are slightly connected with one another and with the freehold, but may be severed without material injury to the freehold, they are goods and chattels, as are also articles fixed to the freehold by bolts or screws; but that articles mainly sunk in the soil or built on it are real estate. In Dumergin *v.* Rumsey, it was held that tenant's F. are not chattels till severed, and it is competent to a landlord to make an agreement with his tenant which shall, notwithstanding an abandonment by the tenant of his property in the F. during the term, in the event of an execution against the tenant, enable the landlord to re-enter and retain the F. against the executing creditor. See FENCES.

Flacc'us, C. Valerius, a native of Padua, who is supposed to have died about 88 A.D., is now known only as the author of an unfinished epic poem in eight books on the Argonautic expedition. 'F. has attained to somewhat of the outward form, but to nothing of the inward spirit, of his great model the Æneid.' The *Argonautica* was translated into English verse by Nicholas Whyte (1565).

Flag (lit. 'that which flies or flutters,' from Old Eng. *fleogan*, 'to fly'), a light cloth worked in a specific shape or pattern, and displayed in the field or on board ship as an emblem or signal. Under this designation are included the royal standard, the colours of regiments, and all ensigns, banners, and the signals used in the army for marking off ground to be occupied by troops, and in the navy for the transmission of messages from ship to ship. The great flag of Britain is the royal standard, bearing the arms of the United Kingdom, and hoisted only in the presence of the sovereign or a member of the royal family; the next is that of the Lord High Admiral—an anchor on a red field; and the third in importance is the Union Jack (q. v.), the national flag of Great Britain. The British ensign is a red F. with the Union Jack borne as a *canton*, or occupying the upper corner next the flagstaff. In the British navy the centre squadron, commanded by the admiral, carry red ensigns at the *main;* the van-squadron, commanded by the vice-admiral, carry white ensigns at the *fore;* and the rear squadron, commanded by the rear-admiral, carry blue ensigns at the *mizen* or sternmost mast. The broad pennant is the special flag of an admiral, but every man-of-war carries a pennant, the colour of which defines the squadron to which the ship belongs. By means of flags of easily-distinguished shape and colour, each of them representing letters or numbers signifying words or sentences, and to which there is an official key, vessels can communicate with freedom, certainty, and rapidity. Nelson's famous message at Trafalgar was communicated by means of F. signals, and so rapidly, that, in recognition of it, all the ships of the fleet were manned simultaneously. In 1855 a new system of signalling for the merchant service was adopted by a specially-appointed committee, by means of which, using eighteen flags and three pennants, 78,642 signals can be made, each consisting of not more than four flags at a hoist.

Flag-Captain, the captain who sails in the flag-ship—*i.e.*, the admiral's ship in any squadron—and who relieves the admiral of many of the ordinary duties of command.

Fla'gellants (Lat. *flagellantes*, 'the scourgers'), the name given to those mediæval fanatics who believed in the possibility of expiating sin by self-inflicted castigation. This practice was not a very early one in the Christian Church, flagellation being used at first solely as a punishment. About the 11th c., however, it began to be employed as a substitute for pecuniary penance, a year of penance being commuted into the payment of 26 silver *solidi* (£4) or the infliction of 3000 lashes. It is told of one famous hermit, St. Dominic of the Iron Cuirass, that he inflicted on himself in six days so many stripes that he discharged a century of penance (Fleury's *Eccles. Hist.*, vol. xiii.). Numerous penitents of both sexes adopted this mode of self-torment, and it is said to have been a special favourite among ladies of quality (Chais's *Lettres sur les Indulgences*, vol. ii.). The practice continued down to the end of the 13th c. as one of the ordinary forms of penitential observance, but at that period there broke out in Italy an endemic of superstition, due to a belief in the approaching end of the world, which took the shape of flagellantism, and rapidly spread all over Europe. The F. became a regular society; they marched with naked shoulders through the streets of the towns, each one holding a scourge of leathern thongs, with which he lashed his back till the blood ran. Men, women, and even children of tender years joined in these processions, and all classes were represented. Sometimes the throng was led by a priest; banners, crucifixes, and at night lighted tapers, were borne before them. At times they would stretch themselves on the earth in the form of a cross, and in this attitude undergo the severest discipline at each other's hands. The chief 13th c. outbreak of this fanaticism began at Perugia in 1260, and though promptly suppressed in Italy, showed itself in various districts of France and Austria. The F. next became prominent in the middle of the 14th c., when the dreaded plague called the Black Death evoked a universal religious frenzy. This outbreak was both wider spread and more extravagant than the former. It reached as far as England, appearing in London. A band numbering 120 exhibited their self-imposed tortures in the streets of the city, but do not appear to have succeeded in making any converts (Lingard's *Hist. of Eng.*, vol. iii.). The Church, however, was at this period forced to interfere, flagellantism having been elevated by its votaries into the position of a sacrament, as a 'baptism of blood.' Clement VII. anathematised the F.; but they were not suppressed until their frequently impure excesses had overrun Germany, the Low Countries, Sweden, and Switzerland (Baluze's *Vitæ Pontif. Avenion.*, vol. i.). The third and final outbreak of the mania took place in 1414 in Thuringia and Lower

Saxony. Flagellantism here assumed its wildest phase, and became distinctly heretical, rejecting all practical religion, the sacraments, purgatory, prayer for the dead, &c. Salvation was to be secured by the scourge, and that alone. The leader of these fanatics was one Konrad Schmidt of Sangerhausen, who was burned in 1414 by Schönefeld the Inquisitor, along with many of his followers. Schmidt's 'Fifty Articles of the F.' were condemned by the Council of Constance (Von der Hardt's *Acta Concilii Constant.*, vol. i.), and the heresy was thus stamped out. Flagellantism, as an excess of religious revival, did not again appear; but the Romish Church to this day sanctions a discipline of self-castigation. See Schötgen's *Historia Flagellantium*, Boileau's *Histoire des Flagellans*, Delolme's *History of the F., or the Advantages of Discipline* (an English paraphrase of Boileau's work), Muratori's *Antiq. Ital. Medii Ævi* (vol. vii.), Baluze's *Miscellanea* (vol. i.), Forstemann's *Christliche Geisslergesellschaften*, Gerson's tract *Contra Sectam Flagellantium*, Wadding's *Annales Minorum Fratrum*, Mosheim's *Church History*, Hallam's *Middle Ages*, *Mysticism and the Mystics*, and Cooper's *Flagellation and the F.*

Flage'olet, an instrument with a mouthpiece like a whistle, and fingered like a flute. It is easy to play, and the quality of its tones is pleasant, but it does not possess sufficient individuality or richness to give it a place among orchestral instruments. The Harmonics (q. v.) of the violin and other stringed instruments have sometimes been called, very clumsily, F. tones.

Flag'-Lieutenant, the officer in a flag-ship who communicates the admiral's orders, either personally or by signal, to the ships in command, and performs generally such duties as an aide-de-camp is intrusted with in relation to a general.

Flag'-Officer, in the navy, is one who has the right to carry a flag at his mast-head denoting his rank—a privilege confined to admirals, vice-admirals, rear-admirals, and commodores, or captains in command.

Flag of the Prophet, the sacred flag (*Sanjak-Sherif*) of the Moslem, and the most highly-prized of the Mohammedan relics, is a black banner formed of the curtain that hung in front of the door of Ayesha, one of Mohammed's wives; was obtained by the followers of Omar at Damascus; and is preserved in a casket in the Seraglio, where it is guarded by emirs. It is never unfurled.

Flag'-Ship, the ship in which the admiral sails, and which carries his flag. From this ship, usually the largest in the squadron, orders are signalled to the other vessels.

Flag'stones are rocks of calcareous or argillaceous sandstones and limestones, which split easily into large flat slabs useful for paving. Those of Yorkshire and Caithness are well known for their hardness and durability.

Flahault de la Billarderie, Auguste Charles Joseph, Comte de, a French soldier and diplomatist, was born at Paris, April 20, 1785, became aide-de-camp to Napoleon, distinguished himself in the Peninsular war and at Leipsic, was made a general and count, and fought at Waterloo. He afterwards married a Scottish heiress, Lady Keith, and in 1830 recovered his position in the French army. He was ambassador at Vienna from 1841 to 1848, and at London in 1860. He was made Grand Chancellor of the Legion of Honour in 1864, and died at Paris, 2d September 1870.

Flam'borough Head (Old Eng. *Fleamburh*, so named probably from its *flame* or beacon), a headland on the Yorkshire coast, on the N.E. boundary of Bridlington Bay. It is formed by a line of chalk cliffs, rising to 450 feet, and runs for 6 miles into the sea. It has a lighthouse 214 feet high, and is crossed by an old British work known as Danes' Dyke.

Flamboy'ant, the latest and feeblest style of Gothic architecture in France. It is named from the flame-like forms of its characteristic traceries—intricate reticulations of delicate gauzy texture, woven of thin, wavy lines into meshes of every diversity of size. There is good and bad F., the latter being that in which ornament is allowed to impair construction. Even good F. is Gothic without magnificence or serenity, and its restless caprice is only redeemed by endless variety and floral grace. Ruskin says, 'The F. leaf-mouldings are beautiful, because they nestle and run up the hollows, and fill the angles, and clasp the shafts' in the manner of natural leaves. A feature of the style is the twining of twigs and stalks into pillars. When mouldings meet, they are apparently interlaced or run through each other. While the windows and doors are generally large and richly carved, the wall surfaces are comparatively bare. A mark of the most debased F. is the figure of the *fleur-de-lis* in tracery bars. F., which prevailed in the 15th and 16th centuries, is well represented in the cathedral of Chartres, the pediment of the west front of Rouen, the lantern of St. Ouen (Rouen), the central tower of Bayeux, and the buttresses of St. Gervais at Falaise.

Flame (Lat. *flamma*) is the luminous appearance accompanying the gradual combustion of inflammable substances in the air. Combustion is really an evolution of heat produced by a transformation of the energy of chemical affinity existing between the combustible and oxygen; and if the heat produced be sufficiently intense, part of it will take the higher form of light. The luminosity of a F. is generally supposed to depend upon the presence of solid particles, probably carbon, which glow under the action of the intense heat; and this theory is supported by the continuous spectrum which luminous flames give. In the common gas F. the presence of such particles is little doubtful. This is readily shown by the deposition of soot upon a cold body held in the F. It is now known, however, that gases under pressure give out a continuous spectrum; and experiments of Dr. Frankland indicate that luminosity does not necessarily depend upon the presence of solid particles. Much of the luminosity of our ordinary flames is due to imperfect combustion; and if by any means a gas jet is diminished in light-giving power, it is increased in its heating capacity. This is well exemplified by Bunsen's burner—a simple contrivance of incalculable value in the laboratory. Its construction is such that the stream of gas issuing from the jet is first made to traverse a tube of comparatively wide bore, which is perforated at its lower extremity with holes for the admission of air. The gas is thus thoroughly mixed with air before it is lighted, and a continuous draught is produced, so that the combustion is rendered perfect. The Bunsen F. is of a transparent blue colour, and in its interior is a hollow cone containing a mixture of air and gas which is not sufficiently raised in temperature to permit of combustion. The hottest part of the F. is just above this cool cone. For combustion a certain temperature is necessary—the principle upon which Davy constructed his Safety-Lamp (q. v.), whose wire-gauze covering reduces the outside atmosphere to a temperature too low for the combustion.

Flam'en, a Roman priest, so named from the band (*filum*, *filamen*, *flamen*) of white wool which he wore round his head. These priests were fifteen in number, and their services were appropriated to a particular deity, from whom they derived a special name. The three principal flamens, known as the *Majores*, were the *F. Dialis*, *F. Martialis*, and *F. Quirinalis*—the priests respectively of Jupiter, Mars, and Quirinus—and were chosen always from the patricians, while the others—the *Minores*—might be plebeians. The special dress of the F. was the apex (a cap), the læna (a cloak), and a wreath of laurel. The *F. Dialis* was the most distinguished of the flamens, and enjoyed many privileges; as, for example, he had a right to a lictor, to the curule chair, and to a seat in the senate. His wife was called *Flaminica*, and on her death the *F. Dialis* was bound to resign.

Flamin'go (*Phœnicopterus*), a genus of birds usually included in the order *Grallatores* or Waders, to which it is allied by length of limb; but many ornithologists regard it as more appropriately ranked with Natatorial or Swimming birds, from the webbed feet. The three front toes are fully united by a web, and the bill is broad and lamellate, resembling that of the Lamellirostral *Natatores*. The bill is also of singular form, being bent abruptly downwards from the middle. The toes themselves are short, and the nostrils are placed in a groove and covered with membrane. The first and second quills are the longest of the wings. The tail is short. The typical example of the F. is the *Phœnicopterus ruber*, or common F. of S. Europe and other parts of the Old World. It inhabits the sea-coasts and marshes, and is gregarious in its habits. A sentinel bird watches over the safety of the flock. When at rest, the F. lies on the ground with its legs doubled under it, and its neck curiously bent. The nest is made of mud and

earth so as to form a small hillock. The eggs are white, and number two or three. The colour is scarlet when in full plumage, the quill feathers being jetty black. The bill is orange-coloured at its base and black at the top. The average height of a full-grown F. is 6 feet. The common American species has received the name of *P. Americanus.*

Flamingo.

Flamin'ia Via, the famous highway leading N. from Rome, issued from the city by the Flaminian Gate at the northern angle of the Capitoline Hill. It proceeded to Narnia, in Umbria, and thence by Fulginia to Fanum Fortunæ on the Adriatic, from which it passed on to Ariminum, beyond which it extended under the name of the Æmilian Way through Cis-Alpine Gaul. One loop-line left the main road at Narnia, and passing through Interamna and Spoletium, rejoined it at Fulginia. Another, striking off at Nuceria, diverged to Ancona, and united with the main road at Fanum Fortunæ.

Flamini'nus, T. Quintius, the most distinguished representative of a family of the Quintian gens, was born about B.C. 230. He was elected consul B.C. 198, and obtained Macedonia as his province. He threw himself with great ardour into the war with Philip, and in the course of the struggle both achieved military successes and displayed great diplomatic skill. After the complete defeat of the Macedonians at Cynoscephalæ, B.C. 197, terms of peace were concluded, by which Philip relinquished all his Greek possessions in Europe and Asia; and during the Isthmian games of B.C. 196, F. proclaimed the freedom of Greece. He took leave of the Greeks B.C. 194, and on his return to Rome celebrated a splendid triumph of three days' duration. Peace was soon disturbed by the war in which the treacherous Nabis, tyrant of Sparta, was subdued. The most notable event in the subsequent career of F. was his connection with the death of Hannibal, who took poison, fearing lest he should be delivered up to the Romans by Prusias of Bithynia. F. died B.C. 174.

Flamin'ius, Caius, was tribune of the Roman people B.C. 230, and carried by popular support an agrarian law for the distribution of the recently-conquered territory of the Cis-Alpine Gauls. When consul (223), F. gained a great victory over the Insubians. His censorship (220) was distinguished by the two great works that bear his name, the *Circus F.* and the *Via Flaminia*. He was elected consul for a second time (217), and immediately marched against Hannibal, who was advancing southwards. F., with the greater part of his army, perished in the battle on the shores of Lake Trasimenus, B.C. 217.

Flam'steed, John, the first astronomer-royal of England, was born at Denby, near Derby, August 19, 1646, and at an early period showed so remarkable a power in the calculation of eclipses of the moon, that through Sir Jonas Moore, then Surveyor-General, he was appointed astronomer to the king in 1675. The same year he took holy orders, and nine years later was presented to the living of Burslow, in Surrey. Scientifically he is chiefly remarkable as the earliest of practical astronomers. He made the first valuable catalogue of the fixed stars, and was the first to introduce the method of simultaneously observing the right ascension of the sun and stars. F. died 31st December 1719. The partial publication of his leading work, *Historia Cœlestis Brittanica*, by Halley, against his wish, led (as was ascertained from the publication of some of his papers in 1835) to a quarrel between F. and Halley, in which Sir Isaac Newton was involved. This work, which was begun to be printed along with an *Atlas Cœlestis* in 1719, was not published till 1725. See Baily's *Account of F.* (Lond. 1835, Supp. 1837).

Flanch, The, in heraldry, is a segment of a circle drawn on each side of the shield, and is said to have had its origin in the dress of the 14th c. Guillin says that flanches are 'a proper reward for the services of a gentlewoman to her sovereign.'

Flan'ders (Flĕm. *Vlaendern*) is the name of a territory in the basins of the Scheldt and Lys which has often varied in extent, and which was formerly a powerful sovereign county. The ancient occupants of this country, whom Cæsar subdued, were the Celtic Morini, and various savage German tribes, as the Nervii and Menapii. The name F. was derived from the *Vlandergau* (*pagus Flandrensis*), but this was merely the district surrounding Sluis and Bruges. In the time of Karl the Great, F., then a region of wild morass and dense vegetation, was placed under a race of bold 'foresters,' who easily wrested the territory from his feeble descendants. By the Treaty of Verdun (843) F. and Artois were acquired by the Karolings of the newly-formed western Frankish kingdom. On the irruption of the Northmen the vassal rulers of the country were made wardens of the Frankish north-eastern coasts. In 864, Judith, daughter of Karl the Bald, and widow of Æthelwulf of England, was married to Baldwin (q. v.), surnamed *Bras-de-Fer*, who subsequently was created 'Count' of F., and who laid the foundation of the industrial greatness of his 'mark' or county. Among his more prominent successors was Baldwin IV., the Bearded (988–1036), who became a prince of the empire by receiving in fief from Heinrich II. the burgrafdom of Ghent, Walcheren, and the Seeland Islands. The son of Baldwin IV., the Pious, Baldwin V., gained a part of Lower Lothringen, between the Scheldt and Dender (the *Alosterland*), the episcopal supremacy of Cambray, and the county of Hainault (Hennegau), founding the Flemish-Hainault line in 1070. Of this line, the Flemish section died out with Baldwin VII. in 1120, whereupon some six claimants strove to gain the succession, which was finally secured by Dietrich of Elsass in 1128. Grown by this time into a flourishing state, F. had given crusading dynasties to Jerusalem and to the Latin empire of Constantinople. The Flemish weavers, rapidly becoming wealthy merchants, were beginning to receive a share of the political recognition foreshadowed by the first civic charter or *keur* granted to Middelburg in 1217. During the French and English wars of the 13th c., F. aided the latter power, although nominally a vassal of the former. In 1280 Margarethe II. died, leaving two sons by different marriages, John of Avennes and Guy Dampierre, who succeeded to Hainault and F. respectively. The revolt of Guy against Philippe le Bel (1297) led to the conquest of F. and its annexation to France; but the Flemings achieved their independence by the famous 'battle of spurs' at Courtrai in 1302. Under the oppressive rule of Count Louis I. of Dampierre, grandson of Guy, occurred the turbulent popular outbursts headed by the Arteveldes (q. v.). By the marriage of Philip I. of Burgundy the family of Valois-Burgundy replaced that of Dampierre in 1369, and F. was brought within the circle of the German empire. (See BURGUNDY.) Meanwhile F., along with Holland, was fast attaining its highest reach of material splendour; and its rich populous cities, Ghent, Bruges, Ypres, &c., were ready to resist any encroachment on their 'liberties.' After the death of Charles the Bold (1477), and the consequent disruption of the Burgundian possessions, F. went to his daughter Marie, who married Maximilian of Austria. The Treaty of Madrid (1526) formally abolished the vassalage of F. to France. On the abdication of Charles V. in 1556, F. came to the Spanish line of the House of Hapsburg with Philip II., but the territory was subsequently much diminished by the Peace of Westphalia (1648), which transferred a portion in the N. to the States-General, and by the conquests of Louis XIV. secured to France by the treaties of Aix-la-Chapelle, Nymwegen, and Utrecht. By the Congress of Rastadt (1714) the remainder of F. came again to the House of Hapsburg; but it was conquered by the French in 1794, and remained an integral part of the republic and empire till the Congress of Vienna (1814) conferred it on the kingdom of the Netherlands. It now forms the two Belgian provinces, East and West F. (q. v.). See Van Praet, *Histoire des Comtes des Flandres* (Bruss. 1828); Kervyn van Lettenhoven,

Histoire des Flandres (6 vols. Bruss. 1847–51); Le Glay, *Des Comtes de Flandres jusqu'à l'Avènement des Ducs de Bourgogne* (2 vols. Par. 1843); and Paul Fréderica, *Essai sur le Role Politique et Sociale des Ducs de Bourgogne dans le Pays-Bas* (Ghent, 1875).

Flanders, East (*Oost Vlanderen*), a province in the N.W. of Belgium, with an area of 1160 sq. miles, and a pop. (1873) of 854,366. It has a flat surface, and is watered by the Scheldt, and its tributaries the Dender and Lys. The sandy soil, which has undergone spade-culture, is very rich, yielding various grains, flax, hops, hemp, &c. Fine flax is produced in the *Land van Waes*, a region between Antwerp and Ghent, formerly a barren heath. E. F. is portioned into a great number of small farms, and is one of the most populous parts of Europe. There are large linen, cotton, woollen, lace, and silk industries, besides some 435 breweries and 170 distilleries. Ghent is the capital, and among the other towns are Alost, St. Renaix, Lokeren, and Eecloo.—**West F.**, the most westerly province of Belgium, is bounded N. by the North Sea, and W. and S. by France. Area, 1250 sq. miles; pop. (1873) 682,921. It is watered by the Lys and Iser, and is level and cultivated, except along the coast and in the N., where there are broad, low sand-dunes, in part covered with pine-trees. The chief towns are Bruges, Ostend, Courtrai, and Ypres.

Flange, in construction, a projecting rim placed round the edge of various parts of machines or apparatus. It serves commonly to afford the means of connecting (by bolts) the piece to which it belongs with other parts of the machine, but in some cases it has an entirely different purpose, as in the flanges of railway carriage wheels.

Flank (*i.e.*, 'the side') in a military sense means the extreme right and left of an army or encampment. To *flank* is to take up such a position as will strengthen the main body of an army or brigade, and at the same time have the men who perform the evolution well out of range of the enemy's fire. To *outflank* is to increase one's front so that by extending the line a general will be in a position to threaten or command the flanks of the opposing but less widely-extended line. *F. companies* is the name applied to the grenadiers and light infantry companies of regiments, as these generally occupy the right and left extremities when a battalion is in line. *Flanking parties* are bodies of cavalry and infantry employed to harass the flanks of an enemy. *Flanks of a frontier* are sorts at the extremities of a frontier line, within which an attacking force will be careful not to enter, lest his retreat be cut off. For F. in fortification see FORTIFICATION.

Flann'el (Welsh *gwlanen*, Fr. *flanelle*), a woven woollen fabric of a loose texture, much used for underclothing, shirting, &c., on account of its softness and warmth. Wales still sustains the reputation it early earned for the excellence of its hand-made F. Many varieties of the fabric are produced at Rochdale, Halifax, Leeds, Bury, and Salisbury.

Flat, in music (denoted thus, ♭), a sign indicating the substitution of a note a semitone lower for the note on the staff before which it is placed. See NOTATION.

Flat-Fish, the common name for the flounder, plaice, sole, turbot, brill, halibut, and other Teleostean fishes belonging to the family *Pleuronectidæ* of the section *Anacanthini*. They can only be called *flat* in the sense that their *sides* are flattened to a much greater extent than is common in other fishes. Most people mistake the flat sides for the back and belly, but an examination will show that the paired breast-fins exist one on each flattened surface or side, whilst the dorsal and anal fins fringe the back and lower surface of the body respectively. These fishes swim on the light-coloured side; and both eyes, through a curious malformation of the bones of the skull, come to exist on one side of the body. The two sides of the mouth are of unequal size.

Flatt'ery, Cape, the name of two headlands—(1) One in the territory of Washington, U.S., on the S. side of the entrance to the Strait of Juan de Fuca. (2) One on the N.E. coast of Queensland, about 30 miles N. of Endeavour Bay.

Flat'ulence (from Lat. *flatus*, 'a breathing or blowing'), distension of the stomach or bowels by the formation of gases during digestion, depends more upon a disordered condition of the alimentary canal than upon the nature of the food partaken of. F. may be relieved by the use of aromatic medicines, such as anethi, carui, cinnamon, peppermint, cloves, ginger, cardamoms, &c.

Fla'vine is the name given to certain commercial colouring matters obtained from quercitron. The name is also given to a totally different substance, the diphenyl urea, $CON_2H_2(C_6H_5)_2$.

Flax (*Linum*), a genus of Exogenous plants belonging to the natural order *Linaceæ*. It has five imbricated sepals and five contorted petals. The ovary has five divisions, each of which is subdivided by a false septum or partition. The plants of this order are herbs with entire, sessile leaves. They are found in various quarters of the world, but most commonly in Europe and N. Africa. Common F. (*Linum usitatissimum*) is the best-known and most celebrated species. It grows as a smooth annual with a fibrous root, and attains a height of about two feet. The flowers are blue. At the present time F. is cultivated in Europe, Egypt, and India. F. is the Hebrew *pishtah* of Exod. ix. 31, the *linon* of Matt. xii. 20. The seeds are dark brown and of oblong shape, averaging about one line in length. A variety of the common F. named *L. humile* is grown to a large extent on the Continent. The F. plant becomes commercially of importance not only from the uses of the fibrous or woody tissue, obtained from the inner bark, in the manufacture of linen, but also from the drying oil expressed from the seeds, and known as 'linseed oil.'

Flax.

The crushed seeds form the 'oil-cake' so largely used in feeding cattle, and 'linseed meal' is obtained by grinding the crushed seeds after the oil has been expressed. Mixed with lime-water, linseed oil forms the 'carron oil' employed in the treatment of burns. 'Tow' is the product obtained in the process of 'heckling' the F. fibres. *F. cotton* is formed by steeping F. fibre, first in a solution of bicarbonate of soda, and then in a weak acid solution, so as to separate and break up the fibres to form a substance used in cotton manufacture. F. has been cultivated from the earliest times of which we have any authentic record. Thus F. linen was used to swathe the mummies of Egyptian tombs, and Herodotus refers to the extent of the Egyptian F. trade. In Ireland, F. is much more extensively grown than in England and Scotland, and in Belgium is cultivated to an extent probably unequalled elsewhere. *Brussels lace* is made from a fine F. grown in both W. and E. Flanders, and which sells at prices varying from £100 to £180 or more per ton. In 1849 Britain imported 1,806,786 cwts. of foreign-grown F., and in 1868, 1,816,669 cwts. of both dressed and undressed F. were imported from Russia, and other European countries, and from Egypt. In India F. appears to be grown chiefly for the seeds, which afford oil. When sown thickly, the F. plant yields the finest fibre, as also when the plants are pulled before the ripening of the seed. The name *purging F.* has been given to the *Linum catharticum* from its purgative properties. The latter is common enough in Britain, but is only used in popular and herbal systems of medical treatment.

Flax'-Dressing. The fibre of the flax plant is prepared for the spinners' use by the processes of seeding, steeping, rolling, drying, stacking, breaking, and scutching. Seeding is effected by quickly drawing the flax straw between two iron rollers, so fixed as to press out the seed without injuring it. An iron comb, called a ripple, with long and closely-set teeth, was formerly used for removing the seed-bolls. Steeping, or water-retting, is carried on by immersing the flax in a stream or pool of water. Fermentation ensues, and the glutinous matter which binds the fibre to its woody core is decomposed, facilitating the separation of the fibres. In Continental countries the flax is often sparsely spread on the ground, and exposed to the decomposing influence of dew and rain. This practice is distinguished as dew-retting. Im-

proved methods of retting, by which a great saving of time is effected and the work more efficiently accomplished, are general. Schenck's plan was introduced into Ireland in 1847. The flax is placed in vats containing water, the temperature of which is raised to and maintained at 90° by means of steam-pipes placed under a perforated false bottom. The average duration of steeping by this method is sixty hours. On the removal of the flax from the vats it is passed between heavy cylinders on which a copious supply of water falls. By this rolling residual impurities are extracted and the fibres further loosened. Atmospheric drying follows, and then the straw is sheaved and stacked for two or three months to improve its quality and facilitate cleaning. Breaking and scutching, by which the fibres are cleaned of the woody part of the stem and separated from each other, are next proceeded with. On the successful performance of these operations chiefly depends the value of the flax. Breaking and scutching machines of varied construction are everywhere superseding manual labour. The woody part is crushed by passing the straw between fluted rollers, and then in the scutching machine the fibres are freed from the broken wood by beaters or brushes. The flax fibre is much injured in the last machine, which causes the production of an excessive quantity of tow. See LINEN MANUFACTURES and SPINNING.

Flax'man, John, a great English sculptor, born at York, July 6, 1755, was the son of a figure-moulder of the Strand, London, in whose studio he learned to draw and model, entered the Royal Academy, and exhibited a figure of Neptune in wax in his fifteenth year. He married in 1782, and in 1787 set out for Italy, where he executed his fine series of illustrations for the Iliad and the Odyssey, the beautiful marble group 'Cephalus,' 'Aurora,' &c. Returning to London in 1794, he was elected R.A. in 1800, and Professor of Sculpture in the Royal Academy in 1810. He died December 7, 1826. In his series of 109 illustrations of Dante he established his fame as a designer of noble conception and exhaustless invention. His numerous mural works, many of them in Westminster Abbey, and all inspired with noble simplicity and elevation of feeling, constitute F. one of the chief authors of the Renaissance of rilievo. Of his monuments, those in memory of Sir W. Jones (University College), Sir F. Baring's family (Micheldean church, Hants), Countess Spencer, and Mrs. Tighe, are among the most famous. A valuable collection of the models of many of his chief works may be seen in the Flaxman Museum, University College. See Flaxman's *Classical Compositions*, *Illustrations of Dante*, and *Acts of Mercy* (Bell & Sons, Lond. 1875).

Flax, New Zealand. See PHORMIUM.

Flea (*Pulex*), a genus of Insects belonging to the Holometabolic section of the class, and to the order *Aphaniptera* ('hidden winged'). They undergo a complete metamorphosis, but have no wings, these being represented by certain of the plates upon the thorax or chest-segments. The mouth is adapted for suction. The fleas, of which the common F. (*Pulex irritans*) is an example, are parasites. The larvæ first appear as footless grubs, which pass into a quiescent state within a cocoon in about twelve days. They emerge from the cocoon in about fourteen days. The F. bites sharply, and is exceedingly active in its movements, the legs being very long. The parts of the mouth are modified so as to provide the creature with a set of instruments admirably adapted for piercing the skin of the animals upon which it resides. Another and much more important species of F. is the Chigoe (q. v.) or *Pulex penetrans* of the W. Indies. Fleas have sometimes been trained to perform amazing feats, such as drawing miniature carriages to which they have been attached.

Flea'bane (*Pulicaria*), a genus of Dicotyledonous plants belonging to the natural order *Compositæ*, and so named from its strongly aromatic smell having been supposed to be serviceable in exterminating fleas and other insect pests. The *P. dysenterica*, a familiar species, commonly found in damp places, derives its specific name from having been used as a remedy for diarrhœa and dysentery.

Flèche, La (Fr. 'the spire'), a town of France in the department of Sarthe, on the right bank of the Loir, 24 miles S.S.W. of Le Mans. The church of St. Thomas, whose 'spire' gives name to the place, is a Romanesque structure of the 11th and 12th centuries. The College of Jesuits, founded by Henri IV. in 1603, is now the famous Prytanée, a military school, with accommodation for 800 pupils. In one of the squares of the town is a bronze statue of Henri IV. The principal manufactures are cloth, paper, hosiery, and glue; there are flour and bark mills, and quarries of tufa. There is a trade in cereals, wines, and fruits. Pop. (1872) 6542.

Fleck'noe, Richard, was a dramatist of the 17th c., who seems to have been originally a Roman Catholic priest, and to have come from Ireland to seek his fortune in London by his pen. F., who died about 1678, wrote a number of plays, including *Demoiselle à la Mode*, *Love's Dominion*, and *Marriage of Oceanus and Britannia*, all of which are now forgottten, and some fugitive verses which Southey has praised. F. is best known by Dryden's satire of *Mac Flecnoe*.

Fleet (Old Eng. *fliet*, 'what floats,' 'a ship'), now denotes a collection of vessels, but is generally applied to war-ships. The collective F. of a country is spoken of as its navy. The different divisions of this are known as 'fleets,' each being under the command of an admiral.

Fleet Prison, or **The Fleet,** for centuries a notorious London jail, stood on the E. side of Farringdon Street, on the banks of the Fleet stream, formerly a rapid affluent of the Thames, and now embraced within the system of the sewage of the city. It was king's prison and also debtors' prison from before the commencement of the 13th c. Here the religious martyrs of the reigns of Mary and Elizabeth were confined, and later the victims of the Star Chamber. The building was several times renewed. It was destroyed in the great fire of 1666, again burnt by the Gordon rioters in 1780, and finally abolished in 1845 as a public nuisance. It was the scene of much irregularity and brutality, arising mainly from the extortions of the keepers, and of the *Fleet Marriages*, which were contracted chiefly from the middle of the 17th to the middle of the 18th c. Prior to the passing of the Marriage Act of 1754, all that was required to render a marriage valid in England was the verbal and expressed consent of the parties; and as the Fleet at the time contained a number of dissolute ex-parsons, who were ready to celebrate a secret marriage for half-a-crown, or, according to Pennant, 'for a dram of gin or a pipe of tobacco,' persons wishing to marry, yet to keep their marriage secret, flocked to the Fleet. The Marriage Act of the 27th March 1754 put an end to the trade of the Fleet parsons.

Fleet'wood-on-Wyre, a seaport in Lancashire, at the mouth of the Wyre, 18 miles N.W. of Preston by rail. It is a handsome modern town and a favourite watering-place. The chief buildings are the Whitworth Institute, the market-house, St. Peter's church, and the Roman Catholic church. F. has spacious barracks, and a fine harbour. Imports (1876), £162,948; exports, £507; customs, £823. In October 1877 the Lancashire and Yorkshire Railway Company opened a new dock and large timber pond at a cost of £300,000. Pop. (1871) 4428.

Flem'ish Language and Literature. The name Flemish is now limited to the Germanic dialect of Belgium, though modern Dutch and Flemish, or *Vlaemish*, were at first the same tongue. The present Flemish speech differs from Dutch only in having fewer guttural sounds, and in having borrowed a number of French idioms; but while it has, until late years, received little cultivation, and been used almost solely for popular tales, songs, and farces, in Holland the old *Vlaemish* has long been a literary tongue under the distinct name of *Dutch*. By Flemish is now meant the language of Flanders, N. Brabant, and part of S. Brabant—the *Walloon*, a French dialect, prevailing in Walloon Brabant, Liége, Namur, and part of Limburg. Under FLEMISH LITERATURE, however, must be included the early writings in *Flemish*, whether produced in what is now Holland or in what is now Belgium, while the modern Dutch literature from the 16th c. onwards will be treated under LITERATURE OF THE NETHERLANDS. Among the earliest relics of Flemish are three works of the 12th c., *De Trojaensche Oorlog*, a poem of above 3000 lines on the siege of Troy, by Dieregodgaf; the *Reis van Sinte Brandaen*, a wild monkish tale of the wondrous adventures of St. Brandan, full of fantastic inventiveness; and *Reinaert de Vos*, a version of the famous satirical poem *Reynard the Fox*, written, according to Willems, most probably about 1170. To the 13th c. belong the poets Melis Stoke, Jan van Heelu, Heijnric van Holland,

Willem Utenhoven, and Jacob van Maerlent, 'the father of Dutch poetry.' The civil wars of the 14th c. checked the growth of literature, but chivalrous tales, borrowed largely from France, such as *The Holy Grail*, *Lancelot*, *Roland*, &c., became popular, and in 1394 the first of the *Kamern der Rederijkern*, or Chambers of Rhetoric, was founded. These *Rederijkern* were institutions corresponding to the guilds of the German *Meistersingers*, which offered prizes for poetic competitions, and gave public representations of farces and *Spelen van Sinne*, or moralities. They were founded in imitation of the French *Colléges de Rhétorique*, and had a baneful effect on the purity and correctness of the Flemish tongue. As their members were chiefly mechanics, though at first many of them were *sprekers*, or vagrant minstrels, they kept alive a taste for literature among the lower classes, but flooded the language with corrupt phrases, and rendered its grammar lax and uncertain. The lampoons and satiric dramas produced under their influence partly fulfilled the censorial functions of the modern press, and at times displayed an almost Aristophanic heartiness and extravagant vigour of ridicule and rebuke. Among the peculiar forms of poetry developed by the Rhetoricians were the *ketendichten*, 'chain-poems,' in which the last word of each line rhymed with the first word of the following; *dobbelsteert*, 'double tail,' in which each line ended with a double rhyme; and *scaekberd*, 'checker-board,' poems of sixty-eight rhyming lines, so arranged as to form in every direction a strophe of eight lines. From the 14th to the end of the 16th c. was the age of the Flemish ballads and popular songs, many of the latter being religious, and comprising Christmas carols, *Ave Marias*, Easter hymns, the ballads of Sister Bertha, &c. In the 16th c. Holland, after its struggle with Spain, continued to produce a national literature, whilst the Flemish literature died away in the Belgic provinces. In the 16th c. the Flemish language received a large French infusion, and after 1694, when the French invaded Belgium, French for a time superseded Flemish in the journals, and even in polite conversation. After the annexation of Belgium by Holland, the Dutch efforts to conciliate the Flemings by favouring the Flemish language were very coldly received, and tended on the whole to strengthen a reaction against the old dialect; until, after the separation of Belgium from Holland in 1830, a strong Flemish movement, headed by Willems, arose. Since then a Flemish literary school has developed, of which the chief representatives are Willems, Van Ryswick, Van Deyse, Snellaert, Snieders, and Conscience, several of whose works have gained a European fame. The most elegant of Belgian periodicals, the *Nederduitsch Tijdschrift*, founded in 1862, is composed in Flemish. The chief Flemish authors have now agreed to write Flemish with the same orthography as the Dutch. See Vandenhoven, *La Langue Flamande, son Passé et son Avenir* (Brux. 1844).

Flemm'ing, Paul, a German poet, born at Hartenstein, Schönburg, October 15, 1609. He studied medicine at Leipsic, accompanied legations to Russia in 1633 and to Persia in 1635–39, and died at Hamburg, April 2, 1640. F. belonged to the first Silesian school founded by Opitz, and his works, *Geistliche und weltliche Poemata* (Jena, 1642; new ed. by Lappenberg, 1865), were unequalled by any German poet of the 17th c. They are vigorous and graceful in expression, lofty in thought, and full of interesting allusions to F.'s times. F.'s noble hymn *In allen meinen Thaten* is still sung in German churches. A selection of his poems was published by Schwab (Stutt. 1820), accompanied with a memoir of the poet's life. See also Varnhagen von Ense's *Biographische Denkmäler* (4 vols.) and Lappenberg's *Lexicon Hamburger Schriftsteller* (2 vols. Hamb. 1855).

Flens'borg, an old town in the province of Slesvig-Holstein, Prussia, on the F. Fjord, 20 miles N. of Slesvig by railway. It is the chief trading town in Slesvig, and has four steam and six wind mills, large breweries, and iron-smelting works, five brandy distilleries, a paper factory, and shipbuilding yards, besides manufactures of machinery, glass, soap, colours, tobacco, &c. In 1871 there cleared the harbour 1596 sailing and steam vessels of 471,660 tons, with cargoes. Pop (1872) 21,785, of whom 1635 were soldiers. F. is supposed to have been named from the knight Flenes, who is said to have founded it in the 12th c.

Flers, a town of France, department of Orne, on an affluent of the Noireau, 35 miles W.N.W. of Alençon, has cotton, linen, and other weaving manufactures, of the annual value of nearly £3,000,000 sterling. Pop. (1872) 7983.

Flesh, Chemical Composition of. F. or muscular fibre is composed mainly of fibrine in the coagulated condition, owing to the supply of blood constantly saturating the capillaries. Ordinary F. contains a certain quantity of that fluid, and therefore of its peculiar constituents, whilst in the juice which may be expressed from F., and which forms at least three-fourths of its weight, are found phosphoric, lactic, and butyric acids, partly in the free state, partly combined with potash and soda, lime and magnesia; chloride of sodium or common salt is also present. The juice of F. also contains a peculiar saccharine substance termed *Inosite* (q. v.), and an azotised body having feebly basic properties called *Creatine* (q. v.). The composition of muscle has been given as follows:—

Water	74·0	80·0
Solid constituents	26·0	20·0
	100·0	100·0
Albuminous substances insoluble in water	15·4	17·7
Gelatine	0·6	1·9
Albuminates of soda coagulating at 113° F.	2·2	3·0
Creatine	0·07	0·14
Fat	1·5	2·30
Lactic acid	1·5	2·30
Phosphoric acid	0·66	0.70
Potash	0·50	0·54
Soda	0·07	0·09
Chloride of sodium	0·04	0·09
Lime	0·02	0·03
Magnesia	0·04	0·05

Flesh-Fly (*Sarcophaga carnaria*), a species of *Diptera* or flies, so named from their depositing their eggs in decaying animal matter, and from their larvæ feeding on like substances. These larvæ thus become useful in removing putrefying material. Linnæus said that three flesh-flies could devour a horse in less time than a lion—meaning that the various broods of larvæ, produced in large numbers, would in turn attack and devour quantities of the putrescent matter. The eggs are hatched within the body of the parent F.-F., and the pupæ or chrysalides are contained within the larval skin.

Fletch'er, Andrew, of Saltoun, a Scottish patriot and political writer, was the son of Sir Robert F. of Saltoun, where he was born in 1653. After travelling on the Continent, F. entered the Scottish Parliament as member for East Lothian in 1681, but having borne part in the opposition to James Duke of York, then Royal Commissioner in Scotland, he was compelled to retire to England, and thence to Holland. Shortly afterwards he was outlawed, and his estate confiscated, whereupon he threw himself into the patriotic intrigues of the English refugees in the Netherlands. F. returned to England in 1683, and there became intimately associated with the leaders of the malcontent party—the famous Council of Six. The discovery of the Rye-House Plot (1683) scattered this party, and F. again fled to Holland. In 1685 he came back to England as volunteer in the Duke of Monmouth's invasion; but having killed the Mayor of Lyme in a private dispute, he was forced to quit the expedition at its very outset. F. then served in Hungary with distinction against the Turks. On the revolution of 1688 he came over from Holland with William of Orange, regained his lands, and again sat in the Scottish Parliament. The failure of the Darien scheme, in which F. had been a prime mover, embittered him towards King William's government, and in the Scottish Parliament he spoke violently against the projected union between England and Scotland. After the Union F. retired from public life. He died in London in 1716. F. was a passionate lover of freedom, but though a republican, was even more opposed to democracy than to monarchy. His views are set forth in several tracts—*Discourse of Government with Relation to Militias* (Edinb. 1698); *Two Discourses on the Affairs of Scotland* (1698); his *Speeches in Parliament* (1703); and *Conversation on Governments* (1704). These were reprinted at London in 1737 as *The Political Works of A. F.* There is an *Essay on the Life of F.* by the Earl of Buchan (1792), See also Macaulay's *History*.

Fletcher, Giles and **Phineas**, poets, sons of Dr. Giles F., uncle of F. the dramatist. Giles, born in 1588, was educated at Eton and Cambridge. In 1610 he published *Christ's Victory*

and Triumph in Heaven and Earth over and after Death, a poem in an eight-line stanza. It is tedious and affected, but at times rises into lofty imaginative poetry. F. held the living of Alderton, Suffolk, where he died in 1623.—Phineas F. was born at Wanbrook, Kent, April 1582, was educated at Cambridge, obtained Hilgay Rectory in Norfolk, and died in 1650. His works include *The Locustes* (1627), a satire on the Jesuits; *Sicelides, a Piscatory;* and *The Purple Island*, a poem in ten cantos, in which the human body is allegorically described. It is written in a seven-lined stanza, and though grotesque and prolix, is smoothly versified, with rich descriptive and lofty moral passages. Like his brother, Phineas was an ardent disciple of Spenser. Quarles called him 'the Spenser of his age.' The poems of Giles and Phineas F. are contained in Anderson's *British Poets*, vol. iv.

Fletcher, John, one of the greatest of English dramatic poets, was born at Rye, Sussex, December 1579. He was the son of Richard F. who became Bishop of London, was sent to Bene't College, Cambridge, in 1591, and was left an orphan and in poverty on his father's death in 1596. Nothing is known of his life until 1607, when he produced commendatory lines on Jonson and the comedy of *The Woman-Hater*, in which he may have been assisted by Beaumont, with whom he formed the most famous of all literary partnerships. F. and Beaumont are said to have lived 'on the Banke side, not far from the Play-house,' and to have had even 'the same cloaths and cloake in common.' We know that F. was highly popular in the literary Bohemia of his times, with which he would be more closely connected than was his aristocratic associate. Beaumont died in 1616, and F. continued to write plays, alone or with other dramatists, until he was cut off by the plague in August 1625. Modern critics have sought to disentangle F.'s from Beaumont's writings; but while we know that a particular series of dramas was produced by F. after Beaumont's death, we must view with dubiety all attempts to separate the one poet's verses from the other's in the pieces of which it is certain that they were joint authors. Mr. Donne regards the problem of sifting Beaumont's writing from F.'s as insoluble. Professor Ward cannot trace any essential difference between the plays ascribed to both and those attributed to F. alone, while he can detect two styles in the plays written by F. along with another than Beaumont. The assertion that Beaumont merely pruned and chastened F.'s writings is contradicted by the verses of their contemporaries, and the plays (as *The Maid's Tragedy*) in which Beaumont unquestionably shared do not show calmer judgment than those written by F. alone. Dyce assigns the authorship thus:—By Beaumont and F.—*Four Plays in One, Wit at Several Weapons, Thierry and Theodoret, Maid's Tragedy, Philaster, King and No King, Knight of the Burning Pestle, Cupid's Revenge, Little French Lawyer, Scornful Lady, Coxcomb, Laws of Candy*; by Beaumont alone—*Masque*; by F. and Massinger—*False One, Very Woman*; by F. and Rowley—*Queen of Corinth, Maid of the Mill, Bloody Brother*; by F. and Shirley—*Noble Gentleman, Night Walker, Love's Pilgrimage*; by F. and Shakespeare—*The Two Noble Kinsmen*; and the remaining plays, except the *Nice Valour*, as to which he is uncertain, by F. alone. The plays of Beaumont and F. are marked by exuberant and fiery, joyous and wanton inventiveness, by unflagging dramatic interest, splendid rhetoric, and flowery poetic colour, and by a fascinating natural sportiveness which is found in no other Elizabethan writers. But they show little depth or subtlety of imaginative insight; they fail to portray intense passions; their characters are often weakened by the undue emphasis given to a leading quality; and their plots, though mostly woven with marvellous dexterity, are sometimes maimed and twisted to produce ingenious situations. So far as we can judge, Beaumont seems to have had the loftier tragic genius, F. the more active creativeness, the more sparkling wit, the nimbler and more versatile and graceful fancy. Beaumont's verse is more severe and simple than F.'s, which is distinguished by flowery volubility and liquid melody, by a sometimes too copious overflow of sweet and pellucid language. The comedies in which Beaumont seems to have especially shared display the parodistic vein and broad farce characteristic of Jonson, features absent from those pieces in which F.'s genius shines with the most brilliant and unborrowed lustre—his romantic comedies, plays which stand alone in our literature for a peculiar blending of varied qualities, for fluent grace of style, for tender sentiment brightened with dazzling wit, for delicate poetic beauties inwoven with humour and softly flushed with passion, for the captivating interest of the plot, and for the introduction of those pensive, aerial lyrics which are surpassed by Shakespeare's loveliest songs alone. See Dyce's edition of Beaumont and F. (13 vols. 1841–48); W. B. Donne's *Essays on the Drama* (1857); and Ward's *English Dramatic Literature* (2 vols. 1875).

Fleur-de-Lis (Fr. 'flower of the lily,' in Old English 'flower de luce'), the emblem of the French kings, whose royal banner, even in the time of the Merwings, seems to have been blue with gold lilies. Charles VI. is said to have reduced the number of lilies to three, as a symbol of the Trinity. There are many legends accounting for the adoption of the emblem; most probably it was at first meant to represent the head of a javelin, or it may owe its origin to the Frankish custom of placing a *reed* or *flag in blossom* instead of a sceptre in the hand of each newly-made king. In 1789 the F.-de-L. was displaced by the tricolour. During the middle ages the F.-de-L. was also the emblem of the Virgin, and was a favourite design on church decorations. See Rey's *Histoire du Drapeau, des Couleurs, et des Insignes de la Monarchie Française* (Par. 1837).

Fleuru's, a town in the province of Namur, Belgium, near the Sambre, 7 miles N. of Charleroi, and 2 N. of Ligny. Pop. (1873) 3823. An indecisive battle took place here between the troops of the Catholic League under Gonzalvo de Cordova, and those of the Protestant Union headed by the Dukes of Brunswick and Saxe-Weimar, 30th August 1622. F. was also the scene of the defeat of the Prince of Waldeck by the Duke of Luxembourg, 26th June 1794; and of a victory of Jourdan over the Allies, brought about by the bad strategy of the Prince of Saxe-Coburg, 26th June 1794.

Fleu'ry, André Hercule de, Cardinal, a French statesman and ecclesiastic, was born at Lodève, in Languedoc, June 22, 1653. He studied at the Jesuits' College, Paris, was made almoner to the queen of Louis XIV., and, in 1699, Bishop of Fréjus. He gave up his bishopric in 1715, became tutor to Louis XIV.'s grandson, afterwards Louis XV., and insinuated himself into that prince's favour. He was elected into the Academy in 1721, was admitted to the Council of State in 1723, and in 1726 became a cardinal and prime minister of France. His administration was tolerably successful. He strove to economise and lighten taxation, and at first sought to maintain peace at almost any cost, but sacrificed the freedom of the Gallican Church to Ultramontanism, and was nerveless and vacillating in his foreign policy. In 1733 the court party forced him into the war of the Polish succession, on behalf of Stanislaus Leczinsky, Louis XV.'s father-in-law. The struggle ended in 1736, and in 1741 F. was compelled by court influence to take part in the war of the Austrian succession. He died at Paris, January 29, 1743. F. was a well-meaning, benevolent, and peace-loving minister, but had not the energy needful in his position. He patronised learning, and added several valuable MSS. to the royal library. See St. Simon's *Mémoires*.

Fleury, Claude, Abbé, a French ecclesiastical historian, was born at Paris, 6th December 1640. He was educated at first for the law, and is said to have been one of the ablest advocates in the Parliament of Paris, but coming under the influence of Bossuet and Bourdaloue, took priest's orders, shortly after which he became tutor to the sons of the Prince of Conti. His legal knowledge was shown in 1674 in the publication of *L'Histoire du Droit Français*. Four years later appeared his translation in Latin of Bossuet's *Expositions de la Foi Catholique*, while between 1681 and 1683 he issued three little works, *Les Mœurs des Israélites, Les Mœurs des Chrétiens*, and *Le Grand Catéchisme Historique*. Through the influence of Fénelon F., who was a modest, amiable, and erudite man, was appointed first assistant tutor to the sons of the then dauphin, and subsequently confessor to the young king, Louis XV., as well as Prior of Argenteuil. The chief works written by F. during the latter part of his life are *Discours sur les Libertés de l'Église Gallicane*, published after his death, and his *Histoire Ecclésiastique* (1691–1720), published in twenty volumes. This work, in particular, has been much admired on account of its candour and impartiality, and F. himself, although a 'good Catholic,' was the reverse of a sectarian or a fanatic. He died

July 14, 1723. See Martin's *Œuvres de l'Abbé F.* (1837), to which there is prefixed an essay on his life and writings.

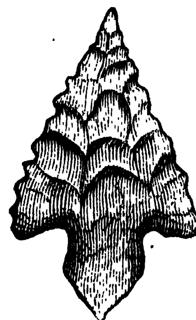
Fleu'ry, Flor'y, or Fleurett'ée, is applied in heraldry to an object of which the sides or ends terminate in *fleurs-de-lis*.

Flex'ure, in mathematics, is the bending or curving of a line or surface. A point of *contrary F.* or *inflexion* is the point at which a curve ceases to present convexity to a straight line without it, and begins to present concavity. Such a point cannot exist in curves lower than the third order. In engineering, F. denotes the bending of loaded beams, and is of great importance in the theory of construction. See STRENGTH OF MATERIALS.

Flied'ner, Rev. Theodor, D.D., a philanthropic clergyman, born at Eppstein, near Wiesbaden, January 21, 1800, studied at Göttingen, and in 1821 became pastor of a small Protestant community at Kaiserwerth, near Düsseldorf. F. is memorable as the founder of the Evangelical Deaconesses, who, though not a monastic body, correspond partly to the Catholic Sisters of Charity, visiting the sick and poor in their homes and in public institutions. F. laboured with great practical ability to organise these deaconesses, who have proved a boon to Germany, *e.g.*, in the Austro-Prussian war of 1866. Institutions modelled on F.'s establishment at Kaiserwerth have been founded at London, Paris, Berlin, Alexandria, &c. F. died at Kaiserwerth, October 4, 1864. See F.'s *Buch der Martyrer der evangel. Kirche* (1852), and Catherine Winkworth's *Life of F.* (Eng. trans. Lond. 1867).

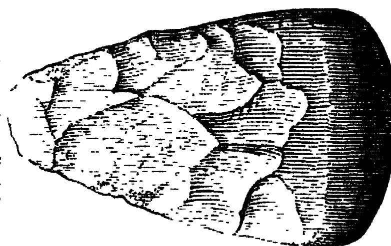
Flies, Spanish. See CANTHARIS.

Flin'ders, Matthew, discoverer of great part of the coast of Australia, born at Donington in Lincolnshire in 1760, entered first the merchant service, and afterwards the royal navy. In 1798 F., in company with Surgeon George Bass, left Port Jackson, New South Wales, sailed S. along a coast previously unknown, and discovered and named Bass Strait between the continent and Tasmania. Subsequently in 1801-1803 he explored all the southern, eastern, and northern coast of Australia from Cape Leuwen near its S.W. angle round by Bass Strait, and along by the F. coast, Gulf of Carpentaria, &c., to the island of Timor. The voyage was one of romantic adventure as well as of great geographical achievement. On the return voyage F. was seized and retained prisoner in the Isle of France for six years. He reached England in 1810, and died there in 1815. His *Voyage to Terra Australis* (1814) is a work of high interest.



Flinder'sia, a genus of Exogenous trees belonging to the natural order *Cedrelaceæ*, or that including the mahogany trees. F. grows in Australia, and its hard wood is extensively used as a substitute for mahogany.

Flint is a variety of quartz, allied to chalcedony, from the purer specimens of which it differs in having usually a dark-grey or even black colour, and in being but feebly translucent. It is massive and compact, and breaks with sharp edges and a conchoidal fracture. It is found as concretionary nodules in the chalk formations, and is probably organic in its origin, Ehrenberg supposing it to consist for the most part of infusorial remains. *Hornstone* or *chert* is very similar, but is more brittle, and occurs in the limestones of older formations. The hardness and sharpness of F. ensured its early use as a material for the manufacture of knives, chisels, rasps, axes, &c.; and the facility with which it strikes fire upon steel is well known, though now of little practical importance since the invention of lucifer matches and percussion caps.



Flint, a town in Flintshire 14 miles S.W. of Chester by rail, on the W. bank of the Dee. Its chief buildings are a modern Gothic church, the town-hall, and the national school. It is a favourite watering-place, has chemical works, and exports coal and lead, which are obtained near it. The trade has of late increased. Vessels of 300 tons can discharge at its wharf. To the N.E. of the town are the ruins of a castle built by Henry II. F. seems to have been a Roman station from the number of Roman remains, such as coins, amulets, brooches, &c., found in its vicinity. Pop. (1871) 4269.

Flint, a river in Georgia, U.S., joins the Chattahoochee after a course of about 300 miles, 250 of which are navigable for steamboats.

Flint Arrow-Heads, the commonest of the weapons of the Stone Age, occur abundantly in every country of Europe. They have been found also in Asia Minor and Palestine, in China and Japan, and in N. and S. Africa. They are plentifully distributed over the whole of the New World, and are still in use among the uncivilised tribes both of N. and S. America. Though varying greatly in form, they may be classified in three groups,—the triangular, the leaf-shaped, and the lozenge-shaped. The triangular group presents varieties, with or without barbs, with or without a central stem or tang, and sometimes with the base hollowed or notched for the insertion of the shaft. The leaf and lozenge shaped forms, of which there are many varieties, were destitute of barbs and tang. They were inserted in the split end of the shaft, which was finely tapered off, so as to embrace the arrow-head almost up to its point. The grip of the split shaft on the flint was tightened by a lashing of sinew immediately behind the arrow-head, and seems in many cases to have been further strengthened by the use of gum or bitumen. Arrow-heads vary greatly in size, there being in fact no distinction between an arrow and a spear or lance head except that of size. The smaller arrow-heads are often not more than a quarter of an inch in length, and they vary from this size up to the largest that a bow would carry. Whatever their size, they are always fashioned of chipped flint, and never finished by grinding, like axes and other such implements of flint of greater size. They are, however, by far the most symmetrically-formed and exquisitely-finished specimens of the flint-worker's art. The smallest examples, though not much thicker than card-paper, will exhibit from thirty to forty facets, each of which represents a blow so skilfully delivered as to flake off a splinter from the surface without fracturing the flint or injuring the symmetry of the weapon. Although in all countries the general forms are much alike, there are special varieties which are characteristic of special areas. The triangular variety, with barbs and blunt-ended tang, is most abundant in N. Britain, while that with a notch in the base is most abundant in Scandinavia. In France, Italy, and N. Africa the form with a pointed tang is most common. In N. America the triangular form with side notches for the reception of the sinew by which they are lashed to the shaft is the prevailing variety. Only a very small proportion of the flint implements found in the drift or in the cave-dwellings of England, France, and Belgium, and the kitchen-middens of Denmark, can be regarded as arrow-heads, but in the lake-dwellings of Switzerland they are very numerous and well made. They are frequently found in the dolmens or cairns and sepulchral deposits both of the Stone and Bronze Ages, but they are chiefly found casually embedded in the soil. It may be assumed that as arrow-heads of bronze are extremely rare, flint was used for this purpose throughout the Bronze Age as being the more accessible and less costly material. Among the savage tribes by whom it is still used, arrow-making is a work of skill in which only few attain excellence. Longfellow's description of the 'ancient arrow-maker' in *Hiawatha* has made us familiar with a phase of the life of the Stone Age continued into our time, but which is now fast passing away. Not the least curious of the phenomena connected with this passing away of an ancient art is that which is exhibited, not by the barbarian, but by the cultured and civilised sections of humanity, in the translation of these once familiar objects from the region of common life into that of the supernatural. In most of the civilised countries of

Serrated Flint Arrow-head

Flint Celt or Axe-head.

Europe F. A.-H. have been for many centuries associated with supernatural powers and regarded with superstitious veneration. Even among the Etruscans this feeling seems to have prevailed, for there is in the British Museum a beautiful gold necklace from an Etruscan tomb, the central pendant to which is a flint arrow-head.

Flint Glass. See GLASS.

Flint Im'plements, the tools of times when the use of metal was unknown, or when it was too rare and costly to be applied to the commoner purposes of the useful arts, are found in every country of the world whose antiquities have been made the subject of special investigation. Not only do they occur in regions that had not emerged from barbarism in prehistoric times, but on the sites of the most ancient civilisations of historic times their occurrence bears testimony to a previous condition of undeveloped civilisation of which history knows nothing. They underlie the relics of the most ancient civilisations of Europe, Africa, and Asia, in Greece and Italy, in Egypt, in Arabia, Palestine, Asia Minor, Assyria, Babylonia, India, China, and Japan. In all countries where flint is naturally accessible, it has been used by preference for the manufacture of implements and weapons on account of the facility with which it may be flaked and chipped into the desired form. The flint tools of primitive times were principally knives, saws, scrapers, awls, axes or adzes, chisels and gouges. In the manufacture of the smaller tools a peculiar process was employed. A suitable block of flint having been selected, it was first split, and then by a series of sharp blows delivered on the fractured face of the flint long splinters or flakes were separated from the block or core in such a manner that the ridge formed by the meeting edges of the two flakes previously struck off formed the midrib or back-bone of the third. Each flake was thus triangular in section, and broad or narrow in the base opposite to the midrib, according to the purpose for which it was wanted. Knives were usually made of a long thin flake, the natural edge of which is keener than any that can be produced by grinding, so keen, indeed, that flakes of obsidian were used to shave with by the Spaniards in Mexico when their European razors went out of order, and Mariette Bey records that he once saw an Arab having his head shaved with a flint flake at Abydos in Upper Egypt. This natural edge, however, is extremely brittle, and flint knives which were intended to retain their utility, and were not merely made for the temporary occasion, were worked to a more obtuse edge than is obtained by the natural fracture. In rare cases, and probably for special purposes, the edge was ground. Practically owing to the roughness of the edge all stone knives are saws, but the true saws were beautifully and often very finely notched or toothed with the utmost regularity. Both knives and saws were small, not usually exceeding 3 or 4 inches in length. Sometimes they were set in handles of wood or stag's-horn. Specimens thus handled are found in the Swiss lakes. The 'scraper,' so called because a similar tool mounted in a bone handle is used to this day by the Eskimos for scraping the fat off skins, was made from a flake by trimming one of its ends to a semicircular bevelled edge like that of a 'round-nosed turning chisel.' Judging by the large number of these tools of all sizes, from a quarter of an inch to 3 inches in length and width, that are found on every site of human occupancy during the Stone Age, it is probable that they were used for a great many purposes in which scraping or planing was required, including the manufacture of implements of bone or wood, as well as the preparation of skins for clothing. It is also probable that many of them were used as strike-lights with iron pyrites, nodules of this substance with the marks of use having been found in barrows in association with 'scrapers' of flint. Another form of 'scraper' with a semicircular hollow was used for planing arrow-shafts. Flint axes and adzes are sometimes merely chipped into shape, but more frequently they are ground sharp and smooth at the cutting edge, and occasionally smoothed or polished over the whole surface. They are extremely variable in size, ranging from 2 or 3 inches in length to as much as 14 or 16 inches in length. Axes or adzes were often made of other materials than flint, such as diorite, nephrite, greenstone, basalt, limestone, porphyry, serpentine, jasper, sandstone, and clayslate. Some of the modern savages, as those of New Guinea and the Barbadoes Islands, &c., make their axes of a large shell, extremely dense in texture. Chisels and gouges of flint are usually polished. They are well-made and effective tools, varying from 4 to 6 or 7 inches in length, and are most common in Scandinavia. Awls and borers are of various forms and sizes, but usually with a flattened shoulder or butt to be held between the finger and thumb. The most curious of these are the flint drills for piercing the 'eyes' of the bone needles found in the French caves. Besides the 'implements' properly so called, because their purpose is apparent from the form and finish that have been given to them, there is a class of 'F. I.' so called because they are artificially shaped, although they are so destitute of indications of destination or design, that it is impossible to suggest any special purpose of practical utility for which they could have been intended. They are usually found associated with remains of animals that are either totally or locally extinct, such as the mammoth, rhinoceros, lion, hyæna, reindeer, Irish elk, &c., and on this account, as well as from their rudeness of form and finish, an extremely high antiquity has been claimed for them. See Evans' *Ancient Stone Implements of Great Britain* (Lond. 1872); *Primitive Inhabitants of Scandinavia*, by Sven Nilsson, translated by Sir John Lubbock (Lond. 1868); Stevens' *Flint Chips, a Guide to Prehistoric Archæology*, &c. (Lond. 1870); *Catalogue of the National Museum of the Antiquaries of Scotland* (Edinb. 1876).

Flint'shire, a maritime county in N. Wales, bounded on the N. by the Irish Sea, on the E. by the Dee, and on the S. and W. by Denbighshire. Area, 288·9 sq. miles; pop. (1871) 76,312. F. chiefly consists of uplands, with hills of moderate height, the loftiest point being Moel-y-Famma, 1845 feet, in the S.W. The coast is low, and mostly sandy, but there are rich meadows on the estuary of the Dee. Many rivers, as the Elwy, Terrig, and Wheles, rise in F., but have their course chiefly in other counties. F. belongs mainly to the New Red Sandstone and Carboniferous formations, and has rich measures of coal, which are largely worked, and veins of iron, lead, and copper. Corn, barley, and green crops are grown in the plains and vales, and the uplands afford excellent pasture. The chief industries are mining, metal-working, and agriculture. There are also cotton manufactures. The principal towns are Mold (the county town), Flint, Holywell, and St. Asaph. F. returns two members to Parliament.

Flint'y Slate, a smooth, hard, brittle, splintery black rock, the result of the metamorphosis of slate or clay by contact with a mass of igneous rock. Rocks of this nature are found in the Lower Silurian of the S. of Scotland; and Lydian stone, used as a touchstone for testing precious metals, is probably of the same origin.

Float'ing Batt'ery, a name given to large vessels or hulks heavily armed and made as far shot-proof as possible. They were not built so as to attain high speed, or to be adapted for general service at sea, their principal use being in sieges, where rapidity of movement was not required. Wooden floating batteries were used against us by the French and Spaniards in the siege of Gibraltar (1779-80), and we employed iron ones—as did also the French—with success during the Russian war. Floating batteries are now superseded by armour-clad steamships, which unite a far greater degree of invulnerability than the others, with a speed such as the fastest cruisers scarcely ever attained.

Floating Docks. See DOCK.

Floating Islands may be formed either by nature or art, and consist mainly of masses of buoyant spongy soil, held together by the tenacious roots of plants. Portions of river banks are occasionally torn away by floods or swift currents, and carry with them to the ocean trees, reptiles, birds, and even large animals. Such 'straggling plots' are sometimes seen as far as 100 miles from the mouth of the Ganges, and were observed issuing from the Mississippi during the floods of 1874. F. I. have thus doubtless played an important part in the distribution of animal and vegetable life. Natural F. I. occur in great numbers in the marshy lakes bordering the Gulf of Venice. The lake of Gerdau, in Prussia, contains one of the largest in the world, while that in the lake of Kolk, in Osnabruck, is clad with elms. In Derwentwater, Cumberland, there is a small island which sinks below and rises to the surface of the water periodically like the fabled island of the Cutilian waters. This phenomenon is explained by the island rising only when the

Catgill, a stream which here enters the lake, is flooded by rains. The most celebrated artificial F. I. are the *chinampas* of the native Mexicans, and the aquatic gardens of Kashmir.

Float'stone, a light spongy-like variety of fibrous quartz, capable of floating on water, and occurring as flint incrustations in the limestones of the Paris chalk formations.

Flodd'en, Battle of, was fought on September 9, 1513, when James IV. of Scotland, who had sided with Louis XII. of France against Henry VIII. of England, was defeated by the Earl of Surrey, at F. Hill, one of the Cheviots, in Northumberland. There were about 30,000 on either side, and the Scots lost 10,000 men, among whom were James and the flower of his nobility. Miss Jean Elliot's exquisite ballad the *Flowers of the Forest* ('I've heard the lilting at our yowe-milking') is a lament for the calamity. The battle is described with more than Homeric fire and brilliancy in the 6th canto of Scott's *Marmion*. See Burton's *History of Scotland*, chap. xxx.

Flogg'ing, in the British army, is mentioned 'as strappadoe for drunkenness on guard' in the articles of war put forth by Charles I. in 1629, by advice of the council of war for the government of the troops in England. In every market there was to be a strappadoe as well as a gibbet. In the codes of 1639 and 1642 ordinary whipping by the provost is distinguished in the list of punishments. These codes also contained what was afterwards called by soldiers the 'devil's articles,' viz., for punishing indefinitely crimes for which no special order had been set down. In 1666 a jurisdiction in offences involving neither life nor limb was given to the then created regimental courts, which had also a power of 'arbitrary correction.' In 1672 'running the gantlet' was added. The Mutiny Act of 12 Anne confers on courts-martial a power to inflict corporal punishments 'for immorality, misbehaviour, or neglect of duty.' The disgraceful Act of 1715 declared every offence to be capital, with a discretion to the court-martial to award such other punishment as they should think proper. In 1812 both Houses of Parliament accepted the principle that for minor offences imprisonment might be inflicted as an alternative for corporal punishment, and the limitation of 300 lashes was introduced. A keen controversy raged down to 1868, when by 31 Vict. c. 14, sec. 22, the power to sentence any soldier to corporal punishment for any offence whatever during time of peace in her Majesty's dominions was abolished. But corporal punishment may be inflicted during active service or on board any ship not in commission for mutiny, insubordination, desertion, drunkenness on duty or on the line of march, disgraceful conduct (including embezzlement, theft, malingering, maiming, or tampering with the eyes), or any breach of the Articles of War, no punishment to exceed fifty lashes, or where punishment is also awarded, twenty-five lashes. This applies only to private and non-commissioned officers. In carrying out this sentence, the culprit is tied to a gun-wheel or a triangle of wood. For this purpose halberds were once used, hence the expression 'bringing a man to the halberds.' The drummers of infantry, and the trumpeters or shoeing smiths of cavalry, are selected for the work. The cat-o'-nine-tails consists of a drumstick with nine ends of whipcord, 16 inches long, and with three knots each. Steeping the cats in brine has been made the subject of a serious charge, and in the case of Governor Walls (28 *State Trials*), where a rope had been used, there was a conviction for murder. The barbarous practice of having right-hand and left-hand drummers is discontinued.

The law of F. in the navy during service is contained in the following passage of the Queen's Regulations :—'It being requisite for the maintenance of the efficiency, discipline, and even safety of H.M. ships of war, that the power of inflicting corporal punishment, when absolutely necessary, should be continued, such punishment is only to be inflicted under the responsibility and authority of the officers in command of the said ships, who are to exercise the power vested in them with the greatest discretion and forbearance.' No officer is subject to F., and petty or non-commissioned officers only in case of mutiny. Except also in case of mutiny, every soldier before sentence to F. is entitled to have an inquiry by one or more officers. But as regards marines during peace the prohibition of F. mentioned above in the case of the army is also inserted in every year's Marine Mutiny Act since 1868. The limit of punishment had previously been fixed at forty-eight lashes. In certain cases the possession of a good-conduct badge of the first or second class protected even common seamen against F. In all cases, of course, the man's health is looked to. Under the Juvenile Offenders Act, boys not older than fourteen may be sentenced to receive twelve strokes from the birch-rod.

Flood'ing is a term popularly applied to those copious hæmorrhagic discharges which occasionally occur after or during delivery. F. is caused by the non-closure of the uterine vessels, after the partial or complete separation of the placenta from the uterine surface, and the condition depends on the absence of contractile power in the uterus. F. very frequently follows abortion; and when such occurs during the early months of pregnancy, it is attended with great danger. Treatment :—procure delivery as early as possible, by exciting uterine action by means of friction and pressure, or by the administration of Ergot (q. v.).

Floor'cloth is generally formed of strong canvas oil-painted on both sides. (See LINOLEUM and KAMPTULICON.) The canvas is chiefly woven in Dundee in pieces of great length and width. The manufacture of F. is begun by stretching a piece of canvas containing about 210 or 220 sq. yards upon a vertical open wooden frame, a series of these frames being arranged parallel to each other at a distance of 30 inches with a tiered scaffolding between them, to enable the workmen to reach every part of the canvas. The cloth is washed on both sides with weak size, and then smoothed with pumice. This 'priming' solution preserves the pliability of the cloth by filling up the meshes to the exclusion of the oil-paint, which is next applied in the form of one 'trowel' and one 'brush' colour to the back, and afterwards of three coats of 'trowel' and one coat of 'brush' colour to the face. Each layer of paint, when dry, is rubbed down with pumice. The 'trowel' colour is so called because it is worked over the canvas with a trowel-shaped implement, the thick consistence of the paint not admitting of its being spread with a brush. When thoroughly dry, the painted cloth is transferred to the 'printing-room,' where it is passed over a long narrow table, and a pattern is hand-printed on the face by means of wooden blocks. Each colour has a separate block, the impressions of all producing an appropriate and harmonious design. From two to three months are occupied in the production of good floorcloths. The full-printed cloths are hung up in 'drying-rooms' to mature and season. This measure imparts strength to the cloth and brilliancy to the colours. F. is extensively made at Kirkcaldy in Fifeshire. There, one establishment alone can turn out 20,000 sq. yards per week, or an annual production of over 1,000,000 sq. yards. Painted baize and other light fabrics for covering furniture are produced in a manner similar to F.

Floors, in houses, the horizontal partitions between the stories. In the common or 'single-joisted' floor, a series of parallel wooden beams are laid across from wall to wall; these are not less than 8 or 9 inches deep, and 2 inches thick, and commonly more, and are called *joists*. To the top of these the flooring, which consists of narrow planks placed close together, is secured, and underneath them the laths for receiving the plaster of the ceiling are attached. 'Double-joisted' and 'framed' F. are more complex in construction, and are used where for any reason special strength is required, or where the length of the room is very great. The space between the flooring and the ceiling should be filled as far as possible with cement or other substance, as 'deafening.' In this country the flooring is of soft wood, and is most frequently planed tolerably smooth and left in that condition. In most parts of the Continent, where carpets are not so much used as with us, the F. are of hard wood, carefully jointed and kept always polished. The floor thus made looks better certainly than nine-tenths of the carpets used in this country. It is both clean, convenient, and economical to stain and varnish the edge of a soft-wood floor for a distance of about 2 feet 6 inches from the wall all round, and to put a border round the carpet, making it cover only as much of the floor as is unstained. This method can be used in any house floored in the ordinary way, by having the small spaces too often left between the planks stopped first with brown putty.

Flo'ra, the goddess of flowers and spring, was worshipped at Rome from the very earliest times. Her festival, the Floralia, lasted five days, from April 28 to May 1, and was celebrated with great licentiousness. The later Romans identified F. and

Chloris, the Greek goddess of flowers. In botany the word denotes the vegetable kingdom. See FAUNA.

Flor'ence (Lat. *Florentia*, 'the flourishing;' Ital. *Fiorenza*, now *Firenze*, surnamed *la bella*), one of the largest and fairest cities of Italy, capital of the province of the same name, is built on both sides of the Arno, but chiefly on the N. bank, 50 miles from the sea, and is connected by rail with Bologna and Rome. Its environs are singularly beautiful. It lies in the leafy valley of the Arno, in a gently undulating country, amid low hills covered with vineyards and terraced gardens, with white villas and old towers embosomed in groves of olives, cypresses, and mulberries, while to the N. the Apennines rise to a height of 3000 feet. The central and oldest part of F. is a maze of narrow, gloomy streets, where the massive castellated palaces of the nobles, used as fortresses during the middle ages, may still be seen. The Borghi, or outer quarters, which intervene between this central part and the old walls, are more spacious and regular; and beyond the walls lie the modern suburbs, consisting almost wholly of villas set among gardens. F. has lately been much changed. A new suburb has been built on the E. of the city, with handsome squares and boulevards, and the old quarters have been pierced by wide streets. The Arno, now confined to a channel 100 feet wide, is lined by broad quays known as the Lung Arno, which form a fine promenade, with a view of the sylvan Valdarno at one end, and of the Vallombrosan hills at the other. The river is spanned by six bridges, of which the Ponte alle Grazie is the oldest, having been built in 1235 (restored 1835). The Ponte Vecchio, still covered with quaint shops, dates from 1362. The walls are dismantled of the seventy or more towers which once crowned them, but the old gates are extant, the most interesting being the Porta Romana, Porta S. Miniata, Porta S. Gallo, and Porta alla Croce, built in 1284, the two last displaying frescoes by Ghirlandajo. F. has above twenty squares, of which the chief is the Piazza della Signoria, once the forum of the Florentine commonwealth, and still the great seat of trade. It contains a large fountain with bronze statues by Gian of Bologna. F. is rich in graceful and imposing buildings, in picturesque and historical piles. The Duomo, or cathedral, which stands near the centre of the city, was begun by Arnolfo di Lapo in 1294, was continued by Giotto, and was finished by Brunelleschi in 1436. The dome is 384 feet high, and the walls are cased with marble. By the side of the Duomo Giotto's campanile, or bell-tower, rises to a height of 292 feet. It is covered with delicately-tinted marbles and Gothic traceries, and according to Ruskin is the one building which unites in the highest degree the characteristics of beauty and power. The church of Santa Croce, 'the Westminster Abbey of Italy,' possesses eleven chapels and the tombs of Michael Angelo, Alfieri, and Macchiavelli, while the church of San Lorenzo contains the tomb of the Medici and the statues of Giuliano and Lorenzo de Medici by Michael Angelo. The Palazzo Vecchio or Palazzo della Signoria, built in 1285 by Arnolfo, is a square turreted pile, and was once the seat of the republic's magistrates. It has a lofty tower with the great bell which formerly called out the citizens. The Palazzo degli Uffizi possesses a library of 150,000 vols. and 12,000 MSS., and an unsurpassed collection of sculptures and paintings, amid which are the Venus de Medici and the famed group of Niobe and her children. The Palazzo Pitti, begun by Brunelleschi, and the residence of the King of Italy when he is at F., has a library of 70,000 vols. and a magnificent collection of paintings. Near the Pitti Palace, and on the summit of a hill S. of the Arno, are the Boboli Gardens, with statued avenues, terraced walks, fine fountains, and trees cut into formal shapes. The Bargello, built in 1255 as the abode of the Podestà, and known as the Palazzo di Giustizia, but for centuries used as the public prison, has been of late carefully restored and transformed into a museum for Tuscan antiquities. It has seven great halls and a richly-carved marble staircase. The church of Or San Michele is one of the finest Florentine relics. It is adorned with statues by Ghiberti, Donatello, and Gian of Bologna, which stand in niches of white marble carved into fanciful arabesques and inlaid with gold mosaic. There are many other palaces and churches and several theatres and hospitals. The commercial greatness of F. has departed; the silk, velvet, and woollen manufactures have declined, and trade is now mostly in mosaics, jewellery, porcelain, and works of art, though carpets and straw hats are still made. F. has two forts, but no regular defences. Pop. (1874) 123,463. F. has been compared to Athens for the turbulence, intellectual brightness, and keen political sympathies of its inhabitants, for its firm democratic leanings, and for its splendour as a home of literature and art. It was the centre of the Renaissance in Italy, and the focus of Italian culture; it gave birth to the modern literary dialect of the Italian language, produced the earliest school of political historians since the days of ancient Greece, and numbered among its sons several of the greatest names in the history of painting, sculpture, and architecture. See RENAISSANCE, ITALIAN LITERATURE, and ITALIAN ART.

F. was founded by the Romans in the 1st c. B.C., was pillaged in the dark ages by the barbarians, and was afterwards occupied by the Lombards. Karl the Great appointed a duke, afterwards called a count, over F., with officers under him chosen partly by the people, a government which seems to have been the germ of the Florentine commonwealth. The emperors, especially Otho the Great, favoured the city, which in the 10th c. had conquered several neighbouring places. F. was ruled by twelve *Angiani*, acting along with a foreign Podestà, and no distinction was made between plebeians and nobles, until, between 1282 and 1292, a mercantile commonwealth was established. It was decreed that no one could bear office who did not belong to the *Arti* or commercial guilds, and the nobles were forbidden to share in the government, which was administered by eight Priors and the Gonfalonier of Justice. These held office for two months. About 1300 party strife broke out between the Guelphs, known as the *Neri* ('blacks'), and the Ghibellines or *Bianchi* ('whites'), the latter, among whom was Dante, being in the end banished. In 1323 the constitution was changed, and Guelph citizens above 30 were alone declared eligible for the chief magistracies, and were chosen by lot. During the 14th c. a new aristocracy grew up and the Medici came into importance. In the beginning of the 15th c. the Medici dynasty was founded by Giovanni de Medici (died 1428), who was succeeded by Cosmo; and Cosmo's grandson Lorenzo in 1480 overthrew the old democratic constitution in place of a Council of Seventy, through which he controlled the state. In 1494 Pietro Medici was banished, and Savonarola founded a theocratic commonwealth, which ended in 1498; then the old republican government was restored under Soderini until 1512, when the Medici returned to power. A free commonwealth again existed from 1527 to 1530, when the Medici despotism was forced upon the city by the Emperor Karl V. Up to this time the Medici had ruled as commercial tyrants without princely titles, but in 1532 Alessandro de Medici was made hereditary president, and Cosmo, his successor, was declared Grand Duke of Tuscany in 1569. On the extinction of the Tuscan ducal line in 1737 F. became the appanage of the house of Lorraine, under whom, except during the episode of Napoleon's kingdom of Etruria, it remained until 1860, when Tuscany was united with the kingdom of Italy. In 1864 F. succeeded Turin as capital of Italy, but was superseded by Rome in 1870. In history F. is remarkable for her general adherence to the Guelphic party, for the instability of her government as contrasted with the permanence of the Venetian rule, for the bright, variable political activity of her citizens, and for surpassing every other Italian city in her interest in the welfare of all Italy. See Délécluze, *F. et ses Vicissitudes* (2 vols. Par. 1837); Reumont, *Tavole Cronologiche e Sincrone della Storia Fiorentina* (8 parts, Flor. 1841); Trollope, *History of the Republic of F.* (Lond. 1864); Symonds's *Renaissance in Italy* (Lond. 1875).

Florence of Worcester, a monkish chronicler, belonging to Worcester monastery, where he died 7th July 1118. He wrote a chronicle from the Creation to 1117, compiled chiefly from the *English Chronicle* and the work of Marianus Scotus, with additions from Bede, the so-called 'Asser,' and the Lives of the Saints. His chronicle deals mainly with English history, but also notices events abroad. It was brought down to 1141 by others of the brethren.

Flo'res (Port. 'flowers').—1. The most westerly island of the Azores, in lat. 39° 25′ N., and long. 31° 12′ W. It is very fertile, and has a pop. of 16,522. The chief town is Santa Cruz. —2. The largest island of the chain extending E. from Java to Timor, lies 200 miles S. of Celebes. It is 200 miles long and

35 broad, is in great part hilly, and has several lofty volcanic peaks on its S. side. The exports are sandal-wood, beeswax, and horses. There are Malay settlements on the coast, but the natives are of Nigritic race.—3. An islet of Uruguay, in the Plata, 20 miles below Monte Video.

Flor'iculture, or **Flower-Cultivation,** the art of cultivating flowers for the sake of their beauty, odour, and uses, has been practised from the most ancient times. In ancient history special reference is frequently made to floral decorations and to the selection of flowers for various purposes; while in modern times, not only has the art of gardening become very highly developed, but from a knowledge of the physiology of plant-life, florists are enabled to cultivate flowers under much more favourable auspices than formerly. The art of landscape-gardening has in fact become of late years highly specialised. In great towns and cities especially, flower-growing has been much facilitated by the invention of the *Wardian case*, a closely-glazed case invented by Mr. N. B. Ward. It consists of a strong box or trough to contain earth, which is placed over a substratum of gravel and broken bricks. The soil is well watered, and over the box a glass roof of tight-fitting nature is placed, this glass roof possessing a door or aperture permitting the removal of dead leaves, &c. By means of this principle of isolating, as it were, plant-life from the surrounding atmosphere, and supplying delicate or exotic forms with the necessary conditions for growth, many plants of rare nature can be successfully grown even in a very smoky atmosphere. The cultivation of flowers for commercial purposes may be said to form the practical application of the art of F. Thus the cultivation of Lavender (q. v.) assumes a high importance from the uses of that plant in the manufacture of perfumes. At Mitcham in Surrey vast quantities of lavender are grown. Otto or attar of roses, valued in some cases at five guineas per oz., also exemplifies the extent to which the successful results of F. may be carried. See Thomson's *Handy Book of the Flower-Garden* (1868), and Glenny's *Flower-Garden* (1871).

Flor'ida, the most southern of the United States of America, included chiefly in the bold peninsula projecting from the S.E. angle of the country, is bounded on the E. by the Atlantic, on the W. and S. by the Gulf of Mexico, and on the N. by the states of Georgia and Alabama. Area, 59,268 sq. miles, or somewhat larger than England and Wales. Pop. 188,248. The peninsular portion is 90 miles broad and 370 miles long. The coast-line is over 1150 miles in extent, and among its numerous harbours some of the chief are Pensacola, St. Marks, Cedar Keys, Tampa, Charlotte, Key West, St. Augustine, and Jacksonville. The capital is Tallahassee. From Cape F., near the southern extremity of the peninsula, a great series of reefs or keys sweep round to the S. and W., and end in a group of sandbanks and islets called *tortugas*. The chief of the keys are Key Largo and Key West, on the latter of which the important city and naval station of the same name is placed. The *surface* is level, the highest elevation being a ridge 180 feet above sea-level, extending from Fernandina on the E. to Cedar Keys on the W. coast, and traversed by railway. Streams, lagoons, and marshes abound all over the country. The chief rivers are the St. John's and the Suwannee. In southern F. the land seldom rises to more than 6 feet above the level of the tide. The soil is usually a light sandy loam, with a substratum of clay, and is of all qualities from the sandy pine barrens to the swamp lands of tropical productiveness. Nearly all the grains and fruits of temperate regions may be grown in the N., semi-tropical fruits are profitably cultivated in the eastern and central districts, tropical fruits in the S. Raising cotton and sugar-cane, for which the soil and climate of F. are especially suitable, are growing industries. The forests consist of yellow pine, live oak, hickory, magnolia, mahogany, satin-wood, &c. Though in the same latitude as the Sahara Desert and S. China, the climate of F., tempered by cool winds from the seas surrounding it, which blow from sunrise to sunset, is delightful during the greater part of the year, and in this connection F. is becoming to the northern states of America what southern France and Italy are to Europe—a national sanatorium, and a favourite place of resort for those suffering from pulmonary diseases. Of the entire area of about 38,000,000 acres, 2,000,000 are under cultivation. The cultivation and export of oranges, lemons, and citrons is the chief industry. Besides the numerous orange-groves in existence in 1870, 3,000,000 orange-trees planted since then were bearing in 1875. In 1872 the cotton production was 47,125 bales. The Indian corn crop in 1873 reached 2,320,000 bushels, of Irish potatoes 13,000 bushels, of sweet potatoes 1,037,000 bushels, of sugar 1300 hogsheads, of molasses 500,000 gallons, of tobacco 200,000 pounds. Hallock states that F. may at no distant date grow fruit for half the world, if she can only obtain a sufficiency of capital and labour. *History.*—Ponce de Leon, in search of an El Dorado that contained also the Fountain of Life, landed here in 1513, and gave the country its present name—the land of flowers. It was settled by the Spaniards in 1565, ceded to Britain in 1763, re-ceded to Spain in 1784, sold to the United States in 1819, and constituted a state of the Union in 1845. In 1861 F. joined the Southern Confederacy, and was the scene of many bloody conflicts until 1865. In 1868 the state was readmitted into the Union. See Townshend's *Wild Life in F.* (Lond. 1875); Charles Hallock's *Camp Life in F.* (1876); Lanier's *F., its Scenery, Climate, and History* (Lond. 1876).

Florida-Blan'ca, Don Josefo Moñino, Count of, a Spanish statesman, born at Murcia in 1728. He studied law, became ambassador at Rome, where he ably composed many differences between Spain and the Pope, and was a chief agent in the election of Pius VI. In 1777 Charles III. made him prime minister, in which office he promoted trade and science, improved the roads and beautified the cities of Spain, and allayed a dispute with Portugal. He united Spain with Russia and Prussia in an armed neutrality, of which the aim was to cripple England, but his foreign policy ended in failure. During his administration Algiers was bombarded, which checked piracy, many heavy dues were removed, and great judicial reforms were effected. F. created many powerful enemies, and in 1792 was imprisoned in the castle of Pampeluna. After several years' confinement, he was permitted to return to Murcia, where he lived in retirement until 1808, when he was called to preside over the central junta during the war with Napoleon. He died at Seville, 20th November 1809. F. wrote several treatises on jurisprudence.

Flor'idæ. See CERAMIACEÆ.

Florida Gulf, between the peninsula of Florida and the Bahamas, is practically the local name applied to that reach of the Gulf Stream which skirts the S.W. coast of Florida. See CURRENTS, OCEAN.

Florid'ia, a town of Sicily, province of Noto, near the Alfeo, 7 miles W. of Syracuse. It has some trade in grain, wine, and olives. Pop. 7030.

Flor'in, at first the name of a gold coin, so called either because it was made at Florence, or because on its reverse side there was a lily (Lat. *flos*, 'a flower'). The modern English coin so designated is of silver, and of the value of 2s.

Flor'ists' Flowers. These flowers are so named from having been made the subjects of special attention by the practisers of Floriculture (q. v.). The cultivation of roses, dahlias, tulips, fuchsias, hyacinths, and many other flowers, exemplifies the results of the florist's art. The liability of many flowers when cultivated to *sport*—*i.e.*, to produce varieties—and the knowledge that by fertilising together flowers of different species, varieties can be produced in some cases almost at will, form two facts of great importance to florists. The fertilisation of the seeds of one species by the pollen of a different species tends to produce a union, in the hybrid progeny, of the characters of the parent-species. And hence the colours of flowers and other characters can be manipulated often with great freedom. *Double flowers* result from the conversion of the stamens and pistil into whorls of flower leaves—this process resulting in the sterility of these flowers. The Dutch have long been famous for their cultivation of flowers, particularly Tulips (q. v.). In 1636-37 a 'tulip-mania' seized Holland, and fabulous prices were given for rare varieties and bulbs. In S. Holland the cultivation of roses is also carried on with vigour, and in Britain, dahlias, hollyhocks, fuchsias, and other flowers are successfully grown.

Flo'rus, L. Annæ'us, or more probably **Julius,** the reputed author of a succinct but over-rhetorical history *Epitome Rerum Romanarum*, composed most probably in the reign of Augustus. It consists of two books, the first dealing with the foreign wars of Rome, the second with civil strifes, and ending at 20 A.D. The best editions are those of Otto Jahn (Leips. 1852), and of Halm (Leips. 1854). See Reber's *Das Geschichtswerk des F*

(Freising, 1865), and C. Heyn's *De Floro Historico* (Bonn, 1865).

Flo'tant (Fr. 'floating'), an heraldic phrase applied to an unfurled flag.

Flo'tow, Friedrich von, a living German composer, born at Teutendorf, in Mecklenburg-Schwerin, 26th April 1812. He received his musical education in Paris, where also his first successful opera, *Le Naufrage de la Méduse*, was produced in 1839. His compositions are all operatic; they are pleasant and melodious, and in many ways more like the work of a musician than those of his Italian and French contemporaries. While extremely popular, however, both in Germany and France, they are not yet, with the exception of *Martha*, so much known in this country as they deserve to be. The principal are *Stradella, Die Grossfürstin, Rübezahl, Indra, Albin, Hilan, and L'Ombri.* Since 1863 F. has lived in Paris.

Flot'sam is a term of English law denoting goods floating in the sea, or goods which have been cast on shore by the sea. Where the owners are not known, F. goes to the crown or lord of the manor. When the owners are known, they have a year and a day to claim their goods. See DERELICT, JETSAM, and JETTISON.

Floun'der (*Platessa*), a species of *Pleuronectidæ* or flatfishes, common on the coasts of Britain, and esteemed as a food fish. It is distinguished by possessing a single row of teeth, the dorsal fin commencing over the eye, and the tail fin being distinct. The common F. (*P flesus*) attains a length of 10 or more inches, and a maximum weight of 5 or 6 lbs. Smaller specimens, however, are more frequently met with. The eyes are on the right side of the body, this being the upper side of the animal, which swims and lies on the left side. Its colour is brown. The dab (*P. limanda*) is nearly allied to the F.

Flour, the grain of wheat or other cereals finely ground for human food. The term is also applied to many finely-powdered substances.

Flou'rens, Marie Jean Pierre, a French scientific writer, was born at Maureilhan, Hérault, April 15, 1794. He devoted himself from an early age to scientific study, at seventeen delivered a course of lectures on 'The Physiological Theory of Sensations,' and at nineteen obtained the degree of Doctor of Medicine, after which he went to Paris, where he made the acquaintance of St. Hilaire, Chaptal, the Cuviers, and other men of science. Admitted a member of the Académie des Sciences in 1828, he succeeded in 1832 to the professorship of natural history in the Jardin du Roi, and the following year became Perpetual Secretary of the Académie des Sciences. F. was a very voluminous writer, and from 1841 to 1851 published a number of books giving in a comprehensive form and in a singularly lucid style the 'history and philosophy' of several branches of science. Among his works are *Anatomie Générale de la Peau et des Membranes* (1843); *Théorie Expérimentale de la Formation des Os* (1847); and *De la Longévité Humaine et de la Quantité de Vie sur le Globe* (1854). F., who had been deputy to the French Chamber for Béziers, was made in 1840 a Peer of France, and in 1864 member of the Municipal Council of Paris. He died December 6, 1867.—**Gustave F.**, son of the above, and better known as a revolutionist than as a *savant*, was born August 4, 1838. In 1863 he filled his father's chair in the Collège de France, published (1865) *Science de l'Homme*, and aided in the preparation of a *Grand Dictionaire du XIX. Siècle.* From 1866-68 he took part in the Cretan insurrection, about which he wrote a book. On his return he threw himself into conspiracies against the Second Empire, aided the celebrated Rochefort in editing the *Marseillaise*, was wounded in a duel with the Bonapartist M. Paul de Cassagnac, and on being sentenced in 1870 to three years' imprisonment, fled to England. After the fall of the Second Empire, he became commander of a regiment under the Commune, and was killed April 3, 1871.

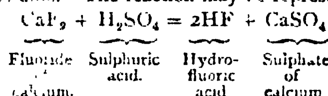
Flour-Mite (*Acarus farinæ*), a species of *Acaridæ* or mites which belong to the spider class (*Arachnida*). They exist among flour, and resemble in form the cheese-mite or *A. domesticus.* The body is oval, has eight legs, and is covered with bristles. The female flour-mites are larger than the males.

Flour, St. (the ancient *Sanctus Florus*, surnamed *La Noire*), a town of France, department of Cantal, 34 miles E.N.E. of Aurillac. It stands on a basaltic highland, and is built almost entirely of volcanic *débris.* Its chief buildings are the cathedral (15th c.), the church of St. Vincent, and the corn-market. F. has manufactures of copper utensils, and trade in cattle and corn. Pop. (1872) 4046.

Flower (from Fr. *fleur*, Lat. *flos, floris*), the name given to the conspicuous series of organs found in higher plants, the ultimate function of which is *reproductive* in nature, and serves to mature and produce *seeds.* A perfect F. consists of four *whorls*, or concentric series of organs. Externally we find (1) the *calyx* (usually green, but sometimes coloured), composed of certain leaves named *sepals*; (2) within the calyx, the *corolla*, or showy part of the F., composed of leaves named *petals*, and coloured to attract insects to the F., for the purpose of fertilising the pistil by the conveyance of the pollen, or matter of the stamens; (3) the *stamens*, forming the third whorl, and existing each as a *filament*, bearing a head or *anther*, consisting of two lobes, within which the *pollen*, a yellow powder necessary for fertilising the seeds, is produced; (4) the *pistil*, which is the central whorl of the F., and is composed of one or more folded leaves named *carpels.* Each carpel consists of a lower portion (the *ovary*, containing the *ovules* or *seeds*), of a neck (the *style*), and of a little head surmounting the neck, and named the *stigma.* The stigma and style may be wanting. The stigma is borne directly on the ovary (as in the poppy) when the style is wanting. The calyx and corolla are collectively named the *floral envelopes*; while the stamens and pistil are together named the *essential organs*, because they are necessary for the production of seed. Every part of the F. is a leaf more or less modified. The leaf-type of the F. may be demonstrated in cases of abnormal flowering, as in *double flowers*, where the stamens and pistil are represented by floral leaves. Conspicuous flowers are only met with in higher plants, which are hence named *phanerogamous.* In ferns, mosses, and lower plants, the reproductive organs are not conspicuous, and such plants are hence named *cryptogamous.* The F. is usually borne on a *peduncle* or F.-stalk. Where no F.-stalk is developed, flowers are said to be *sessile.* Thus in a daisy numerous sessile flowers are borne on a common receptacle, and form a F.-head or *capitulum.* When all four whorls of the F. are present, the F. is *complete.* It is *incomplete* if one or more are absent. When (as in lilies, tulips, &c.) the calyx cannot be distinguished from the corolla, or when one whorl only is present, the floral envelopes receive the name of *perianth.* A F. with calyx and corolla is said to be *dichlamydeous*; with one envelope only, *monochlamydeous*; and with no true calyx or corolla, *achlamydeous.* Flowers are *irregular* when one part of the calyx or corolla exceeds in size the other parts—as in the corolla of dead-nettle; and *regular*, when all the parts are of equal size—as in the buttercup. A F. is *symmetrical* when its parts exist in similar numbers or in multiples of one another. When flowers depart from the ordinary type of floral structure or arrangement, their modifications are due—(1) to the *absence* or *suppression* of one or more whorls; (2) to the *form* of the whorls; (3) to the *separation* or *union* of parts of whorls; (4) to the *parts* of one whorl being united to the adjacent whorl on either side; and (5) to the *position* of each whorl on the floral receptacle. Flowers are *bisexual* when each has both stamens and pistil. They are *unisexual* when each F. has one series of essential organs (stamens or pistil) only. Flowers are called *monœcious* when staminate or stamen-bearing flowers are situated on the same *plant* with pistillate flowers; and *diœcious* when staminate flowers are situated on one plant and pistillate flowers on a distinct plant. The *arrangement* of flowers on the flowering-axis is named *inflorescence.* Inflorescence is determined by the manner in which flowers open. Thus when the centre F. opens first, and the external flowers open later, the inflorescence is said to be *centrifugal* or definite; such a mode of F.-expansion is seen in buttercup, chickweed, sweet-william, &c. In wallflower, foxglove, &c., the inflorescence is *centripetal* or *indefinite*, the flowers furthest from the axis opening first. The most common arrangements of inflorescence are—(1) the *spike*, as seen in plantain, where numerous sessile flowers are arranged on a common axis; (2) the *raceme* (as in red currant, foxglove, &c.), which is simply a spike with *stalked* flowers; (3) the *capitulum* or *head* (as in daisy, clover, &c.), where sessile flowers are

arranged on a common receptacle; (4) *panicle* (as in oat, horse-chestnut, &c.), which is a compound raceme, each secondary F.-stalk or pedicel again dividing; (5) the *umbel* (as in cowslip, carrot, hemlock, &c.), where the pedicels or secondary F.-stalks spring from a common point, and bring the flowers to the same level; (6) the *corymb*, where the flowers reach the same level, but where the pedicels do not spring from the same point (as in elder and hawthorn). Flowers and F.-buds spring from modified leaves named *bracts*, those of the secondary F.-stalks being termed *bractlets*. Where a circle of bracts surrounds a F.-head (as in daisy), the circle is named an *involucre*. The coloration of flowers, their physiology as concerned with fertilisation of the seed and with plant reproduction generally, and many other points, will be found treated of in other articles relating to botanical subjects.

Flowers, Artifi'cial. The art of imitating the floral beauties of nature with varied materials is extensively practised in France and Italy. The chief seat of the art is Paris, and its productions are noted for great artistic beauty. Fine cambric is mostly used for petals, and taffeta for leaves; but velvet, gauze, silk, and crape are also in requisition. Stamens are represented with slender wire or stiffened silk threads, and stems are formed of stout copper wire. Veins, folds, and the peculiar markings of leaves are imitated by means of 'goffering' implements. Dyes for tinting are specially prepared. Most manufactories employ females, and produce only a component part of a flower, the parts being collected and grouped together by those who possess an intimate acquaintance with the natural objects. A. F. are much used for head-wreaths, dress-trimmings, bouquets, and table decorations. Great Britain carries on a large and annually-expanding import trade in A. F., chiefly with France. The value of the imports has more than quadrupled in twenty years; those of the year 1874 were valued at £447,050. Wax-flower making, which is almost exclusively practised in Great Britain, is quite a distinct art from the foregoing. (See WAX FLOWERS.) Other materials of the most diverse nature are employed in different countries for fabricating A. F. Feathers are widely used; the Austrians and Swiss use straw, the Brazilians gaudy insects' wings, and fish-scales, and the natives of the Bahamas and Mauritius delicate sea shells.



Flue. See CHIMNEY.

Flu'ids (from Lat. *fluo*, 'I flow') are bodies which yield without resistance to any given pressure, however small, unless they be supported by pressures in other directions. They thus embrace what are usually termed liquids and gases, and differ in this particular of non-resistance from solids, which comprehend all other known forms of matter. F., however, as we have them in nature, do not completely fulfil this condition. The *perfect* ideal fluid is not known; for in all viscosity, or what is termed fluid-friction, exists, in virtue of which work must be done to alter the relative positions of the component particles. As this viscosity gets greater and greater, the liquid fluid approaches more nearly the condition of a plastic solid, so that in certain instances it is impossible to say whether a given specimen of matter is a solid or a liquid. See GAS, LIQUID, SOLIDS.

Fluke, the name given to various species of parasitic animals belonging to the order *Trematoda* of the class *Scolecida* (q. v.). The *Trematoda* are nearly allied to the *Tæniada*, or the more familiar tapeworms. The flukes are sometimes called *suctorial worms*, from the fact that (as implied by the name *Trematoda*) they have one or more sucker-like pores whereby they adhere to the tissues of their hosts. The flukes are found as parasites and in a mature state in birds, fishes, and other *Vertebrata*. A very familiar form is the *Distoma* or *Fasciola hepaticum* or common liver F., which inhabits the liver and biliary ducts of the sheep, and when present in numbers produces the disease in that animal known to veterinarians as 'Rot' (q. v.). In the common F. the characters of the *Trematoda* may be conveniently studied. In all the flukes, with a single exception, a digestive system is present, although no true perivisceral or body cavity is developed. The digestive system is usually of branching shape, and opens externally by a single aperture only, which therefore serves both as mouth and anus. This opening is situated within the front or anterior sucker. The *sexes* in flukes are united in one and the same individual, and a *water-vascular system* is developed. The common F. attains an average length of an inch or more, and has a body of an oval and flattened conformation. The hinder sucker is not perforated, and between the two suckers the *generative pore*, or opening of the reproductive organs, is placed. The water-vascular system itself opens externally by a small aperture. The nervous system exists in the form of a ring of nerve-matter surrounding the gullet. The flukes pass through a complicated development. The young flukes appear to pass into water and gain access to the bodies of such forms as fresh-water snails. In this situation they develop into peculiar bodies called *Cercariæ* and *Cercaria-cysts*, each of which consists of a head-extremity and a tail. In some cases the *Cercariæ* appear to produce other *Cercariæ* like themselves. These latter, after some further changes, escape into the water, and gain access to the bodies of sheep along with water used for drinking. The flukes are not common parasites in man, although occasionally they are found in the human liver and its large veins. *D. lanceolatum* is another familiar species; and an Egyptian one, *D. hæmatobium*, occurs more frequently in man, and is dangerous to human life. An allied genus is *Diplostomum*, which occurs in numbers in the eyes of perches and other fresh-water fishes.

Fluores'cence, an optical phenomenon observed in certain substances (solution of sulphate of quinine, tincture of turmeric, uranium glass, &c.), which emit a diffused blue or green light when placed in the path of dark actinic rays of high refrangibility. Professor Stokes explains it as due to the degradation of the highly refrangible actinic rays into luminous rays of less refrangibility. It suggests a method for investigating the absorption lines of the ultra-violet rays of the spectrum, and is further a beautiful example of dissipation of Energy (q. v.) without the performance of useful work.

Flu'orine is classed amongst the elementary substances (see ELEMENTS, CHEMICAL), but up to the present time it has not been isolated. Its existence is surmised from the analogies existing between its compounds and those of chlorine, bromine, and iodine. It is, therefore, ranked with these substances, and they are called collectively the *haloids*, or salt-producers. F. occurs most abundantly combined with the metal calcium, as fluoride of calcium or fluor spar, and from this substance all compounds of F. are obtained. The only one of these of any practical importance is hydrofluoric acid, a compound of hydrogen and F., employed to etch glass. To prepare it, powdered fluor spar is heated with sulphuric acid in a leaden retort, when the gaseous hydrofluoric acid is disengaged, and may be used in this state, or conducted into water contained in leaden vessels, in which it is abundantly soluble. The reaction may be represented thus—

$$CaF_2 + H_2SO_4 = 2HF + CaSO_4$$

Solution of hydrofluoric acid must be preserved in leaden or gutta-percha vessels, as it attacks all others. The atomic weight of F. is 17, and the symbol for its atom F.

Fluorotype, a photographic process published in 1844 by Mr. R. Hunt. Paper is sensitised by means of a solution of bromide of potassium and fluoride of sodium, and afterwards with nitrate of silver. In developing, protosulphate of iron and weak hydrochloric acid are used; and in fixing, hyposulphite of soda is had recourse to.

Flu'or Spar, or **Derbyshire Spar**, a mineral of frequent occurrence in Derbyshire and Saxony, crystallises in the monometric system, and is usually found in veins, often as a gangue of galena and other ores, in granite, gneiss, mica-slate, clay-slate, limestone, &c. It is the fluoride of calcium (CaF_2), is commonly greenish, violet blue, or topaz-yellow in colour, though also found colourless, rose, crimson, or brown. It is transparent or translucent, is brittle, and of degree 4 in hardness. It is used as a flux for reducing metallic ores, and when heated with sulphuric acid yields hydro-flouric acid.

Flush, a nautical term applied to a ship's deck when it stretches from the bows to the stern in a uniform level, instead of curving upwards fore and aft.

Flush'ing (Dutch, *Vliessingen*, Fr. *Flessingue*, the town on the 'vliess' or 'channel' of the Scheldt), a fortified seaport of the Netherlands, province of Zealand, on the island of Wal-

cheren, at the mouth of the Western Scheldt, 4 miles S. of Middelburg and 35 W. by S. of Bergen-op-Zoom by railway. It is one of the strongest maritime forts in the Netherlands, commanding the entrance to the Scheldt, and has two large harbours, a dry dock, good roads, dockyards, arsenals, magazines, &c. There is a considerable Indian trade, besides active fisheries, and numerous regular steam-lines. Opposite F. is the fort of Breskens. Pop. (1873) 8929. F. was the first town that declared against the Spaniards in 1572. It was pledged by the Prince of Orange to Queen Elizabeth in 1585, and remained with the English till 1616. At the beginning of the 19th c. it was taken by the French, and was stormed and captured by the English under Chatham in 1809.

Flus'træ, or **Sea-Mats**, a genus of *Polyzoa* (q. v.) or *Bryozoa* (q. v.). They are frequently cast ashore in great quantities on the English coasts, and present the appearance of masses of pale-brown seaweed. When microscopically examined, they are seen to consist of a colony of animal forms, each member of the colony or *polypide* being enclosed in a little cell. The cells exist on both sides of the structure, and their tough outer wall or *ectocyst* remains, after the delicate living parts of the organisms have disappeared. Each little member of the colony possesses a mouth, surrounded by retractile tentacles, a digestive system, and male and female generative organs. The colony springs from a single egg, and is produced by a process of continuous *gemmation* or *budding*. The tentacles of *Flustræ* are arranged in an *infundibulate* or funnel-shaped manner. Hence *Flustræ* are included among the Infundibulate *Polyzoa*, or *Gymnolæmata*.

Flute (Old Fr. *flaüte*, from *flaüter*, and that from Lat. *flatare*, 'to blow'), a wind instrument of ancient origin. It remained for a long time a very defective instrument, but recent improvements (especially those of Boehm) in the size and position of the holes, and in the fingering mechanism generally, have removed most of its imperfections. The natural scale of the concert F. is that of D major, and its compass is nearly three octaves. It is sometimes called a 'C' F. because its lowest note is C. The *piccolo*, or octave F., has nearly the same range as the concert F., but an octave higher. The sounds of the F. are produced by the vibration of the column of air in the tube, the length of that column being determined by the fingering. They are very nearly Simple Tones (q. v.), and therefore somewhat wanting in richness.

Flute, in classical architecture, is a vertical channel or hollow moulding on the shafts of columns. In a horizontal section of a fluted Doric column, the flutes, twenty in number, are segmental concaves, and sharply intersect each other. In Doric, also, the F. is not terminated before reaching the base and capital, as in the other orders. The Tuscan is the only column that is never fluted; the Ionic, Corinthian, and Composite have each twenty-four flutes. In Romanesque the F. was bent from the perpendicular into curved and twining forms. See CABLING.

Flute'work, a general name given to those stops in organs in which the sound is not produced or qualified by the vibrations of a metal tongue or *reed*.

Flux (Lat. *fluxus*, from *fluo*, 'I flow'), a substance easily fusible added to assist the fusion of refractory materials. Limestone, fluor spar, borax, nitre, sal-ammoniac, common salt, crude tartar, and glass are used as fluxes. *Black F.* is used in the reduction of metallic ores. It is formed of two parts of tartar to one of nitre, mixed in small quantities in a red-hot crucible. *White* or *refining F.* is composed of equal parts of the same ingredients.

Flux (Lat. *fluxus*, from *fluo*, 'I flow'), an extraordinary issue or evacuation, generally from a mucous membrane. Formerly the term was applied to a variety of diseases, such as diarrhœa, dysentery, cholera, bilious attacks, menorrhagia, &c., but it is now seldom used. Dysentery was long known as *bloody F.*

Flux'ions, the mathematical method invented by Newton which corresponds to our modern Calculus (q. v.). It is founded upon the kinematical considerations of the motion of a point, a manner of procedure fundamentally identical with that of *limits*, which is now generally recognised as the only true logical method of establishing the first principles of the differential and integral calculus. The *fluxion* of x was written $\dot{x}$, and corresponds to $\frac{dx}{dt}$, the differential coefficient of x with respect to time; $\ddot{x}$ corresponds to $\frac{d^2x}{dt^2}$, and so on. The notation, though now superseded in investigations in pure mathematics, is yet very convenient in many physical problems, where time is the only independent variable. $\dot{x}$ was the *fluxion* of x, and x was the *fluent* of $\dot{x}$; and the integral $\int z\,dx$ was written by Newton $\boxed{z\,\dot{x}}$ and called the fluent of z.

Fly, a name given popularly to many insects, but zoologically restricted to members of the order *Diptera* (q. v.), or flies in which only two wings—the front pair—are developed, whilst the metamorphosis is perfect, and the mouth suctorial.

Fly'catcher, the name given to a large family (*Muscicapidæ*) of Insessorial birds belonging to the section *Dentirostres*, and also to various typical species of the family. The characters of the family are found in the bill being curved above and compressed at the tip. The tail and toes are long, and the tarsi short. The flycatchers are usually of small size, and their colours sober but pleasing. The familiar flycatchers of Britain are the pied F. (*Muscicapa atricapilla*) and the spotted F. (*M. grisola*). The former is found mostly in the N.W. of England, and appears to visit Norway and Sweden in summer. The colour of the female is a delicate brown above, and greyish beneath; the male being coloured dark brown above, the forehead having a white patch; while the tail is black, and the under parts white. The average length is 5 inches. The spotted F. arrives in England in May. It has been seen in S. Europe and S. Africa. Its general colour is a light brown above, the breast being white, and the sides yellowish brown. Its song is very feeble. The nest is ingeniously constructed of long hairs, grasses, mosses, &c.; and the eggs, numbering five, are bluish-white spotted with red. Exotic species are the paradise F. (*Tchitrea paradisea*) of India, and the fork-tailed F. (*Melvulus tyrannus*) of tropical America.

Fly'ing is the motion through the air of birds, insects, and bats. It does not include the leaping of fish, reptiles, and small quadrupeds, which is frequently assisted by membranes or fins acting as parachutes. As compared with walking and swimming, F. obviously is accompanied by the minimum of resistance from the atmosphere, and the maximum of displacement. The travelling surfaces or wings have therefore to be greatly increased; they act like twisted inclined planes. When the wing ascends and descends, it rotates within the *facettes* or depressions situated on the scapula and coracoid bones. The curves described by the wing and body in F. form waved lines intersecting at each beat of the wings. Professor Bell Pettigrew maintains that walking, swimming, and F. all take place in figure-of-8 curves; that wings (consisting of arm, forearm, and hand) are really screws, and reverse their planes at every stroke; and that they act not merely as elevators, but as buoys after the manner of kites. His experiments have been continued by Marey, Seneccal, Ciotti, and others. The muscles being arranged in a certain cycle, the shortening of the flexor halves and the lengthening of the extensor halves diminish the angles formed by the lever bones, and by the opposite muscular actions these angles are increased, and this alternation makes F. The power of F. varies with the size of wing, the dragon-fly and the albatross being conspicuous examples. The weight of the bird is indispensable to flight, the body by its fall elevating the wings, which are opposed obliquely to the air. A good deal of exaggeration occurs in the descriptions of the air-sacs and hollow bones found in some flying animals. The fifteen air-sacs described by Sappey are more probably connected with respiration; they do not occur at all in the bat. The rapidity of vibration in wings has also been exaggerated; it has been said that the blow-fly vibrates its wings 300 times per second. The actual velocity of the wing is probably greater in the case of insects, as it arises from the thoracic muscle, while birds have muscles distributed upon the pinion. The *libellulæ* of the dragon-fly, however, enter the root of the wing. The buzzing, whirring, and whistling noises produced by wings have some relation to the rapidity of stroke. In the case of birds which skim, sail, or glide, the pinion is greatly elongated and ribbon-shaped, but generally there is a relation between the weight of the animal, the area of its wings, and the rate of oscillations.

Most flying animals seem to have much more wing than they absolutely require, as considerable portions have been detached without seriously affecting F. It is maintained by De Lacy that the larger the animal the smaller relatively are its flying surfaces. The pigeon weighs eight times less than the stork, and has twice as much surface. A singular mode of F. is that practised by the large-winged oceanic birds, who begin by beating the water with the tips of their wings so as to force the body up. An account of the manner in which the feathers are arranged to make the wing impervious to air in the down stroke, and to increase or diminish its area, is given in Pettigrew's *Animal Locomotion*, p. 180. By the flexing of the wing in flight, the *remiges* or 'rowing feathers' are opened up, and the air permitted to escape. The wing is elevated by the muscle *pectoralis minor*, and depressed by the *pectoralis major*. Professor Pettigrew is of opinion that the effective stroke is given downwards and forwards, but the weight of observation seems to be against this view. For an account of the attempts made at artificial flight by means of gas, see BALLOON. Attempts have also been made to fly, not by a machine specifically lighter than air, but by the use of rigid inclined planes driven forward in a straight line, or revolving planes (aërial screws), and also by the vertical flapping of wings. The *aërostat* of Henson and Stringfellow was invented in 1843. Its vanes or paddles were driven by a small steam-engine one-third of a horse power. It had huge fixed bamboo frames covered with canvas, and a rudder also made of canvas, but movable within limits. Its weight was 12 lbs. (including superimposed planes of canvas, or aëroplanes, added by Wenham in 1867), and its sustaining area 36 feet. This machine was started by being run rapidly down hill, the sails being set at a small angle to the ground. Sir George Cayley's *aërial screw* consisted of two corks, in which wing feathers were stuck. The corks were connected by a shaft, and a thread wound on to a bow of whalebone caused the corks to rotate in opposite directions. In 1842 Mr. Phillipps made a small metal steam-engine with fans (weighing 2 lbs.), which flew across several fields. In 1863 the Frenchmen Nadar and De la Landelle completed several clockwork models (*orthoptères*), but their chief success was in the *helicopteric*, in which the steam-driven screws were arranged in tiers upon two masts. As regards artificial wings, the earliest (not reckoning mere parachute falls) seem to be those constructed by Borelli (*De Motu Animalium*, Prop. 196, 1680). The wings consisted of a rigid rod in front, and flexible feathers behind. He conceived that the air's pressure drove the bird forward like a wedge in the direction of its base. It is generally admitted that the horizontal impulse depends on the yielding or *elevation* of the free extremities of the quills in the downward stroke. Marey further says that the converse takes place in the up stroke, the posterior margin of the wing in both cases making an angle of 30° with the horizon (*Méchanisme du Vol chez les Insectes*, 1869). The wings constructed by Marey and Straus-Durckheim do not seem to differ in principle from Borelli's. Pettigrew's wave wing, on the other hand, closely resembles the actual construction of a bird wing. It has no rigid margin, is twisted on itself, and tapers from the root to the tip. Elastic reeds or fine steel rods are covered with silk, india-rubber, linen, &c. The wing is valvular, so that during the up stroke the superimposed air passes through, and it is made to vibrate obliquely, not vertically. The experiments made seem to destroy Chalvier's theory that all the work of F. was done by the depressor muscles, the air forcing the wing upwards to its original position. See Bell-Pettigrew's *Animal Locomotion* (1873).

Flying Bridge, a ferryboat attached by a long chain or rope to a buoy anchored in the centre of a river. The position of the buoy depends upon the width of the river and the rapidity of the current, but when properly chosen, the action of the current combined with the resistance of the chain causes the boat to move across the river. By setting the boat obliquely to the current, by the help of the rudder, the action of the current is resolved into two forces—one tending to separate the boat from the chain, and the other to move it at right angles to the chain. The resistance of the chain to breaking counteracts the first of these, and the second only takes effect, the boat thus sweeping across the stream in an arc of a circle of which the buoy is the centre. Flying bridges are often used for military purposes.

Flying Drag'on or Liz'ard (*Draco volans*), a species of *Lacertilia*, or lizards, found in the E. Indies and Indian Archipelago, and so named from the possession of a *patagium* or wing-like membrane, enabling the animal to take flying leaps from tree to tree. The skin on each side of the body is extended and supported on six of the anterior ribs, which extend in a straight manner from the spine. This apparatus acts merely as a kind of parachute, and can in no sense be said to represent wings or organs of true *flight*. The colour of the F. D. is an olive brown, and the average length about 5 or 6 inches. An allied species is the fringed dragon, or *D. fimbriatus* of Sumatra. These lizards form the modern representatives of the great extinct reptiles known as *Pterodactyles* (q. v.).

Flying Dutch'man, The, like many other mediæval legends, is a growth by accretion rather than a single independent creation. It is traceable to the 16th c., and is typical of a time of rude religious feeling and of wild seafaring adventure. The germ of the story, in its varied forms, is akin to that of Odysseus and the Wandering Jew. For some great sin an accursed mariner is doomed to perpetual and aimless cruisings. In modern forms of the legend he is rescued from his fate by some holy interposition—a religious amulet or a faithful woman's love. According to a late version, the F. D. was an Amsterdam vessel, the master of which, Van der Decken, swore on a certain tempestuous night to make the Cape or to be 'eternally damned,' and 'though he should beat there till the day of judgment;' and there he is still to be seen, with crowded sail, tearing along in the wildest weather. Heine has made the legend the subject of a beautiful tale; Wagner weaves it into one of his finest operas, treating it as symbolical of the universal longing for rest from the storms of life.

Flying Fish, a name popularly given to all fishes which, from the large development of their pectoral fins, possess the power of leaping from the water and of supporting themselves for short distances in the air. The typical F. F. is the Teleostean species *Exocœtus volitans*, belonging to the family *Esocidæ*, or that of the pikes. In this fish, found in warm seas, the pectoral fins are elongated, as is also the lower lobe of the tail-fin. No teeth are borne on the palate. The swimming or Air Bladder (q. v.) is of very large size. The 'flight' of the F. F. is short and imperfect, and appears to result in greater part from the impetus which the fish gains in its primary rush through the water. Another species also known by the name F. F. is the Flying Gurnard (q. v.). The true F. F. swim in large shoals, and form the prey of other fishes. They are much esteemed on account of the delicacy of their flesh, and may be caught at night by exhibiting a torch or other light, this process seeming to attract them. The dolphin-fish, or *Coryphæna*, is the natural enemy of the F. F., and pursues them with great dexterity.

Flying Fox. See KALONG.

Flying Gur'nard (*Dactyloptera*), a species of *Triglidæ* or Gurnards (q. v.), so named from the large development of the pectoral or breast fins, by aid of which they are enabled to raise themselves from the water. The common F. G. is the *D. volitans* of naturalists, and is very common in the Mediterranean Sea. It attains a length of from 10 to 15 inches, and is of a brown colour above, variegated with bluish hues. The under parts are rose-coloured, and the fins are black and spotted with blue. An allied species is the *D. orientalis*, or Indian F. G. of the Indian Ocean, which is distinguished by the possession of two elongated filaments placed in front of the dorsal fin. Like the true flying fish, it is pursued by the dolphin-fish.

Flying Le'mur, or **Colu'go** (*Galeopithecus*), a peculiar genus of *Mammalia*, so named from the possession of an expansion of the skin along the sides of the body, uniting the fore and hind limbs, and also extending between the hind-limbs and tail. The possession of this membrane enables the animal to effect springing leaps from tree to tree, but does not confer upon it any power of true flight. The flying lemurs have been by some naturalists associated with the lemurs or lower *Quadrumana*, or monkeys, while other authorities have regarded them as forming a connecting link between the order *Insectivora* (moles, shrews, &c.) and that of the *Quadrumana*. The *G. volans* of the Eastern Archipelago is the most familiar species. The toes are free, and not united by or connected with the membrane. Each foot has five toes, but neither the great toes nor the thumbs can be opposed to the other digits, so as to convert the

feet into hand-like organs, as in many monkeys. The teeth resemble in many respects those of *Insectivora*. There are four upper and six lower incisors, and two canines, four præmolars, and six molars in each jaw. The six lower incisors are divided into narrow strips or portions, like the teeth of a comb. The flying lemurs average in length about $1\frac{1}{2}$ feet, are nocturnal in habits, and live chiefly on fruits, small birds, insects.

Flying Mouse. See FLYING PHALANGER.

Flying Phalan'ger or **Oposs'um** (*Petaurus*), a group of Marsupial (q. v.) mammals, allied to the kangaroos, &c., and included in the family *Phalangistidæ*, or that of the phalangers. The most familiar examples are the *P. sciureus*, or flying squirrel, the great F. P. or *P. Australis*, the Ariel P. or *P. Ariel*, and the *P. Taguanoïdes*, or Taguan. The opossum mouse, or flying mouse (*Acrobates pygmæus*), is also nearly allied. Like the Flying Lemur (q. v.), the F. P. has a fold of skin along each side of the body, uniting the fore and hind limbs. It is nocturnal in habits, and its *patagium* or fold of skin enables it to take flying leaps among the trees. The tail is not prehensile. The F. P. is confined in its distribution to Australia. The flying mouse attains a length of about $3\frac{1}{2}$ inches, while the other species vary in length from $1\frac{1}{2}$ to 2 feet. The prevailing colour is brown, and the fur is soft and glossy.

Flying Squid (*Ommastrephes*), a genus of *Cephalopoda* (q. v.), or cuttlefishes. These animals derive their popular name from their habit of leaping from the water, sometimes with force sufficient to land them on the deck of a ship. They belong to the Dibranchiate cuttles, and to the section *Decapoda* ('ten-armed'). They are included in the family *Teuthidæ*, or that of the Squids. The flying squids are most frequent in tropical seas, but are also found in temperate regions.

Flying Squirr'el, the name given to various genera of Rodent *Mammalia*, resembling the Flying Lemur (q. v.), and Flying Phalanger (q. v.), in that the body is provided with lateral expansions of the skin, forming a kind of parachute serving to sustain the animal in its flights from tree to tree. The flying squirrels occur in S. Asia, Polynesia, N.E. Europe, N. America, and Siberia. They belong to the genera *Pteromys* and *Sciuropterus*, and are included in the squirrel family (*Sciuridæ*). The Taguan F. S. (*Pteromys petaurista*) has no relationship with the phalangers. It inhabits India. The *Sciuropterus volucella*, or Assapan, is an example of the second genus, this form occurring in N. America, and attaining a length of 5 or 6 inches. The colour is brownish grey above, and white below. The fur is not of high value, but is frequently used along with that of other species of Squirrels (q. v.).

Fly-Pow'der is the name given to a compound of metallic arsenic and arsenious acid sold on the Continent for the purpose of killing flies. Such a dangerous compound should never be used for such a purpose. Flies and gnats are repelled by the odour of the oils of turpentine and rue, and quassia acts upon them as a poison.

Fly'trap. See DIONÆA.

Fly'wheel, in mechanism, a wheel fixed upon a revolving shaft and having a heavy rim, its use being to equalise the motion of the shaft, which without it would at some times rotate much faster than at others. Its theory can be most easily explained by reference to the F. of a steam-engine driving the machinery of a factory. Here, in ordinary cases, the resistance (due to the machinery) which has to be overcome by the engine changes continually throughout the day, but for any small interval of time (as that in which the engine makes one revolution) it is practically constant. The mean effort exerted by the engine in that period has been equal to the mean resistance to be overcome; but instead of being constant, it has varied continually, being at one instant smaller and at another greater than the resistance. *Of itself*, therefore, it could not drive the machinery continuously, but only by jerks. A heavy F. placed upon the shaft, however, entirely obviates this difficulty, and by its means any required degree of steadiness can be obtained. The engine expends energy, at starting, in accelerating the velocity of the mass forming the F., and this energy remains stored up in the wheel after it has attained the required velocity. When the resistance becomes greater than the effort, the deficiency is supplied from this storehouse of energy, the velocity being retarded in consequence; when the effort exceeds the resistance, the surplus is absorbed by the F. again with a corresponding acceleration. By making the F. heavy enough, the proportion borne by this surplus and deficiency to the whole energy stored up may be made as small as we please, and thus the fluctuations of speed may be made correspondingly small. In ordinary machinery the ratio borne by the difference between the maximum and minimum velocities to the mean velocity is about 30 : 1.

Any machine (as a punching machine, for instance) in which the resistance varies very greatly periodically should be fitted with a F. of its own besides the one on the engine. It may be mentioned that in certain cases flywheels, or their equivalent, are employed to store up energy in order that, by being brought suddenly to rest, they may be able to exert an enormous pressure through a very small distance, as in stamping a coin.

Foch'abers (Gael. *Faichaber*, 'the plain of the confluence;' anciently *Beul-ath*, 'the mouth of the ford'), a village of Elginshire, on the Spey, 9 miles E. of Elgin, and a station on the Inverness and Aberdeen Railway. F. is beautifully situated in a valley, and consists chiefly of a square and four main streets. The principal buildings are the Established, Free, and Episcopalian churches; and the Milne Free School, founded by A. Milne, a native of F., who died at New Orleans, U.S., and left 100,000 dollars for the purpose. Near F. is Gordon Castle, a seat of the Duke of Richmond. Pop. (1871) 1227.

Fo'cus (Lat. 'a fireplace'), in physics, is the point at which rays of light, heat, or sound meet after reflection or refraction. From certain important geometric properties of the conic sections with respect to certain points, the name was applied to these points, and has now undergone a much wider extension of signification in mathematics.

Fodd'er (Old Eng. *foder*, Dutch, *voeder*, Ger. *futter*), a name given to the food of cattle. The term is vaguely employed, but generally it is restricted to such plants and crops as are consumed in a green or fresh and succulent condition. F. is also an obsolete term for a weight of lead or other metal in England, the precise amount of which varied in different localities.

Law regarding F.—It is an implied obligation on a tenant of land that he shall cultivate it according to the rules of good husbandry, and these are commonly held to require the tenant to consume upon a farm the hay and straw produced by it. Local custom is, however, the rule of law in the matter; and it differs over England as regards a tenant's right to remove or sell hay and straw, the uniform rule, however, being that the manure afforded by the land must be returned to it. In Scotland the rule of good husbandry, and by consequence the law, is uniformly against the tenant having a right to sell or remove fodder. See LEASE.

Fœ'nus Naut'icum (Lat. 'interest on ships') is the rate of interest proportioned to the risk which a person lending money on a ship, on Bottomry Bond (q. v.), as it is called, is entitled to demand.

Fœ'tus (Lat. 'what is produced or bred,' from the obs. *feo*, 'I produce'), the term applied in medicine to the young of viviparous animals in the womb, and of oviparous animals in the egg, after its parts are distinctly formed, until its birth. Previous to the time of its complete formation it is called *embryo*. In the human subject the F. is developed at the end of about the fourth month of gestation; but there are certain points in which the F. at the full period differs anatomically from the child shortly after birth, and especially as regards the circulating apparatus. During pregnancy the *placenta* (popularly termed the after-birth) is developed on the inner wall of the uterus. This organ is chiefly composed of blood-vessels, and from it proceeds the umbilical cord, which conveys arterial blood to the F., and returns it to the placenta. The umbilical cord connects the placenta with the umbilicus or navel of the F., and is the channel by which the F. receives its nourishment from the maternal structures. The circulation of the blood in the F. differs from that in the child immediately after birth; for during fœtal life the circulation is carried on upon the mode of that of the higher reptiles, but afterwards, when certain changes have been accomplished, it becomes that of the complete warm-blooded animal. Up to the time of birth the partition between the auricles of the heart of the F. is incomplete, and the auricles communicate with each other by means of an aperture called the *foramen ovale*. There

is also a direct communication between the pulmonary artery and the aorta by the *ductus arteriosus*, and another direct channel between the umbilical vein and the *vena cava*, by the *ductus venosus*. The blood brought from the placenta by the umbilical vein is partly conveyed at once to the *vena cava ascendens* by means of the ductus venosus, and it partly flows through two trunks that unite with the portal vein, returning the blood from the intestines into the liver, thence to be returned to the vena cava by the hepatic vein. The blood that enters the vena cava is purely arterial in its character, but it loses this character in some degree by the time that it reaches the heart, from its being mixed in the vessels with the venous blood returned from the trunk and the lower extremities. The arterial current, on entering the right auricle, is directed by the Eustachian valve into the *left* side of the heart through the *foramen ovale*, whilst the venous current that is being returned by the descending cava is directed into the right ventricle. When the ventricles contract, the arterial blood contained in the left ventricle is driven into the ascending aorta, and supplies the head and upper extremities before undergoing further admixture. The venous blood contained in the right ventricle is driven into the pulmonary artery, and thence through the *ductus arteriosus* into the descending aorta, supplying the trunk and lower extremities with a mixed fluid. The head and upper extremities are thus supplied with blood nearly as pure as that which returns from the placenta, but the rest of the body receives a mixed fluid, from part of it having previously circulated through the system. The changes which occur in the organs of circulation and respiration at birth are more immediately determined by the inflation of the lungs with air during the first inspiration, by the dilatation of the pulmonary blood-vessels with an increased quantity of blood, and by the interruption to the passage of the blood through the placental circulation. These changes are speedily followed by shrinking and obliteration of the *ductus arteriosus*, and of the umbilical arteries, from the hypogastric trunk to the place of their issue from the body by the umbilical cord—by the cessation of the passage of the blood through the *foramen ovale*—by the closure of the foramen, the obliteration of the umbilical vein as far as its entrance into the liver, and of the *ductus venosus* within that organ. Blood ceases at once to pass through the *foramen ovale* from the moment of birth, or as soon as the left auricle becomes filled with blood returning from the lungs; but the actual closure of the foramen may not take place for a considerable time, and it sometimes happens that the foramen remains open, constituting the malformation attending the *morbus cœruleus*.

The average length of time which elapses between conception and parturition in the human female is 280 days or forty weeks. Gestation, however, may be prolonged for two or even three weeks beyond that period; and it has been ascertained from observation among the lower animals, that the prolongation of the period may depend on some peculiarity in the embryo derived from the male parent. A case came under the observation of the writer in which a female, suffering from acute mania, admitted into an asylum, gave birth to a child 296 days after her admission. The shortest period at which gestation may terminate, consistently with the life of the child, has not been definitely fixed, owing to the difficulty of ascertaining the exact length of gestation. There are, however, satisfactory cases on record in which, from the degree of development of the F. at birth, it might be certainly known not to have attained twenty-six or twenty-seven weeks, or little more than six months, and in which the infant was reared in health and vigour.

Law Regarding F.—In medico-legal inquiries it is frequently of great importance to ascertain the age of the F., and to facilitate such conclusions, the main points regarding the physical characters of the F. during the stage of development have been carefully noted and described by physiologists. In the F. of nine months the length is from 17 to 21 inches, and the average weight about 6½ lbs. The length and weight of the male infant slightly exceeds that of the female. No period has been fixed by law beyond which a child born in wedlock may be pronounced illegitimate, nor has the shortest limit been fixed within which a child may be born capable of being mature. In consequence of this indefiniteness many important cases have appeared in the law courts. The question as to what constitutes live birth is of much importance, some maintaining that muscular movement is indicative of life, and others that where respiration has not taken place the child was still-born. The latter view is that more generally adopted in this country, and the question as to respiration having taken place can be easily determined, for the lungs previously to the act of inspiration are dense and solid in structure, and their specific gravity being greater than that of water, they sink when immersed in that fluid, whereas lungs or portions of lungs that have respired float in water. See Quain's *Elements of Anatomy*, edited by Professors W. Sharpey, Allen Thomson, and E. A. Schäfer (Lond. 1876).

The destruction of an unborn infant, though an indictable offence, is not murder. See ABORTION; GESTATION, LAW REGARDING; BIRTH, CONCEALMENT OF; PREGNANCY, CONCEALMENT OF.

Fog (of Danish origin), or **Mist** (Old Eng. *mist*, 'darkness'), is produced by the condensation due to cooling of the aqueous vapour in the air into the form of minute drops of water. The direct cause of its presence may therefore be either the indraught of a cold current into a warm mass of air, or of a warm current into a cold mass of air. The rapid cooling of the ground in contact with air is also frequently attended with the appearance of F., as in the case of the evening mists. Morning mists are often vaporised and dispelled as the day advances by the heat of the sun.

Fogarasy, János, a Hungarian scholar and lawyer, was born at Käsmárk in 1801. He gained considerable reputation from his works on jurisprudence, filled several public offices, and in 1848 was made a member of the financial council of Pesth. F. has zealously studied the Magyar tongue, and made important contributions to philology. Among his writings are *A' Magyar nyelo' metaphysicdja* (1834), *A' Magyar nyelo szelleme* (1845), a Magyar-Latin dictionary (1835), and various legal and linguistic works. F. and another eminent Hungarian scholar, Czuczor, are the authors of the Dictionary of the Hungarian Academy.

Foggia, a town in the S. of Italy, in the province of the same name, 80 miles E.N.E. of Naples, on the river Cervara, and a station on the railway to Brindisi. It is the commercial centre of Apulia, and has great corn-stores, and a trade in cattle and wine. Pop. (1871) 34,181. F. is said to have been built from the remains of the old Arpi. The Emperor Friedrich II. held a parliament here in 1240. It was the scene of his wife's death in 1241, and of Manfred's victory over the Pope's troops in 1254. Towards the end of the 18th c. it was the seat of the court of Ferdinand I.

Fog-Signals, audible signals used on board ship, on the sea-coast, on railways, and elsewhere during fog or mist, when the ordinary visible signals cease to be of use. The signals commonly used at sea are the striking of a bell or gong, or the blowing of a horn or steam-whistle; the latter, where it can be used, being probably the most effective. Fog and mist very greatly interfere with the transmission of sound through the air, but further experiments are required in order that precise conclusions may be arrived at on this subject. Recent experiments (1874) by Dr. Tyndall have shown that an optically clear atmosphere is not always the best for transmitting sound, and that the report of a gun in certain circumstances is superior as a fog-signal to a horn or steam-whistle. Such signals as are mentioned above do no more than announce the presence, and approximately the position, of a vessel. In the navy a code of F.-S. is in use, by which the ships of a fleet can communicate in thick weather; there does not seem any reason to prevent the use in the merchant service of an alphabet 'of longs and shorts' (like the Morse alphabet), which would render communication, at present impossible, very easy. The F.-S. used on railways are small packets of detonating material, placed upon the rails and exploded by the wheels of the engine passing over them.

Föhr, an island belonging to Denmark, lies off the W. coast of Slesvig, in the North Sea. Area, 28 sq. miles; pop. 4500, mostly Frisians. It exports to Hamburg large quantities of oysters, cheese, and hosiery. Wyk, the chief town, is a bathing-place, and has had steamboat communication with Cuxhaven on the Elbe since 1833.

Foil, a sword-like weapon used in fencing, is a pliable, highly-tempered bar of steel, from 31 to 38 inches long. The blade is

edgeless, and is protected at the point by a 'button.' The F. is only used for thrusting.

Foil (Fr. *feuille*, Lat. *folium*, 'a leaf'), in the arts, plates of metal beaten or rolled out to a state of great tenuity. Tin-F. not exceeding $\frac{1}{1000}$th of an inch in thickness is much used for lining boxes and packages in order to exclude moisture, or to preserve the flavour and aroma of their contents. When covered with mercury it is also employed for silvering looking-glasses. Till 1840, tin amalgam was exclusively employed for that purpose, but the pernicious effects its preparation had upon the health of the workmen, has chiefly led to the adoption of other methods of silvering. F. of copper and its alloys has long been manufactured at Nürnberg and Fürth in Bavaria; hence it is sometimes called *German F.* The manufacture of bronze powders is simultaneously carried on there in order to utilise the F. waste. Highly-polished thin sheets of silvered copper constitutes jeweller's F., which is coated with transparent-coloured varnishes, and placed under precious or factitious gems to enhance their brilliancy and colour.

Foix (Lat. *Fuxum*), a small French town in the department of Ariège, 467 miles S. of Paris. It stands on the Ariège, is very irregularly built, and is overlooked by three towers, part of the old château of the Counts of F. The chief building is the Gothic church of St. Volusien. F. has ironworks and some trade in pitch. Pop. (1872) 5429.

Foix, Comtes de, an old French family which arose in the 11th c. Among its chief members are **Roger**, who received from his uncle, Comte de Carcassonne, the lands of F., now the department of Ariège, whence he took the title Comte de F. He died in 1064. His nephew, **Roger II.**, joined the first crusade, and died in 1125. Roger II.'s grandson, **Roger-Bernard I.**, received large additions to his estates from Raymond V. of Toulouse, and in 1185 obtained the marquisate of Provence from Alfonso II. of Aragon. His son **Raymond-Roger** was the ally of Raymond VI. of Toulouse in the Albigensian crusade, and after a determined resistance to Simon de Montfort, in which he proved himself a brave and skilful soldier, died in 1223. He was a patron of the Troubadours, and wrote several poems. **Roger-Bernard II., the Great**, was the sole ally of Raymond VII. of Toulouse against the forces of Northern France. He was twice excommunicated, and died in 1241. His grandson, **Roger-Bernard III.**, one of the best French poets of the 13th c., fought against the house of Armagnac, a feud maintained after his death in 1302 by his son **Gaston I.**, and ended in the time of his grandson, **Gaston II.**, who contributed greatly to the victory of the Navarrese over the Castilians at Tudela in 1335, did good service against the English in France, and died in 1343. He was succeeded by **Gaston III.**, who was born in 1331, and surnamed *Phœbus* from his beauty. He was made king's lieutenant in Gascony and Languedoc, married a daughter of the King of Navarre, served against the Slavic heathens of Prussia, rescued the royal princesses when they were shut up in Meaux during the Jacquerie, and died in 1391. He was famous for his chivalrous courage and devotion to the chase. He is said to have kept 1600 dogs, and wrote a work *Phébus des deduitz de la Chasse des Bestes sauvaiges et des Oyseaulx de Proye*, which remained popular with the great nobles and gentry long after the middle ages had expired. Froissart, who spent a considerable time in Gaston III.'s residence of Orthes, where he picked up many of the most interesting tales in his Chronicle, has given a careful but over-flattering portrait of this prince. On his death the F. estates passed to another branch of the family. **Gaston IV.** ably opposed the English in Guienne, received the seignory of Carcassonne and the counties of Rouissillon and of Cerdagne from Louis XI., and died in 1472. His grandson, **Gaston de F., Duc de Nemours**, was the most famous of the family. He was the son of Jean de F., Vicomte de Narbonne, and of Marie d'Orléans, sister of Louis XII.; was born in 1489; was made Duc de Nemours in 1505, and in 1511 commander of the French in Italy. He defeated the Swiss at Como and Milan by his brilliant strategy, routed the besiegers of Bologna, beat the Venetians near Brescia and took that city, and on April 11, 1512, gained the crowning victory of Ravenna over the Spaniards, but was killed through his rash daring, and his death rendered the success fruitless. He was surnamed the *Thunderbolt of Italy*, and is almost unsurpassed as an example of youthful military genius. On his death the estates of F. passed to the King of Navarre, and in the time of Henri IV. were united to the French crown.

Fok'shan, or **Fokchani**, a town of Rumania, on both banks of the Milkova, which partly separates Moldavia and Wallachia, 45 miles W.N.W. of Galacz. It is largest on the Moldavian side, and has a total pop. of 37,500. There is an active river trade, chiefly in corn, with Galacz, and in the vicinity is produced the best wine of Moldavia. The Turks, who were defeated at F. with great loss by the Greeks, 1st June 1821, set fire to the town in September 1822.

Folc'land, or **Folkland**, was the land belonging to the state, corresponding in the old English constitution to the Roman *ager publicus*, and opposed to *bocland* or hereditary estate. With the growth of the kingly power the people's land changed into the king's land, and, after the Norman conquest, the F. became the *terra regis*, the personal estate of the sovereign. When the hereditary nature of the English monarchy was established, any private estates which might belong to the several rulers were fused with the F., which from William I. to William III. was viewed as the king's personal property. Now, however, it is placed at the disposal of Parliament, to be used in the people's service in the same manner as the other state revenues. See Freeman's *Growth of the English Constitution*, chap. iii. (Lond. 1872)

Földvar (Magyar, 'land-fortress'), or **Földvar Duna**, a town of Hungary, on the right bank of the Danube, in the county of Tolna, 80 miles S. of Buda-Pesth. It is strongly and beautifully situated on a hill, is noted for its sturgeon-fishery, and has trade in wine, corn, and salt. Pop. 11,758.

Fo'ley, John Henry, R.A., a sculptor of rare force of genius and artistic accomplishment, born in Dublin, 24th May 1818, distinguished himself in the drawing and modelling schools of that city, and removing to London, entered the Royal Academy at the age of sixteen. He was elected Associate in 1849, and R.A. in 1855. He first exhibited in 1839, when his two models, 'Innocence' and 'Death of Abel,' attracted favourable notice. His 'Ino and Infant Bacchus' (1840), purchased by Lord Ellesmere, his 'Death of Lear' (1841), 'Lear and Cordelia' (1842), 'Venus rescuing Æneas' (1843), bear witness to the industry with which he followed up his first success. He afterwards produced 'Prospero and Miranda,' 'The Mourner,' 'Egeria,' &c. His fame, however, most securely rests on his fine marble statue of 'Hampden' in Westminster Palace, his 'Lord Hardinge,' now at Calcutta, and the magnificent equestrian statue of 'Sir James Outram'—a work inspired with vigour and heroic feeling, and the artist's masterpiece. Like the 'Hardinge,' the 'Outram' is now in Calcutta. F. died in London, 27th August 1874.

Folia'tion, in geology, is, according to Sedgwick, a 'separation into crystalline layers of different mineral composition,' differing thus from cleavage, which is merely a disposition to *split* without mineralogical changes. Darwin gives many fine examples in his *Geology of South America*, and suggests that F. and cleavage are really parts of the same process.

Folign'o, a town in the province of Perugia, Central Italy, on the Torpino, 15 miles S.E. of Perugia by railway. It has a fine cathedral, a Palazzo Communale, a theatre, promenades, &c. The 'Madonna di F.' by Raphael is now in the Vatican. The chief manufactures at F. are parchment, wax-candles, and playing-cards. Pop. 7890. F. is the Umbrian Fulginii and the Fulignum of the middle ages. It was partly destroyed by an earthquake in 1832.

Folkes, Martin, an English antiquary, was born in London, 29th October 1690, studied at Cambridge, was elected Fellow of the Royal Society in 1714, and in 1741 became its president. He was afterwards president of the Antiquarian Society, and a member of the Academy of Sciences at Paris. Oxford honoured him with the degree of D.C.L., and his own university with that of LL.D. He died 28th June 1754. F. contributed many dissertations to the *Transactions* of the Royal and Antiquarian Societies. One of these, *A Table of English*

Gold Coins, was reprinted in 1745 with additions, and a new edition appeared in 1763 under the title of *A Table of English Silver and Gold Coins, new reprinted with Explanation* (2 vols.).

Folkes'tone (Lat. *Lapis Populi*, 'the stone or fortress of the people'), a thriving seaport and bathing-place in the S.E. of Kent, lies in a hollow at the base of high cliffs, 5 miles W.S.W. of Dover, and 83 E.S.E. of London by railway. It has a good harbour and a pier, from which a view may be had of the French coast, and coastwise from Dover to Hastings. There is a considerable trade and regular steam communication with Boulogne, distant about 30 miles. In 1875 there entered the harbour 1166 vessels, of 183,103 tons, and cleared 844, of 141,953 tons. Pop. (1871) 12,698. F. returns one member to Parliament along with Hythe.

Folk'-Lore (Ger. *Volks-Lehre*), a term borrowed from the German to describe that floating mass of legendary narrative, song, and saying which takes its rise during the early life of a nation, and exists solely in the memory of the people, unless at a later date its remains be gathered up and preserved in literary form. F.-L. in its wide sense belongs to anthropology and antiquarianism as much as to literature, since religious myths, ethnic peculiarities, physical conditions, mental characteristics, and social customs all come within its scope. The term is, however, generally restricted to the literature originating in that period of national history which the Germans call *sagenzeit*, or tradition-time, a period through which all peoples pass. In regard to these early sagas, it must be noted that they are not, even in their most fantastic dress, deliberate fictions, but are believed by teller and hearers; and that they grow insensibly by a very natural process of accretion, until what has been a legend or a ballad may result in a complete cycle of connected traditions. There is a further tendency in many cases to group a set of tales and poems round the centre figure, such as Beowulf was to the Low German, Karl the Great to the Frank, Arthur to the Briton, Fingal to the Gael, the Cid to the Spaniard, or Hiawatha to the American Indian. F.-L. is seen at its perfection in Hesiod and Homer, in the poetical traditions of the Greeks, 'the abundance, the beauty, and the long continuance' of whose early literature Mr. Grote pronounces a 'phenomenon which has no parallel elsewhere.' The F.-L. of Rome, if less rich and splendid, is even more eminently national than that of Greece; her early history is but a collection of F.-L. recast by subsequent historians. Modern Italy has produced another legendary growth of a different character, exhibited in the collection of Mr. Busk (*Roman F.-L.*, Longmans, 1874). The literary history of Oriental nations is marked by a F.-L. equally abundant, of which the Arabian or Arabico-Egyptian *Thousand and One Nights*, the Persian *Sindibad Nameh*, the *Pantschatantra*, and the Hindu Vedistic and Brahmanical legends present distinctive phases, while the Slavic races have also their stock of popular traditions. (See Eichhoff's *History of Slavic Literature*, Paris, 1839; Ralston's *Russian F.-L.*, Lond. 1873). Among the Gothic peoples of early Europe, however, their F.-L., which flourished with great luxuriance, exercised an influence on the formation of national character not equalled in the case of any other people. Tacitus mentions the 'old songs' of the Germans, and Jacob Grimm (in his *Deutsche Mythologie*) has thoroughly investigated the growth of these ancient traditions, which comprise, among many others, the *Niebelungen Lied*, the *Volsunga Saga*, the *Eddas*, and the *Lay of Beowulf*. (See also Müller's *Saga Bibliothek*, Mallet's Introduction to the *History of Denmark*, Dahlmann's *Historische Forschungen*, Murray's *Manual of Mythology*, Baring-Gould's *Myths of the Middle Ages*.) The Welsh *Mabinogion* is a collection of Celtic F.-L. As specimens of French F.-L. may be mentioned the *Amadis de Gaul*, the *Chronique de St. Denis*, *Chronique de Turpin*, *Roman de Garin le Loherain*, and the *Chansons de Geste* (Fauriel's *Origine de l'Epopée Chevaleresque*, Paris's *Romans des Douze Paris de France*). In this country the antiquarian side of F.-L. has been treated of by such writers as Browne (*Antiquitates Vulgares*), Brand (*Observations on Popular Antiquities*), Hone in his *Every-Day Book*, Chambers in his *Book of Days*, and Swanson in his *Handbook of Weather F.-L.* English F.-L., in its purely literary aspect, is of great antiquity and interest. Geoffrey of Monmouth's *Chronicle* is apparently constructed of F.-L.; while *King Horn*, the *Romance of Alexander*, *Guy of Warwick*, *Bevis of Hampton*, *Havelok the Dane*, the *Proverbs of Hendying*, the *Robin Hood Ballads* (Wynken de Worde's collection), and *Chevy Chase*, are well-known instances of English popular traditions and ballads. See Percy's *Reliques*, Campbell's *Tales of the W. Highlands*, Warton's *History of English Poetry*, Scott's *Border Minstrelsy*, &c.

Folk'mot (Old Eng. *folc-gemot*, 'meeting of the folk or people'), the name given in early English times to the popular assembly of the shire, which was composed of representatives from hundreds and townships. The scirgerefa or sheriff presided over the F., by which he was at one period probably elected, though not within historical knowledge. The F., according to Edgar's law, was held twice in the year, but it assembled in arms on any occasion of emergency. It is incorrect to suppose, as Mr. Kemble does, that this was the origin of the Witenagemote, since the F. exercised no legislative authority, but only judicial functions, and the Witan was at no time a representative body. See Stubbs's *Constitutional History*, vol. i., Freeman's *Norman Conquest*, vol. i. (1870).

Folk'right, an old English law term denoting the rights of the people by common law.

Fomenta'tion (Lat. *fomentatio*, from *foveo*, 'I keep warm'), an application of warmth and moisture to a diseased or painful part. This may be done by means of a cloth moistened with water and covered with gutta-percha cloth, to prevent evaporation; or by cloths wrung out of hot water, and frequently renewed. The water may be medicated with vegetable infusions, and in this manner opium, belladonna, camomile, turpentine, &c., are used as topical applications.

Fonblanque', Albany William, a journalist of high ability and character, was born in London in 1793. His father was an equity barrister of Huguenot descent, and F. was for a time a pupil of Chitty, the special pleader; but before he was twenty years of age took to journalism. From 1820 to 1830 he wrote for the *Times* and *Morning Chronicle*, while he contributed to the *Examiner*, the *London Magazine*, and the *Westminster Review*. From 1830 to 1847 he edited the *Examiner*, and showed a humour and a trenchancy of style which have been compared to those of Swift. F. was a singularly conscientious and honourable as well as an able writer. In 1847 he retired from the *Examiner*, on being appointed by Lord John Russell to the post of statistical secretary to the Board of Trade, but continued to write at intervals for journals and magazines. He died October 13, 1872. In 1837 a number of his articles from the *Examiner* were reprinted under the title *England under Seven Administrations*. See *Life and Labours of F.* (1874), edited by his nephew.

Fon'di, a decayed town in the province of Caserta, S. Italy, 50 miles S.E. of Rome, near the miasmic *Lacus Fundanus*, and on the Appian Way, which is here in a very perfect state. It is enclosed in part by cyclopean walls, and has a fine cathedral, while the vicinity still produces richly the *vinum Cæcubum* of classic times. Pop. 6478.

Fond du Lac (Fr. 'bottom,' *i.e.*, 'inner end of the lake'), the capital of a county of the same name, Wisconsin, U.S., on Lake Winnebago, at the mouth of F. du L. River, 148 miles N.N.W. of Chicago. It is the junction of three railways, and has regular steam communication with the ports on the lake. There are over twenty churches, two free libraries, an opera-house, public gardens, and four newspapers. Water is supplied by about 1000 artesian wells, and is noted for its mineral properties. Among the principal works are twelve steam saw-mills, six planing-mills, four flour-mills, three foundries, ten waggon and carriage factories, two paper-mills, and six cigar factories, besides large blast-furnaces and tanneries. Pop. (1870) 12,764.

Fonse'ca, Bay of, or **Gulf of Concagua**, a Central American inlet of the Pacific, between San Salvador on the N.W., Honduras on the W., and Nicaragua on the S.E. It is 50 miles long from S.E. to N.W.

Font (Lat. *fons*, *fontis*, 'a spring or well') is the name given to the receptacle for the water used in Christian baptism. As

this was performed in the early centuries by immersion, the F. was a large basin in the centre of the Baptistery (q. v.), generally about 6 feet across, and 3 or 4 deep, and below the level of the floor, like a tomb, with symbolical reference to the believer's being buried with Christ by baptism. The descent into it was generally by three steps, symbolical of the believer's renouncing the world, the flesh, and the devil; and the ascent by three, symbolical of his professing belief in the Trinity. The step on which the bishop stood celebrating the rite made up the sacred number, seven. When the innovation of baptism by aspersion was introduced in the Western Church, the F. took the form of a small vessel, such as is used at the present day. The *material* as a rule was stone, the basin marble. In *form* fonts were originally merely circular basins. In the 13th c., however, they were made octagonal, probably with reference to the eighth day of the child's life being the proper time for baptism, as it was for circumcision, between which and baptism the early Church held there was a strong analogy, the eighth being regarded as the first day of independent existence (*cf.* Gen. xvii. 12; Lev. xxii. 27). In the 14th c. and 15th c. they were richly sculptured. They were not at first raised on supports, but were afterwards supported on pillars, usually five, to represent our Lord and the four Evangelists. A F. at Hildesheim of the 13th c. rests on personifications of the rivers of Eden, for the four cardinal virtues; one at Salzburg, on four lions, and one at Liége, like the brazen sea of Solomon's temple, on twelve oxen. Latterly, too, the supports rested on a pedestal of three steps, for the same reason, as there were three steps in the old immersion F. As regards its *position*, as baptism is the rite of admission into the Church, the F. properly stood not far from the entrance of the church. Originally a F. was placed only in the bishop's church, which was therefore called 'the mother-church,' but latterly in all churches. See Walcott's *Sacred Archæology* (1868).

Font in Cathedral at Hildesheim.

Fon'tainebleau, a town and château in the department of Seine-et-Marne, France, 2 miles from the left bank of the Seine, and 35 miles S.S.E. of Paris. The town owes its origin to the château, which is one of the most magnificent buildings in France. As early as the time of Louis VII. it was a fine feudal structure, and it has been splendidly remodelled or extended by almost every succeeding king. It is a *mélange* of styles, and among its more interesting portions are the chapel of the Sainte Trinité, erected by François I., the gallery of frescoes of the 16th c., the gallery of Diana, restored by Napoleon I., the hall of council, decorated with pictures by Boucher, the ornate throne-room, and, grandest of all, the gallery of Henri II., containing a fine series of mythological pictures. The château, with its beautiful gardens, courts, and fountains, is surrounded by the grand old forest of F., which covers an area of 65 sq. miles. Of the historical events connected with the château, the more important are the execution of Monaldeschi in the Galerie des Cerfs by order of Christina of Sweden; the signing of the revocation of the Edict of Nantes by Louis XIV. in 1685; the celebration of Napoleon's marriage with Marie-Louise; and the imprisonment of Pope Pius VII. in 1816. The town has, among other good buildings, two large hospitals, one the gift of Madame de Montespan. There are large manufactures of porcelain and crockery, and an active trade in sandstone, grain, grapes (the famous *chasselas de F.*), and other fruits, horses and cattle. Pop. (1872) 10,941.

Fonta'na, the name of several Italian painters in the 16th and 17th centuries, of whom the most famous is **Domenico F.**, who was born at Mili, on Lake Lugano, in 1543. Trained to the profession of an architect at Rome, F. became the favourite of Cardinal Montalto; and when the latter succeeded to the popedom as Sixtus V., he was made papal architect, and as such completed the cupola of the basilica of St. Peter, placed on its piazza the obelisk which had been brought from Egypt in the reign of Caligula, designed the library of the Vatican, and restored the columns of Trajan and Antoninus. The successor of Sixtus V., Clement VIII., disgraced F., who took the post of architect to the King of Naples, and designed a royal palace and a harbour, which, however, he did not live to complete. F. died in 1607.—**Giovanni F.**, brother of the preceding (born 1540, died 1614), distinguished himself by his skill in hydraulic architecture.—**Carlo F.** (born 1634, died 1714) was also papal architect.

Fontanelles, membranous intervals or spaces found in the skulls of infants and of young animals, which the process of ossification has not reached. See SKULL.

Fontanes', Louis, Marquis de, known for his style of rhetoric and poetry as 'Racine's latest descendant,' belonged to an old Protestant family of Languedoc, and was born at Niort, 6th March 1757. He first became known in literature as the translator of Pope and Gray, and as the writer of two original poems, *Le Cri de mon Cœur* and *Le Verger*, both published in 1778. In politics F. was originally a royalist then a republican, although of a very moderate type, editing, during the Revolution, a journal entitled *Le Modérateur.* Compelled to take refuge in England after the 18th Fructidor, he there made the acquaintance of Chateaubriand. Returning to France after the 18th Brumaire, he became an ardent admirer of Napoleon, on whose fall he transferred his service to the Bourbons, and was raised to the peerage under Louis XVIII. His later years were devoted to an epic, *La Grèce délivrée.* His death took place 17th March 1821, in which year also a collection of his speeches was given to the public. A collection of his works both in prose and verse was edited by Sainte-Beuve in 1839.

Fon'tenay is the name of thirty-four places in France, of which the most important is **F.-le-Comte** (called during the Revolution *F.-le-Peuple*), a town in the department of Vendée, France, on the river Vendée, 25 miles S.E. of Napoléon Vendée. It has a fine Gothic church, with a crypt dating from the 11th c., a church of St. Jean, notable for the beauty of its spire, a Renaissance fountain, some manufactures of linen and coarse cloths, and a trade in timber, grain, hemp, wine, &c. Pop. (1873) 6129. F., which owes its origin to the château of the Comtes de Poitou, was ceded to the English, from whom it was taken by Du Guesclin after a heroic defence. It suffered ten sieges during the religious wars, and was dismantled under Louis XIII. The Vendéens gained one of their greatest victories here over the Republicans.

Fontenelle', Bernard Le Bovier de, a once famous French author, born at Rouen in 1657, was the son of a local procurator and of Martha, a sister of Pierre and Thomas Corneille. He began literary life at Paris under the auspices of his uncle. Here he made the friendship of St. Pierre, and soon joined in the great literary quarrel of Moderns *versus* Ancients, vehemently criticising the masterpieces of Greek art, held up as models by Racine and Boileau. Of Theocritus he said, 'Ses bergers sont trop bergers,' a phrase which has become classical. A few operas, his *Dialogues des Morts*, the *Entretiens sur la Pluralité des Mondes* (the speculative part of which is based on the Cartesian hypothesis of *vortices*), a translation of Van Dale's *History of Oracles*, in which and in his *Doutes sur le Système Physique des Causes Occasionelles* (of Malebranche) there is much covert scepticism, were the chief products of his pen down to 1688, when his *Poésies Pastorales* appeared. These were highly artificial in tone, and by no means justified his hard words against the great poets of antiquity. In 1697 he became secretary to the *Académie des Sciences*, of which he wrote a history; and during the next forty years he composed and pronounced

those *Éloges des Académiciens*, which are the real monument of his literary fame. The range of knowledge required for the task may be inferred from the fact that the list includes Vauban, Malebranche, Leibnitz, Newton, Boerhaave, &c. His judgments, generally just, are always expressed with marvellous clearness and grace. He died in his hundredth year at Paris, 9th January 1757, a living connection between the 17th and 18th centuries of French literature. F.'s *Œuvres Complètes* have been frequently published, the best edition being that of Paris (1818). See Troublet's *Mémoires sur la Vie et les Ouvrages de F.*, Charma's *Biographie de F.* (1846), and Flourens' *F., ou de la Philosophie Moderne relativement aux Sciences Physiques* (Par. 1847).

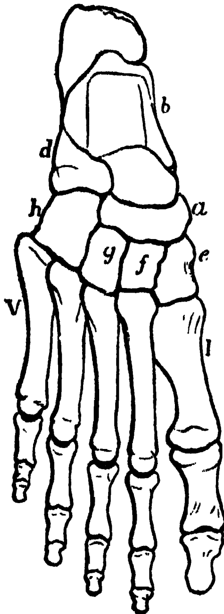
Fon'tenoy, or **Fontenoy-en-Puisaye**, a village (pop. 872) in the department of Yonne, Burgundy, France, 18 miles S.W. of Auxerre, has, among several places of the same or similar name in that department, the best claim to be considered the old *Fontanetum* or *Fontanidus in pago Altiodorensi*, where, on the 25th July 841, was fought the memorable battle between the sons of Hlodwig the Pious, which finally severed the connection between the Western and Eastern Franks, and from which we begin to date the separate existence of 'France' and 'Germany.'—F. is also the name of a village in the province of Hainault, Belgium, 4 miles S.E. of Tournay, where was fought 'the battle of F.,' a decisive contest in the war of Austrian succession, in which the French, under Marshal Saxe, defeated the English, Dutch, and Austrian allies, 11th May 1745. The forces were each some 60,000 strong, and the total loss amounted to about 7000 men.

Fonte'vrault (*Fons Ebraldi*), a small town in the department of Maine-et-Loire, France, 35 miles S.E. of Angers. It was formerly the seat of a celebrated abbey, the nucleus of the rich, influential order of F., founded by a Breton monk, Robert d'Arbissal, in 1099. The rule of the order was that of Benedict, but the monks were placed under abbesses, who were generally of illustrious family. In the 18th c. it had lost much of its wealth and power, but even at the time of the first French Revolution, when it was abolished, it held fifty-seven priories. The abbey is now occupied as a central prison. At F. are the tombs of the English Henry II., of his queen, Eleanor of Guienne, and of Richard I. Pop. (1872) 696.

Fontina'lis, a genus of *Musci* or mosses, distinguished by possessing the fructification within the leaves. The best-known species is the *F. antipyretica*, or greater water-moss, found growing on rocks and stones in the neighbourhood of water.

Food is whatever goes to the building up of the tissues and substance of a living being, and enables it to perform its necessary functions of life. All organisms, vegetable and animal, have their proper food which is essential to their existence. As a rule, vegetables build up, from the unorganised elements of the mineral kingdom, those compounds which serve for the nutrition of the animal kingdom. Animals, on the other hand, by feeding on the substances thus elaborated, decompose them, and return their constituents to the mineral kingdom; and thus the cycle of inter-dependent existence continues. Animals are classed according to their diet, as graminivorous or vegetable-eating, carnivorous or flesh-feeding, and omnivorous or eaters of both vegetable and animal F.; but primarily all animal F. is obtained from the vegetable world, carnivorous creatures only taking it at second-hand through the bodies of the animals on which they prey.

Human F. is frequently classified in a popular way under the two heads, F. and drink, which are regarded as functionally distinct, but such a subdivision is altogether fallacious, as there is no physiological or chemical ground to warrant the separation. Man is of all animals the most thoroughly omnivorous, drawing his F. from an endless variety of sources, and this he further varies indefinitely by cooking and compounding in every fashion that art can suggest. Notwithstanding this incalculable variety, the F. of man, as of every animal, is composed essentially of a limited number of alimentary principles. Analysis shows these principles to be—(1) Nitrogenous compounds, represented by casein in milk, and analogous substances found in cereals, peas, beans, &c., with a small proportion of albumen and other albuminates; (2) fat or butter; (3) a carbo-hydrate; (4) water; and (5) saline substances or ash, consisting of combinations of calcium, magnesium, sodium, &c., with chlorine, phosphoric acid, and other acid substances. Each of these five classes must be represented in every proper form of diet, and for the purpose of adequate nutrition they must be consumed in certain proportions, varying with conditions of climate and habits of life. The peculiar function of each has, however, not yet been definitely determined. The nitrogenous substances, the fats, and the carbo-hydrates become oxidised within the human body, and are thrown out as effete matter in the form of urea and carbonic acid. In becoming oxidised they give off within the human body the stores of energy which they contained, and that energy is manifested as vital heat, nerve and muscular action, &c. Water and saline substances, and the oxygen of the air inhaled by the lungs, are essential as oxidising agents. In addition to these principles there are, however, a variety of other substances taken into the human body, the functions of which obviously do not depend upon their being oxidised. They are various in their constitution, and are to be regarded as regulating the nutrition, or as having certain specific auxiliary or medicinal effects upon the essential ingredients of F. All kinds of F. thus come under one or other of the following heads, which are modified from a physiological and chemical classification of F. drawn up by Professors Huxley and Frankland:—Class I., Alimentary or necessary F., containing the five groups given above; and Class II., Medicinal or auxiliary F., subdivided into four groups, namely—(1) alcoholic substances, represented by beers, wines, and spirits; (2) spices and condiments, containing volatile oils, such as pepper, cinnamon, cloves, nutmegs, and mustard; (3) acid substances, such as apples, oranges, rhubarb, &c.; and (4) substances containing alkaloids or special active principles which act upon the nervous system as stimulants or sedatives, a most important group, embracing tea, coffee, and cocoa, with the various narcotics habitually indulged in by almost all races of mankind. See COOKERY, DIETETICS.



Fool. See COURT-FOOL.

Fools, Feast of (Lat. *Festum Stultorum*, *Festum Fatuorum*), was a festival instituted by the early Christian Church to take the place in the people's regards of the Roman Saturnalia (q. v.) or New Year festival. The great peculiarity of that festival, besides an unbounded extravagance of merriment, was that while it lasted all the ordinary conditions of society were reversed, slaves, *e.g.*, taking the place of their masters, arrayed in their clothes, and waited upon by them. And a similar inversion of the ordinary relations between the clergy and laity formed the principal feature in the F. of F. The festival extended from Christmas to the last Sunday of Epiphany, but the chief celebration was on Innocents' or New Year's Day. At first only the choristers took part in the ceremonies of the day, which consisted of the performance, with mock solemnity, of the ordinary religious rites, while the clergy formed the audience or part of it. But latterly all the servants of the Church, and even laymen, took part, and as time went on extraordinary license was introduced. A president being elected under the name of Pope of Fools, Archbishop of Dolts, Abbot of Unreason, Lord of Misrule, &c., the performers repaired to the church, where, dressed in the priests' vestments outside in, they read prayers from books turned upside down, with spectacles of orange-peel, and burned an old shoe or excrement in the censer; or, not sparing even the Church's most sacred rite of the Mass, ate sausages and puddings off the altar, or played at dice upon it. During and after the mock service, the church, which was thronged with a motley crowd of spectators, was a scene of the wildest riot and confusion, the maskers leaping and dancing like madmen, and singing obscene songs with obscene posturing, some of them being dressed up as dragons, hobby-horses, &c. Long before the Reformation the F. of F. had become such a scandal from the way in which everything sacred was turned to ridicule, that the clergy, who had themselves set the stone rolling, did everything in their power to put a stop to it; but all their attempts were unavailing, till the institution got its death-blow at the Reformation. See Du Tilliot's *Mémoire pour servir à l'Histoire de la Fête des Fous* (Laus. 1741, Par. 1751 and 1809).

Fool's Pars'ley (*Æthusa cynapium*), a species of poisonous *Umbelliferæ*, so named from its producing narcotic symptoms, and from its having been sometimes eaten in mistake for Parsley (q. v.). F. P. is a common British weed. It is distinguished

from other and allied *Umbelliferæ* by its flowers having deflexed *involucres* or circles of *bracts*. Probably, as is the case with *Œnanthe crocata*, or 'dead-tongue,' a near ally of F. P., the poisonous properties of the plant depend greatly on the locality and mode of growth.

Foot. This important part of the body is formed of (1) the tarsus, (2) the metatarsus, and (3) the phalanges. The *tarsus* is composed of seven bones, namely, the os calcis (*d*), astragalus (*b*), cuboid (*h*), scaphoid (*a*), and the three cuneiform, internal (*e*), middle (*f*), and external (*g*). The astragalus articulates with the lower end of the tibia and fibula. The *metatarsus* is formed of five bones (I. to V.), which are shafted bones, like those forming the metacarpus, or palm of the hand. The *phalanges* are attached to the extremities of the metatarsal bones, and are usually numbered, first (1), second (2), and third (3), from behind forwards. It will be observed that the great toe has only two phalanges. Structurally the F. is an arch supported on three piers, two in front and one behind. The posterior pier of the arch is formed by the heel, and the anterior piers by the balls of the great and of the little toes. The weight of the body is transmitted to this arch from the tibia to the astragalus. The F. is also slightly arched transversely. These characteristics of the F. of man adapt it to the support of the body in the erect position, and to biped progression. It wants the prehensile power seen in the F. of the anthropomorphic apes. On the whole the human F. is, in proportion to the size of the whole body, larger, broader, and stronger than that of any other mammal save the kangaroo. The plane of the F. is at right angles to that of the leg, its sole is concave, its great toe is usually unopposable, and the upper surface of the astragalus looks almost vertically upwards. All of these peculiarities distinguish the F. of man from that of the ape. The great toe, though in man one of the largest digits, is rudimentary or entirely absent in many mammals. In climbing animals it is considerably developed, and has prehensile characteristics, as in the gorilla and orang.

Bones of the Foot.

Foot, a measure of length, in almost universal use, and doubtless derived from the length of the human foot. The numbers expressing the length of the English foot in terms of the corresponding measures in other European countries and states are as follows:—Austria, ·964; Baden, 1·016; Bavaria, 1·044; France (Paris F.), ·938; Prussia and Denmark, ·971; Russia, 1; Saxony, 1·076; Würtemberg, 1·064. It is usually divided according to the duodecimal scale. An English mile contains 5280 feet.

Foot, in organ-building, is sometimes used to qualify the word *tone*, as '4-foot tone,' '8-foot tone,' &c. It here indicates the length of an open organ-pipe which would produce the required sound. Thus middle C is 2-foot tone, &c. The expression '4-foot,' '8-foot,' &c., applied to an organ-stop indicates the length of the lowest C pipe in that stop.

Foot-and-Mouth Disease (synonyms, *Eczema contagiosa* or *E. epizootica*, *Epizootica Aphtha*, and *Murrain*), a contagious disease of a febrile nature, chiefly affecting cattle and sheep, and characterised by the presence of a vesicular eruption in the mouth, between the toes, and around the coronets. The mouth or feet alone may be affected. In cows, the eruption may extend to the mammary gland, and necessarily affects the milk. Pigs, poultry, dogs, and more rarely man, are subject to F.; but horned cattle are the chief sufferers. The temperature first increases, and a vesicular eruption appears after an incubatory period of from three to four days. The animal exhibits great restlessness and uneasiness; saliva runs from the mouth, and a watery discharge from the eyes. The disease is one of a specific type caused by the presence of a specific poison. Pasture lands receive the contagious material or virus, and the disease thus spreads. One attack is not a protection against a subsequent attack, but the animal is usually attacked only once in a season. Microscopic examination of the discharges has as yet failed to detect any specific form of fungus or other parasitic organism which might be credited with causing the disorder. The febrile symptoms may cease in a week; but if the weather be unfavourable or the animals be exposed, a rough tracheal cough with expectoration may persist for a long time. The treatment consists in giving the animals plenty of cold water to drink, in which nitrate of potash (one ounce to a bucketful) may be dissolved. Soft food—mashes, &c.—should be given, and the sores on the feet should be dressed with a mild astringent solution—*e.g.*, by one ounce of carbolic acid lotion (made by adding one part of pure carbolic acid to sixteen of hot water) added to twelve ounces of white lotion or a solution of acetate of lead. Stimulants may be demanded in extreme cases of prostration, but bleeding and purging are carefully to be avoided. Sheep, as a rule, suffer most violently in the feet, and require more careful watching and treatment than cattle. An affected flock should be made to walk or wade once or twice daily through a shallow trough containing the solution of acetate of lead and carbolic acid above mentioned.

Foot'ball, a popular national sport, played during the winter months at all higher-class public schools and colleges. There are two distinct types of game played, and nearly every public school in England has its own peculiar modifications. Both make use of a ball and two goals, each of which consists of two upright posts with a cross-bar or tape at the height of about ten feet. The goals are placed at the extremities of the course, which has fixed boundaries. If the ball is sent beyond these boundaries it is for the time out of game, and must be returned according to rule. In the *Association* or Harrow game, the ball is round, and must not on any account be touched with the hand, except by the goal-keeper of each side. One goal is scored when the ball is sent through the posts beneath the tape, each side working the ball towards the adversary's goal. In the *Rugby* game the ball is oval; and any player, if *on-side*, is entitled to catch or pick up the moving ball, and run with it towards the adversary's goal. If stopped, however, he has to relinquish the ball, and put it *down* to ground, when a *scrimmage* takes place, each side striving to drive it through towards the other's goal. A goal is won when the ball is kicked *over* the cross-bar between the goal-posts or the goal-posts produced. International matches, between chosen teams of English and Scotch, are yearly played according to both Association and Rugby rules, and excite great interest in F. circles. For full information regarding the rules of the games, the clubs, and matches, see Alcock's *F. Annual.*

Foote, Andrew Hull, rear-admiral in the American navy, was born at New Haven, Connecticut, May 4, 1808. He entered the navy December 4, 1822, became a commander in 1852, and a captain in 1861. In February 1862 he received the command of the western flotilla, took Fort Henry, attacked Fort Donelson, where he was wounded, and on April 7 took Island No. 10. He received the thanks of Congress, and was made rear-admiral, June 16, 1862. F. was appointed to relieve Admiral Dupont at Charleston, but died at New York, June 26, 1863. Admiral F. was not only a gallant, chivalrous naval officer, but a man of singularly strong moral character.

Foote, Samuel, a famous English wit and dramatist, was born at Truro, Cornwall, in 1719, and entered at the Temple, but finding the law uncongenial, went on the stage, and made his *début* as Othello in 1744. He was a comic writer as well as an actor, and led a brilliant and dissipated life, until in 1766 he lost his leg by falling from his horse. This misfortune did not extinguish his mercurial gaiety. He appeared in parts which turned the want of his limb to stage account, and remained to the last recklessly improvident and irresistibly vivacious. He died at Dover, October 21, 1777. F. was an admirable mimic, and the cleverest manufacturer of *bon-mots* of his day, but many of his witticisms are vulgarly broad and personal, and would no longer be tolerated in society. Among his pieces are some of

the most amusing farces in the English language, but it is a sort of profanity to call him 'the modern Aristophanes.' A collection of his dramatic works appeared at London (4 vols. 1778; 2 vols. 1797). They were translated into German (4 vols. Berl. 1796–98). See Clarke's *Memoirs of Sam F.* (3 vols. Lond. 1805).

Foot-Guards. See GUARDS.

Foot-Pound is the work required to raise the weight of one pound through the distance of one foot at the surface of the earth; or it is the work which such a weight could perform in falling through the same distance in the same circumstances. The corresponding French unit of work is the *kilogrammètre*, which equals 7·233 foot-pounds.

Foot-Rot, a disease of sheep, characterised by the presence of cracks or fissures in the hoof, and by the subsequent appearance of ulcerated sores arising from the irritation consequent on the presence of dirt, sand, and other foreign particles. Occasionally the ulcerated action may proceed to a very great extent, the lesion being then termed 'foul-foot.' The milder forms of F.-R. appear to arise from unequal development or wearing of the hoof, consequent on the sheep being enclosed in soft meadow-lands where the hoof is subjected to the least amount of attrition. But in the more severe forms, F.-R. is probably connected with, and arises from, constitutional causes; and in the latter case, great attention to the general health is necessary, as well as the adoption of local treatment. The latter consists in the use of astringents and caustics where the ulceration is of any great extent. In mild cases, tar is a safe application, and butter of antimony, or a paste of flowers of sulphur and sulphate of copper in equal weight mixed with lard, is also to be recommended as useful in this complaint.

For'age (Low Lat. *foragium*, from the Goth. *fodur*, 'fodder'), the food of horses. In the army, field-officers, surgeons, and adjutants of infantry regiments receive an allowance in lieu of F. for every horse allowed by the regulations. The ration allowed for horses is 10 lbs. oats, 12 lbs. hay, and 8 lbs. straw in barracks; and 8 lbs. oats, 18 lbs. hay, and 6 lbs. straw in quarters. The troops in Great Britain and Ireland are supplied with F. under contract entered into by the commissariat department. The cost of F. and allowance in lieu of paillasse, according to the army estimates, was £612,000 for the year 1876–77.

Foraminif'era, an order of *Protozoa* (q. v.), or lowest animals, included in the class *Rhizopoda* (q. v.). The F. are distinguished by the possession of a shell or test of carbonate of lime, although the structure may occasionally be composed of sandy or *arenaceous* particles. Through holes or *foramina* in the shell the soft protoplasmic matter of their bodies can be protruded in the form of delicate interlacing filaments or *pseudopodia*. From the interlacing nature of these filaments, the name *Reticulosa* has been given to the F. by Dr. Carpenter, who describes the appearance of the pseudopodia as resembling 'an animated spider's web.' These filaments are used for grasping food-particles, and also subserve locomotion. In some cases (*e.g.*, *Miliola*) the pseudopodia are emitted, not through foramina, but by the mouth-opening or single aperture of the shell. The shells of F. have been divided into (*a*) the *porcellanous*, or those in which there are no foramina in the shell-wall; (*b*) the *arenaceous* shells, consisting of sandy particles; and (*c*) the *vitreous* or *hyaline* shells, which are glassy, transparent, and have their walls perforated. The shells of F. may be also divided into those consisting of a single chamber (*Monothalamia*), and those composed of many chambers (*Polythalamia*). The latter are originally single-chambered, and are produced by budding. If the budding of new segments proceeds in a straight line, a shell like that of *Nodosaria* is produced; whilst the spiral form of this process gives rise to a test like that of *Rotalina* or of *Discorbina*, &c. The shell-wall of F. appears to be perforated by a system of canals in addition to the foraminal apertures. The living matter of their bodies is of the simplest character, their protoplasm being destitute even of the nucleus and other structures found in most *Protozoa*. The F. are for the most part of microscopic size, and require the microscope for their investigation and recognition. Some extinct forms—notably the Nummulites (q. v.)—attained a larger size, the latter being found as large as a shilling, and frequently attaining even larger dimensions. The F. are found in the present day in waters of the sea, and in the bed of all our oceans, and most notably in those areas traversed by warm currents. Their shells form a thick layer of calcareous matter in the sea-bed. True chalk is a Foraminiferous deposit which was formed in this way in an ancient sea-bed. F. first appear as fossils in the Laurentian rocks where *Eozoon* (q. v.) is found. They occur in all the stratified formations up to the present day. Some species (*e.g.*, *Miliola* in Eocene rocks and *Nummulites* in the Middle Eocene) have attained a vast development in certain geological epochs.

Forbes', Duncan, of Culloden, one of the ablest and best men that Scotland has produced, was the second son of the proprietor of the estate of Culloden, and was born at Bunchrew —another estate belonging to the family—10th November 1685. His father, a stanch Presbyterian, had suffered much at the Restoration, and finally received a strange compensation in the privilege to distil whisky, under a merely nominal duty, on a third estate called Ferintosh, which privilege he used so extensively that to this day 'Ferintosh' in many parts of Scotland is synonymous with whisky. Duncan was sent to Edinburgh University when nineteen years of age, and lost his father the same year. Next year he was sent to Leyden, where he studied both law and Oriental languages. He returned home at the end of two years, passed as advocate in Edinburgh, was, through the influence of the Duke of Argyle (both a patron and a relation), appointed sheriff of Midlothian, and married Mary, a daughter of Mr. Rose of Kilravock. In 1715 he exerted himself to the utmost in suppressing the insurrection headed by the Earl of Mar; and when it was brought to a close, he showed the most active kindness in mitigating the fate of the unfortunate prisoners, who were treated with utmost rigour by the Government. He collected money for their defence, and publicly remonstrated with the Government on the cruelty they displayed. Some time after he proposed the plan, which Pitt sixty years later adopted with entire success, for the pacification of the Highlands, viz., restoring to the chiefs their forfeited estates, and employing the people in the service of the country. In 1716 F. was appointed depute to the Lord Advocate; in 1722 he was returned to Parliament for the Inverness burghs, and three years after was raised to the office of Lord Advocate. While in London, he was on intimate terms with Lords Mansfield, Lyttelton, and Hardwicke, as well as Sir R. Walpole, and was a valued member of the literary society in which Pope, Arbuthnot, and Swift held sway. In 1734, owing to the death of his elder brother, he succeeded to the family estate, and in 1737 was appointed President of the Court of Session. According to his best biographer, Dr. Hill Burton, he effected a thorough and most beneficial change in the proceedings of this court, having raised it to a state of efficiency which it has never surpassed. But it was in connection with the rebellion of the '45 that he rendered the most important services to the state. The members of the Government were singularly destitute of all resource, and for a length of time anything that was done in Scotland to save the country was mainly the work of Forbes. He kept the more reasonable of the Jacobites from rising, especially the great MacDonald and MacLeod clans in Skye and the islands, who themselves could have brought 8000 men into the field; and having restrained these, he may be said in a certain sense to have saved the Hanoverian throne. He gave not merely his great influence to this work, but he expended on it all the money he could raise, straining his credit to the utmost, yet the Government refused to repay him any portion of what he thus expended; and he died 10th December 1747, pressed by creditors whose claims he was unable to meet. Bishop Warburton calls him 'one of the greatest men that ever Scotland bred, as a judge, a patriot, and a Christian.' See Hill Burton's *Life of Duncan F.* (Edinb. 1848).

Forbes, Edward, a British naturalist, was born at Douglas, in the Isle of Man, February 12, 1815. At an early age he showed a bent towards the natural sciences, and when only seven had made a small collection of zoological and botanical specimens. In 1831 he entered Edinburgh University as a medical student. Here he studied till 1839, ultimately concentrating his whole attention on botany, zoology, and geology, to the exclusion of medicine, adding meanwhile to his stores of knowledge by excursions to Norway, the Alps, Austria, Algeria, and Southern Europe. In 1834 he became a member of the British Association, and in 1836 was one of the founders of the Edinburgh

Botanical Society, to both of which he contributed many valuable papers and reports. In 1841 he accompanied the *Beacon* in its surveying expedition to Asia Minor as naturalist, and from numerous dredging operations showed that the laws of geographical distribution in the depths of the sea were similar, and depended upon conditions similar, to those which held on land. On his return in 1842, he found that he had been elected Professor of Botany at King's College, London. In 1844 he became curator of the museum of the Geological Society, and palæontologist to the Ordnance Survey. In 1853 he was President of the Geological Society, and in May 1854 succeeded Professor Jamieson in the natural history chair at Edinburgh. This position he filled with great ability for only one short summer course, since his death occurred on 18th November of the same year. The peculiar merit of F. lay in his wide grasp of the whole range of the natural sciences, no one department being his peculiar study to the relative exclusion of the others. To a quick perceptive faculty of observation, and a retentive memory, he added a rare power of abstraction and generalisation, which is perhaps best displayed in his beautiful theory of the derivation of the present flora of the British Islands. His chief works are a *History of British Starfishes* (1841), *Travels in Lycia, Milyas, and Cibyratis* (1846), and, with Mr. Hanley, a *History of British Mollusca* (1850–53); but his great services to science can only be estimated from a consideration of his numerous memoirs on the classification of medusæ, mollusca, &c., on geographical distribution, and on subjects connected with every phase of natural science, all of which teem with novel and accurate information of varied description. He also drew up the valuable maps on distribution in Keith Johnstone's *Physical Atlas*. See *Memoir of Edward F.* (Camb. 1861) by G. Wilson and A. Geikie.

Forbes, James David, was born at Edinburgh, April 20, 1809, and passed most of his early life at his father's residence at Colinton, where he received private tuition along with his brother Charles. From 1825 to 1830, with the break of one year, he studied for law at Edinburgh University, devoting every spare moment, however, to astronomy, meteorology, and the physical sciences. In 1833 he threw up all legal pursuits, and was elected the successor of Sir John Leslie in the chair of natural philosophy at Edinburgh, a position which he resigned on account of failing health in April 1860, four months after he had become Principal of the United College in the University of St. Andrews. He died at Clifton, December 31, 1868. F. was a member of numerous scientific societies at home and abroad, and received the Royal and Rumford medals from the Royal Society of London, and two Keith medals from the Royal Society of Edinburgh for his contributions to science. The most important of these are the discovery in 1836 of the polarisation of heat by refraction and reflection, the subsequent investigations in its refrangibility and depolarisation, the observation in 1846 of the conditions of temperature at different depths in the soil, and experimental inquiry into the laws of thermal conduction in metal bars in 1861 and 1865, besides numerous valuable papers on climate, meteorology, and geology. His most famous work, however, is in connection with the motion of glaciers. The results of his investigations (see GLACIERS) are given in his *Travels through the Alps* (1843), *Norway and its Glaciers* (1853), *Tour of Mont Blanc and Monte Rosa* (1855), and *Occasional Papers on the Theory of Glaciers* (1859). These works display at once his high faculty as an observer of natural phenomena, his rare skill as an experimentalist, and his literary power as a graceful and lucid writer. His *Life and Letters*, the joint production of Principal Shairp of St. Andrews, of Professor Tait of Edinburgh, and of Mr. Adams-Reilly, the Alpine traveller, was published by Macmillan & Co., London, 1873.

Forbes, Sir John, a very able and successful physician, was born October 18, 1787, at Cuttlebrae, Banffshire. Educated at the universities of Aberdeen and Edinburgh, he was first a naval surgeon, but leaving the service in 1816, graduated at Edinburgh, and practised as a physician there, in Chichester, and finally in London, where he rose so much in favour with society that he was knighted and became Physician in Ordinary to the Queen in 1853. His death took place at Whitechurch, Oxfordshire, November 13, 1861. F., besides being a very successful practitioner of medicine, was a zealous man of science. He may be said to have introduced the stethoscope into this country, was one of the editors of the *Cyclopædia of Practical Medicine* (1835), translated the works of Auenbrugger and Laënnec on auscultation, helped to found the British Medical Association, and started the *British and Foreign Medical Review*, editing it for twelve years. Among the other works of F., who during his latter years was one of the most distinguished and popular members of his profession, may be mentioned his *Physician's Holiday* (1849), and *Nature and Art in the Cure of Diseases* (1857).

Forbes, Sir William, Bart., of Pitsligo, was born at Edinburgh, 5th April 1739, became a partner in the bank of Messrs. J. Coutts & Co. in 1761, and in 1773 rose to be head of the eminent firm of F. Hunter & Co., eventually converted into the Union Bank of Scotland in 1830. He purchased the estate of Pitsligo, forfeited by Lord Forbes during the rebellion of '45, and erected the village of New Pitsligo. Often in London, he was one of the earliest members of the Literary Club, along with Johnson, Burke, Reynolds, &c. He wrote a life of his friend Dr. Beattie, printed with a 4to edition of his works in 1805, and the *Memoirs of a Banking House*, published in 1860. His nobility and rectitude of character are happily delineated in one of the introductions to *Marmion*. He died 12th November 1806.

Forbes Macken'zie Act. This is the title of a very stringent 'Act for the better regulation of public-houses in Scotland.' It is so named after the author of the measure. It continues the classification of spirit-dealers, as under former statutes, into (1) inn or hotel keepers, (2) public-house keepers, and (3) grocers and provision dealers. The sale of spirits in the first class is only permitted between eight o'clock in the morning and eleven o'clock at night during week days, except to *bona fide* travellers and lodgers. On Sunday the sale is prohibited except to lodgers and *bona fide* travellers. The same regulations apply to the second class, without any exception in favour of lodgers or travellers. No certificate is allowed to be granted to any grocer or provision dealer for the sale of excisable liquors to be 'drunk on the premises,' if in these premises a sale is carried on of provisions to be consumed elsewhere. This latter class is also prohibited from keeping their premises open on Sunday, and from any sale of liquor between eleven at night and six in the morning. These are the leading provisions of this Act, which has given rise to so mnch vehement controversy N. of the Tweed. The supporters of the Act have cited voluminous statistics, which they contend prove that the Act has diminished drunkenness in Scotland. Its opponents, again, by a different manipulation of the figures, maintain that these statistics show a contrary result, and that even if they do show an apparent diminution in Sunday-drinking, the fact proves nothing; because to diminish public drinking on Sunday is only to increase drinking in private and in illicit houses. And public drinking, they maintain, is the smaller evil of the two; because it is better, they hold, that people should drink where the law can take cognisance of them than in places where it cannot. A bewildered public is thus almost led to acquiesce in Sydney Smith's celebrated dictum, that, except facts, there is nothing so misleading as figures. A Royal Commission was appointed in 1859 to inquire into the working of the Act. Its report, with two large volumes of conflicting evidence, has thrown little light on the vexed question. The *bona fide* traveller has also been a source of infinite perplexity to magistrates. It seems now that seven miles is the distance which requires to be travelled in order to constitute *bona fides* on the part of a traveller in Scotland. English law is more rational, as it holds that any exercise sufficient to make refreshments desirable constitutes a 'traveller' under the corresponding English Acts. See in English law, BEER ACTS, INNKEEPERS, HOTELS, LICENSED VICTUALLERS, LICENSING ACT

Forbidd'en Fruit (*Citrus Paradisi*), a species of the genus *Citrus*, belonging to the *Aurantiaceæ* or orange order, also known by the name 'Adam's apple.' The Shaddock (q. v.) (*C. decumana*), another species of *Citrus*, is sold under the name of F. F. in the shops. *C. Paradisi* is common on the Continent, and appears to have been originally brought from China. The fruit is pear-shaped and has an irregular surface. The rind is thick, and constitutes the chief part of the fruit, the pulp being present in small quantity, and of an acid taste. The name F. F. has been occasionally given to the fruit of the *Tabernæmontana dichotoma* of Ceylon, a plant nearly allied to the *T. utilis* or cow-

tree of Demerara, both species belonging to the Dogbane order (*Apocynaceæ*).

Force, according to Newton, is any cause which alters or tends to alter a body's state of rest or of uniform motions in a straight; and the change of motion is proportional to the impressed force, and takes place in the direction in which the F. acts. (See MOTION, LAWS OF.) This at once gives a method for measuring F., and implies that forces are to be composed and resolved in precisely the same manner as velocities, or indeed as any directed quantities. (See QUATERNIONS.) Now, change of motion is an evidence of a transformation of energy from a less to a more apparent form, and is the direct consequence of such a transformation, so that our definition leads us to regard F. as merely a convenient term for transformation of energy, and as having, therefore, no objective reality. When the effects of forces acting on a material system mutually balance, the result is equilibrium, and the study of this branch of dynamics is called Statics (q. v.). See ENERGY.

Force and Fear, if of sufficient degree, are grounds for the reduction of a contract. A threat of causing annoyance, as by bringing an action at law, is not sufficient to vitiate an agreement. But the requisite degree always depends on the circumstances and relative position of parties. It is generally held that a contract obtained by force or fear is not *ipso jure* void, but only voidable; from which it will follow that the wrong-doer can give a good title to a *bona fide* purchaser. See COMPULSION, CONSENT, EXTORTION.

Forcelli'ni, Egid'io, an eminent Italian lexicographer, was born near Padua, 26th August 1688. Although his education was so much neglected that he had almost reached manhood before he commenced regular study at the seminary of Padua, his industry and abilities soon attracted the attention, and secured him the lifelong favour, of Facciolati, its chief. The two co-operated in the production of a great Latin dictionary, entitled *Totius Latinitatis Lexicon Consilio et Cura Jac. Facciolati, Opera et Studio Æg. Forcellini Lucubratum* (4 vols. Pad. 1771). F. died at Padua, 4th April 1768, three years before the publication of their great work. Various editions of it have since appeared, the most complete being that of Furlanetto (Pad. 1828–31). It is the basis of all later lexicons of the Latin tongue, and is really a splendid treasury of scholarship and skill. Two new editions have recently appeared in Italy, that of Corradini (1859 *et seq.*), and De Vit (1860 *et seq.*).

For'ceps (Lat.), in surgery, are pincer-like instruments used for seizing, cutting, or removing substances that cannot be readily got at by the fingers. A complete set of F. are employed in tooth-drawing. Special kinds are required for securing a bleeding artery, extracting bullets, cleansing internal sores, assisting delivery in difficult midwifery cases, &c. Bones of great thickness can be cut by Liston's F.

For'cible En'try, in English law, is the public offence of violently taking or keeping possession of land or of a tenement without legal authority. The corresponding Scotch law terms are Ejection and Intrusion (q. v.).

For'cing, in horticulture, consists in stimulating the vegetation and growth of native or acclimatised plants at seasons other than their natural period of activity. It is practised by the application of artificial heat in hothouses and F. frames, and is resorted to in order to obtain fresh vegetable products in succession during periods when they cannot be procured by cultivation in the open air. In Great Britain F. is extensively prosecuted for obtaining early crops of culinary plants and vegetables, such as rhubarb, potatoes, and green peas.

Ford, John, an Elizabethan dramatist, was the second son of a Devonshire gentleman, and was born at Ilsington, N. Devon, in 1586. He entered at the Middle Temple in 1602, and in 1606 published *Fame's Memorial*, an elegy on the Earl of Devonshire. He was never called to the bar. As a dramatist he produced *The Lover's Melancholy* (1628), a beautiful romantic comedy; *'Tis Pity She's a Whore*, and *The Broken Heart* (1633), two tragedies of intense power, which are F.'s greatest works; *Love's Sacrifice*, a tragedy (1633); *The Chronicle Historie of Perkin Warbeck* (1634), an historical drama; *The Fancies Chaste and Noble*, and *The Lady's Trial*, comedies (1638). F. was a part author with Dekker, and probably with Rowley, in the domestic tragedy entitled *The Witch of Edmonton* (1623), and his masque *The Sun's Darling* (1624) was seemingly founded on Dekker's *Phaeton*. He appears to have retired to his birthplace before his death in 1640. The genius of F. is profound and sombre, but limited. He is wanting in variety, ease, and lightness; of humour and wit he has almost none, his comic scenes being the grossest and most tedious in the Elizabethan drama. As a tragic poet, however, he depicts passion with unerring subtlety and thrilling force. F.'s language is pure and vigorous; his verse has neither the effusive sweetness nor the charming felicities of Fletcher's; it is limpid and equably musical, though at times somewhat hard and unspontaneous. See *The Works of F.* by Gifford, new ed. by Dyce (3 vols. 1869), Swinburne's *Essays and Studies* (1875), Minto's *English Poets*, and Ward's *English Dramatic Literature* (2 vols. 1875).

Fords (from Old Eng. *faran*, 'to go,' hence 'to cross') are shallow parts of a river, which can be crossed simply by wading, without the aid of a bridge or a boat. They are of special importance in military operations; and in choosing a ford, great consideration must be given to its position, its depth in relation to the flow of water, the nature of its bottom, and the manner in which it may possibly be affected by changes of season, &c. For infantry the depth should not exceed 3 feet, and for cavalry 4 feet. Many of our towns, such as Oxford, Bedford, Bradford, Stratford, &c., indicate by their names their own origin, as well as the position of ancient and important F. now superseded by bridges.

For'dun, John of, a 14th c. chronicler, belonging (according to the slender authority of Camden) to Fordun, Kincardineshire, who is supposed to have died about 1385. He was probably a chantry priest of Aberdeen Cathedral. F. wrote what is now known as a *Scotichronicon*, or Chronicle of Scotland, tracing the history of the Scots from the times of Noah to 1153. He had collected additional materials before his death, which passed into the hands of Walter Bower, Abbot of Inchcolm, who carried the Chronicle of F. as far down as 1437, and whose work in 16 books, bearing the title of *Scotichronicon*, appeared between 1440 and 1447. A comparison of Bower's so-called 'Continuation' with the best MSS., especially with the Wolfenbüttel MS., has revealed the startling fact that Bower has so grossly tampered with the text of F. that the original is often unrecognisable and its character completely misrepresented. The best, indeed the only valuable, edition of F. is by Mr. Skene (Edinb. 1871) in the series of *The Historians of Scotland*. The researches of this profound and penetrating scholar must compel the re-writing of the early period of Scottish history.

Fore'castle (pron. *foks'le*), in a ship, strictly an elevated foredeck (see DECK) above the maindeck or the spardeck. Vessels are not frequently built with such a F. now, and the name is generally given to that portion of the fore part of the ship which constitutes the quarters for the crew.

For'eign Attach'ment. A defendant arrested abroad on an English judgment will in England be held to bail in action on the judgment. An English creditor may attach property in Scotland belonging to his debtor resident in England. With reference to Scotch law, see ARRESTMENT and ARRESTMENT FOR FOUNDING JURISDICTION.

Foreign Bill of Exchange. A bill is said to be foreign when drawn by a merchant abroad upon his correspondent in England, or the reverse; or when it is drawn and accepted abroad. Formerly, foreign bills were held by the law to be more important than inland ones, but now they are on nearly the same footing. Every bill drawn in this country must be stamped, and a bill drawn abroad must be stamped before it is presented for payment and before it is negotiated. In enforcing a bill drawn and accepted abroad, the courts of the United Kingdom will hold that whatever relates to the nature of the obligation—*ad valorem contractus*—is ruled by the law of the country where the contract is made, but that the mode of remedy is according to their own forms. See BILL OF EXCHANGE.

Foreign Debts, Recov'ery of. See DEBTS, RECOVERY OF; ENGLISH DEBT.

Foreign Enl'st'ment Act. Under this statute of 1870, any British subject who, without the licence of Her Majesty,

enlists in the service of any foreign state at war with any friendly state, or who induces another to do so, is guilty of an offence punishable by fine and imprisonment. The master or owner of any ship who takes illegally-enlisted persons on board, is guilty of an offence punishable in the same way. Penalties are also imposed on any one who, without Her Majesty's leave, builds, or agrees to build, any ship for the service of a foreign state at war with a friendly state. The Act gives special power to the Secretary of State for carrying out its provisions. It makes regulations with regard to foreigners enlisting in the Queen's service.

For'eigner. See ALIEN.

Foreign Law, Applica'tion of. It is provided by 22 and 23 Vict. c. 63, that if, in any action depending in any court of Her Majesty's dominions, the court shall think it expedient to ascertain the law in any part of the empire applicable to the case, a remit for the purpose may be made to the court having requisite jurisdiction. Her Majesty in Council, or the House of Lords on appeal, may adopt or reject the legal opinion so procured. By 24 Vict. c. 11, similar facilities are given for ascertaining, under similar circumstances, the law of any foreign country. No court in the United Kingdom will review the judgment of a foreign court, or allow a new suit to be opened on the matter affected by the judgment. In America the rule is the same. In England, and in most countries, foreigners may sue each other on the same terms as natives do. The French law courts, however, do not hold that they have jurisdiction in personal questions between undomiciled foreigners, except in commercial affairs. See DEBTS, RECOVERY OF ABROAD; ENGLISH DEBT; FOREIGN ATTACHMENT; FOREIGN BILL OF EXCHANGE; CONFLICT OF LAWS; JURISDICTION; DOMICILE; INTERNATIONAL LAW.

Fore'land, North (the *Cantium* of Ptolemy), is a chalky headland, 190 feet high, in the N.E. extremity of Kent, 2 miles E. of Margate. It has a fixed light visible at a distance of 24 miles.—**South F.**, a promontory, also of chalk, 16 miles S. of the N. F., and between Deal and Dover. It supports two fixed lights, at an elevation respectively of 380 and 275 feet above the sea. Between the two Forelands are the Downs and the Goodwin Sands.

Foreshort'ening, in painting and drawing, is the representation in correct perspective of an object presented obliquely to the eye, and the effect should be to give the object the appearance of projecting from the canvas. Cimon of Cleonæ was the first to apply the method to the human figure in any attitude, and in more recent times the art has been carried to perfection by Raphael, Angelo, Tintoretto, and Correggio.

For'est Fly (*Hippobosca*), the name given to flies belonging to the family *Hippoboscidæ* of the *Diptera* (q. v.). In this family the head is distinct, the legs short, and the fifth joint of the tarsi longest. The wings are large, and the nervures or supporting ribs do not extend to the tip. The *H. equina* is the most familiar species. It receives its popular name from its inhabiting forests, and its specific name of *equina* from its attacking horses by means of its suctorial mouth. The F. F. is about one-third of an inch in length, and is of brown colour, with yellow markings on the thorax. The eggs are retained within the body of the female until the larvæ are hatched, and ready to pass into the pupa stage.

Forest Mar'ble, a local deposit in the southern and midland counties of England, belonging to the Lower Oolites of the Jurassic period, and overlying the Great Oolite group. It consists of hard limestones, marls, shales, and fine oolitic freestone, and contains numerous lamellibranch shells characteristic of this period.

Forest Oak (*Casuarina torulosa*), a species of Australian trees, belonging to the *Casuarinaceæ* or beef-wood order. They are named beef-wood trees from the dark-red colour of their wood, which is hard and heavy, and used for ornamental upholstery.

Forests, Chas'es, Parks, and Warr'ens. By the common law of England, the possessor of land has the exclusive right to all the wild animals found upon it, and he may pursue and kill them. Besides the absolute right which the owner of land has over the soil, there may be a privilege of taking or killing wild animals to the exclusion of others, in virtue of a franchise to have a forest, chase, park, or warren. A forest is a royal domain for the preservation of the Queen's beasts and fowls of forest, and is subject to its own laws, courts, and officers. Before the *Charta de Foresta*, the sovereign could make a forest of any extent over the lands of his subjects. It is the highest franchise relating to game. There are sixty-nine forests in England, the four principal of which are New Forest on the Boldre, Sherwood Forest on the Trent, Dean Forest on the Severn, and Windsor Forest on the Thames.

A *chase* is a franchise whose nature is between that of a *forest* and that of a park. It may be held by a subject, and is governed by the common, not by the forest, law. It is not enclosed. A man may have the right of chase over the ground of another, with privilege to keep royal game on it, protected even from the owner of the land. There are, we believe, thirteen chases in England.

To constitute a *legal* park there must be a royal grant; it must be enclosed by pale, wall, or hedge, and it must be stocked with deer; and if the deer are all killed, it is no longer a legal park, which is composed of *best venison* and *enclosure*, and failure in one is a total disparking. There are in England 780 parks.

The *warren* is a place privileged by prescription or royal grant for the keeping of beasts and fowls of the warren, which are hares and rabbits, partridges and pheasants. Some add quails, woodcocks, and waterfowl. Twenty years' undisturbed exercise of a claim of a warren or park will afford presumptive evidence of right in the party who has exercised it for the period. The owner of a warren may lawfully kill any dog found injuring the warren.

The rights of any forest, chase, or warren are not affected by the Game Laws (q. v.) The franchises mentioned above may be destroyed by reversion to the crown, or by surrender or forfeiture in consequence of a breach of the trust for which they were granted. In Scotland, lands granted by the crown with a right of forestry carried all the privileges of a royal forest, which were very oppressive to the country, and accordingly the right was reprobated in 1680 by the Court of Session. Nevertheless, the pretensions of royal foresters have survived to present times. In 1862 the Duke of Athole, in virtue of his supposed right of forestry, claimed the right to prevent his neighbour, the Laird of Lude, from killing deer on his own lands, and maintained that he, the Duke, and his servants were entitled to enter the lands of Lude and drive any deer found on them into the forest of Athole. Both points were decided against the Duke (1st March 1862).

For'far, the capital of Forfarshire, in the valley of Strathmore, near a small lake, 15 miles N.E. by N. of Dundee by railway. It has a large parish church, with a spire 150 feet high, a handsome townhall, and a considerable manufacture of brown linen and 'brogues.' Pop. (1871) 11,031. F., along with Montrose, Arbroath, Brechin, and Bervie, sends one member to Parliament. It is supposed to be the ancient *Orrea*, and received a royal charter in the reign of David I. There was formerly a royal castle here.

For'farshire, or **Ang'us,** a county on the E. coast of Scotland, bounded N. by Kincardine and Aberdeen, E. by the North Sea, S. by the Firth of Tay, and W. by Perthshire. Area, 890 sq. miles; pop. (1871) 237,567. It is entered in the N. by many spurs of the Grampians, known as the Braes of Angus, alternating with many romantic glens, as the Esk, Clova, Prosen, and Isla. The flat fertile belt of Strathmore bisects F. from S.W. to N.E., while to the S. the Sidlaw Hills run at a distance of 8 miles from, and in a direction parallel to, the Firth of Tay. The chief rivers are the Isla, an affluent of the Tay, and the N. and S. Esks. F. has a coast 45 miles long, part of which, from Arbroath to the promontory of Redhead, is a line of sandstone cliffs, worn into many deep caverns. Buddon Ness juts out at the entrance of the Tay Firth, and 13 miles to sea rises the Bell Rock Lighthouse. The soil of F. is partly fine alluvium, partly peat; and the chief formation is Old Red Sandstone. In 1873, 95,694 acres were under corn, 52,098 in green crops, 71,341 under various grasses, and 26,933 in permanent pasture. The chief manufactures are linen and jute, the former chiefly at Arbroath, the latter at Dundee. Among the towns are F. (the

capital), Brechin, Montrose, and Kirriemuir. The county sends one member to Parliament, the burghs two. Angus, which was a possession of old Celtic Maarmors, is known as an earldom in the 12th c., and became subsequently a seat of the Umphravilles, the Stewarts, and Douglases. The antiquities are numerous, including several Roman camps, a vitrified fort at Finhaven, many sculptured stone pillars, the round tower and cathedral at Brechin, the ruins of Arbroath Abbey, Restennet Priory, the 'Bonnie House of Airlie,' and Edzell, a noble ruin overlooking the North Sea. The old baronial castle of Glammis is one of the finest in Scotland. The new residence of the Earl of Airlie, Cortachy Castle, is imposing, but does not occupy a commanding site.

For'feiture and Corrup'tion of Blood was formerly a penalty consequent on Attainder (q. v.) for treason or felony.

Forfeiture of Lands was in feudal law the penalty incurred by a tenant for an act of disloyalty to his over-lord.

Forfic'ula. See EARWIG.

Forge (Fr. *forge*, Prov. *faurga*, from Lat. *fabrica*, 'a workshop'), a place in which wrought-iron in the shape of bar or scrap is fashioned into the forms required in construction. Where only light work has to be done, the F. is generally called a *smithy*. In such a F. the furnaces for heating the iron are open hearths, air being supplied to each fire through a blast-pipe entering at the bottom of it. In the smithies of engineers a fan or Blowing Machine (q. v.) is employed to produce the blast, each hearth having a valve by which to regulate the quantity of air passing through it. Each hearth is attended to by at least two men, a smith and a striker, whose names sufficiently show their respective shares in the work. All the smaller forgings, which are hammered by hand, are made by these men. All smithies, except the smallest, are furnished with one or more Steam-Hammers (q. v.) to be used for larger work. In the F. proper, heavy forgings, such as crank shafts, armour plates (when not rolled), rudder posts, wrought-iron guns, &c., are made. Here large air-furnaces take the place of the open hearths, and all hammering is done by large steam-hammers instead of by hand. The 'portable F.' is a small iron hearth supported upon a movable framework (generally upon wheels), and fitted with a pair of bellows, or a small blowing machine worked by hand.

For'gery ('the art of fabricating') is the fraudulently making, or uttering of a document to the injury of another, or the making or falsifying of a stamp to the loss of the revenue. To constitute F., it is not necessary that the whole instrument should be fictitious. Making a fraudulent insertion, alteration, or erasure in any material part of a true document, by which another may be defrauded, the fraudulent application of a false signature to a true instrument, or of a real signature to a false instrument, the alteration of the date of a bill after acceptance with fraudulent intention, are forgeries. A note being payable at a banker's who fails, to fix a piece of paper over the name of that banker, writing over it the name of another banker, is F. So is it also to put a fictitious signature to a bill of exchange. The essence of F. is an intent to defraud; therefore where the imitation of a signature or alteration of a writing can injure no one, the offence is not committed; but if the act can injure any one, there will be a presumption of fraudulent intention. If the counterfeited document be such as would be ineffectual if real, the crime may still be committed. Uttering (q. v.) is essential, and merely to show the forged instrument is not uttering. To have, without lawful excuse, the proof of which lies on the accused, forged-bank notes, or any appliances for making them, is punishable with penal servitude. (See BANK-NOTE.) Knowingly to make a false entry in any public register is F. Further provisions have been made against the crime by the F. Act (1870), which imposes severe penalties on the F. of stock certificates issued under the National Debts Act, and on the personation of owners of stock, and on engraving plates for stock certificates. The extreme penalty for F. is now penal servitude for life. Seven to fourteen years is commonly the term.

Forget'-me-not (*Myosotis palustris*), a well-known species of plants belonging to the *Boraginaceæ* or borage order. It is sometimes known also by the name of 'scorpion grass,' from its peculiar inflorescence. F. is a herb of annual or biennial nature. The calyx is five-cleft, and the corolla is *rotate* or *salver-shaped*. The flowers are blue, the leaves being alternate, and the stem of rounded form. An allied species is *M. sylvatica*, which has its calyx covered with stiff expanded hairs. *M. Azorica* occurs at the Azores, and *M. versicolor* is a common garden weed, the flowers of which are first coloured yellow, and then develop a blue colour. *M. Alpestris* is a mountain-growing species.

Forget-me-not (*Myosotis palustris*).

Forisfamilia'tion is a term of Scotch law denoting the separation of a child from the family of its father. Where a child has a separate estate from the father, the profits of which become his own, he is held to be forisfamiliated even though he remains in his father's family. F. takes place when a child is married or lives in a separate family with the consent of its father. The term is also used to signify either an onerous or gratuitous renunciation of *legitim* by a child. See LEGITIM, AGE.

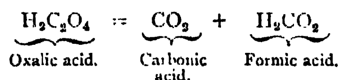
Fork (Old Eng. *forc*; comp. Lat. *furca*), an instrument with two or more metal prongs, used, when small, at table for eating with, and, when large, in several farming and gardening operations. The nations of antiquity generally put their fingers to the use to which a table-F. is now applied; but a two-pronged bronze F. was found at Nineveh by George Smith in 1874. Previous to this discovery, nothing had been known of the existence of forks in times so remote. They are first heard of as an article of luxury brought by a Greek princess from Constantinople to Venice at the end of the 11th c. The name is occasionally met with in inventories of the 12th and later centuries, but the paucity of the references only goes to prove the extreme rarity of forks before the 15th c. In the following century they were in general use in Italy; the gastronomic art had then reached the greatest degree of magnificence and refinement in Venice, Florence, and Rome. A table instrument formed of a spoon and a two-pronged F. joined together was known in England long anterior to that time, even in the Pre-Norman epoch, but its use was for serving, not feeding. Coryate, the English traveller, visited Italy in 1608, and in his *Crudities* (1611) gives an interesting though quaint account of the use of the 'little F.' in that country. On his return to England he continued its use at meals, and was ridiculed for doing so. Slowly, thereafter, the F. became general at table, not however without opposition on the part of the clergy, who denounced the innovation as 'wicked,' and 'an abominable violation of primitive manners.' The washing of the hands before and after meals, which was rendered necessary by the primitive mode of eating, then fell into disuse. In Ben Jonson's comedy *The Devil is an Ass* an allusion is made to that circumstance—

> 'The laudable use of forks,
> Brought into custom here, as they are in Italy,
> To the sparing of napkins.'

The earliest forks were made of silver, and the introduction of others with steel prongs assisted in spreading the custom of using them among all classes. Asiatics do not use the F.; in China *chopsticks*, two slender rods of wood or ivory, take its place. An instance of the use of the F. among savages is reported of the Fijians, who twenty-five years ago were the most inveterate cannibals known; when eating human flesh, a large F., made of the hard wood of the *Casuarina*, was used, whereas at ordinary repasts the mode more befitting savages was followed.

For'li (the Roman *Forum Livii*), a walled town and capital of a province of the same name, N. Italy, between the rivers Ronco and Montone, at the base of the Appenines, 40 miles S.E. of Bologna by railway. It is the seat of a bishop, and has many splendid buildings, chief among which are the Palazzo

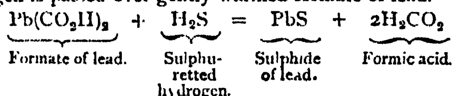
Guerini, designed by Michael Angelo, and the cathedral, containing pictures by Carlo Maratti, Guido, &c. There are some silk and salt industries, and a trade in hemp, corn, woad, and carthamus. The sulphur mines of F. produced (1874) 24,700 tons of sulphur. Pop. (1872) 38,480. F. was founded by Marcus Livius Salinator in 207 B.C. In the Middle Ages it formed a republic, and suffered greatly in the time of the Guelph and Ghibelline factions.



Forlorn' Hope, in warfare, is the name given to a body of picked troops or volunteers devoted to some desperate enterprise. The corresponding name in German is *Die verlornen posten*, in French *Les enfants perdus*.

For'ma Pau'peris, in the law of England and of Scotland, is the term denoting the mode in which an action may be maintained by one who is too poor to follow the usual way. In England it is provided by statute that any one having just cause of suit, who can take oath that, under deduction of his debts, his possessions are not worth £5, shall be entitled to sue without paying any fee to counsel, attorney, or clerks in court. The *just cause* must be certified by a barrister. If the case go against the person so suing, he may be imprisoned for the defendant's costs. The statute does not apply to defendants; but any one arrested on a *capias*, or information relating to the customs, may defend in F. P. In Scotland the privilege of so suing or defending is conferred by the court, on being satisfied that the applicant has *Probabilis Causa* (q. v.) (See also POOR'S ROLL.) While these arrangements for securing the administration of justice to the poor are perhaps on the whole commendable, their operation is frequently attended with considerable hardship to the opposing party. If the subject of dispute is inconsiderable, as it generally is, the opponent of the pauper knows that, however the case may be decided, he, the opponent, must be a loser, as he cannot get costs from the pauper. Thus, so far as money is concerned, it is better for him to abandon his case. Absolute paupers apart, when an unscrupulous agent has a client who can pay nothing if he loses, and the opponent can pay—or, in legal slang, is 'worth powder and shot'—the injustice that may be perpetrated in the position is evident; and it is perpetrated accordingly.

Forma'tion, in geology, is a somewhat vague term applied to a group or series of conformable strata, differing in lithological character and even in their fossil contents.



Formi'ca. See ANT.

For'mic A'cid derives its name from the fact that it is secreted by the ant (*formica*). When the insect is irritated it ejects the acid, which is at once recognised by its peculiar odour and by the stinging sensation it produces if it comes in contact with the skin. It also occurs in the free state in the nettle (*Urtica urens*), and is the cause of the disagreeable effect produced when the plant is touched. It may easily be obtained in a dilute state by distilling oxalic acid with its own weight of glycerine. The glycerine takes no apparent part in the decomposition of the oxalic acid, but simply exercises a catalytic action (see CATALYSIS) whereby the oxalic acid is split into formic and carbonic acids.

$$\underbrace{H_2C_2O_4}_{\text{Oxalic acid.}} = \underbrace{CO_2}_{\text{Carbonic acid.}} + \underbrace{H_2CO_2}_{\text{Formic acid.}}$$

In order to prepare it pure and anhydrous, dry sulphuretted hydrogen is passed over gently warmed formate of lead.

$$\underbrace{Pb(CO_2H)_2}_{\text{Formate of lead.}} + \underbrace{H_2S}_{\text{Sulphuretted hydrogen.}} = \underbrace{PbS}_{\text{Sulphide of lead.}} + \underbrace{2H_2CO_2}_{\text{Formic acid.}}$$

Pure F. A. is a pungent liquid, having a peculiar odour, and exercising a very corrosive action on the skin. It boils at 99° C., and crystallises when cooled to − 6° C. Its only compound of any practical importance is formic ether or artificial essence of rum, which is prepared by distilling a mixture of starch, alcohol, binoxide of manganese, and sulphuric acid.

Form'ing's Island, in the Pacific, to the N. of the Sandwich Islands, has a good harbour, on which account it was occupied by the English in 1860.

Formo'sa (Span.; Lat. *formosa*, 'beautiful;' Chinese, *Taiwan*, 'terrace;' Malay, *Pekan* and *Pakkando*), an island in the Chinese Sea, 90 miles off the province of Fu-kien, from which it is separated by the F. Channel. It is 237 miles long, with an average breadth of 70 miles, and is of great natural beauty. A central range, rising to about 12,000 feet, divides F. into a fertile western plain, and an eastern Alpine region. The mountains are of volcanic origin, fantastic in outline, and cleft by deep gorges running up from the sea, clothed with bright verdure and watered by many cascades. The western plain is cultivated like a garden by Chinese, who have settled there to the number of about 500,000; while the eastern high lands are held by wild tribes named Peppohoans, of Mongolian origin, whose numbers are not accurately known. Rich coal-mines have been opened in the N. of F. by the Chinese, who are encroaching on the E. coast. The mining is carried on very primitively, but much coal is exported to China, especially to Fu-chow. The interior has veins of sulphur and various metals. Besides coal, the chief exports are rice, for which F. is famous, tea, brimstone, timber, &c. The principal places are Tai-wan, the capital, opened to foreigners in 1858, and Ke-lung, a rising port in the N., and the centre of the coal trade. An atrocious massacre of some Japanese sailors who were wrecked on the E. coast of F. in December 1871 compelled the Japanese Government, who could obtain no redress from the Chinese authorities, to invade the island. General Saigo landed in May 1874 with a force of 3000 men, and inflicted severe punishment on the guilty tribes. The Chinese were greatly excited, and for some time war seemed imminent between the two empires, but peace was finally maintained, and on the 2d or 3d of December the Japanese troops withdrew. See *The Eastern Seas, being a Narrative of the Voyage of H.M.S. Dwarf*, by Captain B. W. Bax, R.N. (Lond. 1875).

Forms of Address are as various as the rank of those addressed, and a knowledge of the following may prove useful.

THE ROYAL FAMILY.

The Queen—Superscription, 'To the Queen's Most Excellent Majesty.' Commencement, 'Madam;' conclusion, 'I remain, with the profoundest veneration, Madam, Your Majesty's most faithful subject and dutiful servant.'

The Prince of Wales—Sup., 'To His Royal Highness the Prince of Wales.' Com., 'Sir;' conclusion, 'I remain, with the greatest respect, Sir, Your Royal Highness's most dutiful, most humble, and most obedient servant.'

Princes of the Blood Royal—Sup., 'To His Royal Highness the Prince ——.' Com., 'Sir;' conclusion, 'I remain, with the greatest respect, Your Royal Highness's most dutiful, and most obedient, humble servant.'

The Princess Royal—Sup., 'To Her Royal Highness the Princess Royal.' Com., 'Madam;' conclusion, 'I remain, with the greatest respect, Madam, Your Royal Highness's most obedient, devoted, and humble servant.'

Princesses of the Blood Royal—Sup., 'To Her Royal Highness the Princess ——.' Com., 'Madam;' conclusion, 'I remain, with the greatest respect, Madam, Your Royal Highness's most obedient, devoted, and humble servant;' refer, 'Your Royal Highness.'

Princes of the Blood, embracing the sovereign's nephews and cousins—Sup., 'To His Highness the Prince of ——.' Com., 'Sir;' conclusion, 'I have the honour to be, with great respect, Sir, Your Highness's most obedient, and very humble servant.'

Princesses of the Blood, embracing the Sovereign's nieces and cousins—Sup., 'To Her Highness the Princess —— of ——.' Com., 'Madam;' conclusion, as above, substituting *Madam* for *Sir*.

NOBILITY AND GENTRY.

Dukes—Superscription, 'To His Grace the Duke of ——.' Commencement, 'My Lord Duke.'

Duchesses—Sup., 'To Her Grace the Duchess of ——.' Com., 'Madam.'

Marquesses—Sup., 'To the Most Honourable the Marquess of ——.' Com., 'My Lord Marquess.'

Marchionesses—Sup., 'To the Most Honourable the Marchioness of ——.' Com., 'Madam.'

Earls, Viscounts, Barons—Sup., 'To the Right Honourable the Earl of ——.' 'To the Right Honourable the Lord

Viscount ——.' 'To the Right Honourable the Lord ——.' Com., 'My Lord.'

Countesses, Viscountesses, and Baronesses—Sup., 'To the Right Honourable the Countess of ——.' 'To the Right Honourable the Viscountess of ——.' 'To the Right Honourable the Lady ——.' Com., 'Madam.'

Baronets—Sup., 'To Sir William ——, Bart.' Com., 'Sir.'

Knights—Sup., 'To Sir John ——.' Com. as above.

The Wives of Baronets and Knights—Sup., 'To Lady ——.' Com., 'Madam.'

Sons of Peers—The younger sons of Dukes and Marquesses are also styled Lords, and addressed as such with the addition of their Christian names, as, 'To the Right Honourable Lord John ——.' The younger sons of Earls, and all the sons of Viscounts and Barons are styled Honourable, as, 'To the Honourable Mr. ——.' Com., 'Sir.'

Wives of the Sons of Peers—Sup., 'To the Right Honourable Lady William ——.' 'To the Honourable Mrs. ——.'

Daughters of Peers—Sup., 'To the Right Honourable Lady ——.' 'To the Honourable Miss ——.' Com., 'Madam.'

Privy Counsellors—Sup., 'To the Right Honourable ——.' Com., 'Sir.'

Army and Navy—Admirals when addressed officially have the rank of their flag added to their name and title, as, 'To the Right Honourable the Earl of ——, Admiral of the Red.' Commodores and captains take their rank and title after their designation on the *Naval List*. In the army all officers take their name and title after their rank in the *Army List*.

Governors of Colonies, &c.—Sup., 'To His Excellency Sir ——,' or, 'To His Excellency General ——, Governor of ——,' or, 'Governor and Commander-in-Chief.' Com., 'Sir.'

Archbishops—Sup., 'To His Grace the Lord Archbishop of Canterbury.' Com., 'My Lord Bishop.'

Bishops—Sup., 'To the Right Reverend The Lord Bishop of ——.' Com., 'My Lord Bishop.'

Deans—Sup., 'To the Very Reverend the Dean of ——.' Com., 'Mr. Dean,' or 'Reverend Sir.'

Archdeacons—Sup., 'To the Venerable the Archdeacon ——.' Com., 'Mr. Archdeacon,' or 'Reverend Sir.'

Lord Advocate (of Scotland)—Sup., 'Her Majesty's Advocate for Scotland,' but by courtesy, 'The Right Honourable the Lord Advocate.' Com., 'Sir,' but by courtesy, 'My Lord.'

Lord-Lieutenant of Ireland—Sup., 'His Excellency the Lord-Lieutenant.'

Lord Mayors are three in number, those of London, York, and Dublin—Sup., 'To the Right Honourable the Lord Mayor of ——.' Com., 'My Lord.'

Lady Mayoresses are addressed in the same style as their husbands.

Lord Provost of Edinburgh—Sup., 'The Honourable the Lord Provost.'

See the *Peerages* of Dod, Burke, Lodge, &c., also Kingdom's *Secretary's Assistant*.

Forms of Proced'ure. See PROCESS.

Fornica'tion (Lat. from *fornix*, 'an arch-vault,' because Roman brothels were underground), now usually regarded as an offence, has been at different periods, and in different countries, considered a crime meriting punishment of every degree of severity, including that of death. Among the Jews, F. was, under certain conditions, visited with capital punishment; and among certain religious communities, especially since the Reformation, the offence was prohibited under extreme penalties. By no class of religionists, probably, was F. more severely punished than by the English Puritans and the Puritan settlers in New England. During Cromwell's Protectorate, the Puritans made F. felony, including death without 'benefit of clergy.' Milder laws, however, with respect at least to moral offences, came in with the Restoration, and F., according to Blackstone, was treated with 'a great deal of tenderness and lenity.' In Scotland an Act was passed in 1567 providing that fornicators, whether male or female, shall for the first offence pay a fine of £40 Scots, and stand bareheaded at the market-place for two hours; for the second offence the fine was 100 merks; and for the third offence the fine was £100, and the culprit was also liable to be thrice ducked in the dirtiest pond in his parish, and then banished from it for ever. Scandalously-conducted houses of ill-fame are still punishable in Scotland by the civil authorities, but of 'simple' F. the law takes no cognisance.

Forr'es, an old royal burgh of Scotland, in Elginshire, on the Findhorn, 2 miles from the sea, and 10 miles W.S.W. of Elgin by railway. It stands on an old sea-terrace at the base of the Cleeny Hills, four gravelly elevations, on the highest of which—on the site of ancient fortifications—is the Nelson Tower (66 feet), erected in 1806. F. was formerly the seat of the Archdeacon of Moray, and there still remains a portion of the 'mantle wall' which once surrounded the college or cathedral kirk, and which contains the Paris Port, or bishop's entrance. To the W. are the ruins of a castle, to the E. a rudely-hewn pillar, 25 feet high, called Sueno's Stone, or the 'Stan'in' Stane.' The chief industries are distilling, brewing, and dyeing. F., along with Inverness, Nairn, and Fortrose, returns one member to Parliament. Pop. (1871) 3959.

Forr'est, Edwin, a celebrated American actor, born in Philadelphia, 9th March 1806, first appeared on the public stage at the age of fourteen as Douglas (November 27, 1820). After playing in the chief western cities during a long professional tour, he appeared at the Park Theatre, New York, as Othello, in 1826, and at once achieved reputation. He visited England in 1835, again in 1837, when he married Catherine Sinclair, and a third time in 1845. On the third visit to England the friendly relations that had previously subsisted between F. and Macready were severed; and on the occasion of the professional tour of the latter in America, F.'s partisans were the cause of a riot, 10th May 1849, from which the English tragedian barely escaped with his life. F. continued to play till 1871, after which he gave a few Shakespearian readings. He died at Philadelphia, December 12, 1872. F. added a fine presence to a distinct and even powerful histrionic genius. See W. R. Alger's *Life of E. F., the American Tragedian* (Lond. & Philad. 1877).

For'ster, John, an eminent journalist and biographer, was born at Newcastle in 1812. Educated for the bar, he devoted himself to literature and journalism. He succeeded Charles Dickens as editor of the *Daily News*, but retired from the post in a year. A connection which F. formed with the *Examiner*, during the brilliant editorship of Albany Fonblanque, lasted for eighteen years, F. in the course of it becoming editor in 1846, and retiring from the office in 1856, on his having been appointed the year previous Secretary to the Lunacy Commission. Five years later he became Commissioner in Lunacy. He died 1st February 1876. F. will be chiefly memorable for his historical and biographical works. He devoted himself largely to the period immediately prior to the advent of Cromwell, and in discharge of his duty of 'righting wronged reputations,' as Fonblanque styled it, wrote *Statesmen of the Commonwealth of England* (1831–34), *Arrest of the Five Members*, and the *Grand Remonstrance* (1860), and *Sir John Eliot, a Biography* (1864). F. was the intimate friend of a number of the most eminent literary men of the day, such as Landor, Dickens, and Carlyle. He published a biography of Landor in 1868, and of Dickens in 1871–74. He also wrote a *Life of Oliver Goldsmith* (1848), and shortly before his death published the first volume of a *Life of Swift*.

Forster, Johann Reinhold, a celebrated naturalist and traveller, was born at Dirschau near Danzig, 22d October 1729. Educated for the Church, F. for some time after 1753 officiated as a pastor at Nassenhuben, but being devoted to philosophy, science, and mathematics, was employed by the Russian Government to investigate the condition of a colony at Saratov. He afterwards removed to England, and taught natural history and the French and German languages at Warrington, Lancashire. In 1772 he accompanied Captain Cook in his second voyage round the world as naturalist. On his return in 1775, the University of Oxford conferred on him the degree of LL.D., and three years later he published the results of his botanical observations, and *Observations made during a Voyage round the World*. Some disputes arising between F. and his English friends, he took the position of Professor of Natural History, &c., at Halle, in Saxony, and produced a number of works, of which *Geschichte der Entdeckungen und Schiff-fahrten im Norden* (Frankf. 1784) has been translated into English (1786). F. was a good scholar in classics and literature, and is said to have been able to speak and write seventeen different languages. He died at Halle,

December 9, 1798.—**Johann Georg Adam F.**, son of the preceding, was born at Nassenhuben, 26th November 1754. He was with his father in Russia and England, accompanied him in his voyage along with Captain Cook, and became Professor of Natural History first in Hesse Cassel (1778), and then in Wilna (1784). He settled in Mainz as a bookseller, and as librarian to the Elector. In 1790 he accompanied Alexander von Humboldt to Britain, France, and the Netherlands; finally he embraced republican opinions, and in 1793 was sent to Paris to solicit the incorporation of Mainz with the French Republic. When Mainz was taken by the Prussians, F. appears to have lost his books, MSS., &c., and was on the point of leaving for India and Turkistan, when he died in Paris, January 12, 1794. He wrote on ethnology, philosophy, politics, geography, and natural history. A collection of his letters was published by his widow, a daughter of Heyne (2 vols. Leips. 1828–29), and his complete works were edited by his daughter (9 vols. Leips. 1843–44). See König's *Clubisten in Mainz* (3 vols. 2d ed. Leips. 1857), and *F.'s Leben in Haus und Welt* (Leips. 2d ed. 1858), Moleschott's *F.* (2d ed. 1862); Klein's *F. in Mainz* (Gotha, 1863), and G. Forster's *Briefwechsel mit S. T. Sömmerring* (Brunsw. 1877).

Fort, Fort'ress (Lat. *fortis*, 'strong'), a place of strength, within the defences of which a small body of men may repulse a considerable force. The name *fort* is commonly applied to a star-shaped or a bastioned work of military engineering; the term *fortress* is of wider application, and may be used to designate a group or series of fortified works. See FORTIFICATION.

Fort, in British North America, is the name applied to the different posts or trading stations of the Hudson's Bay Company (q. v.) or other fur-trading corporations. These posts, usually log-built structures with sleeping, dining, and store rooms, are not in any sense strongholds.

Fort-Ad'jutant, an officer intrusted with the same duties in a fort as are discharged by a regimental adjutant on service. In 1876–77 the number of fort-adjutants was nine. The regimental pay of an adjutant is 17s. 6d. per diem, and fort-adjutants receive 4s. 9d. per diem as staff officers.

Fort Augus'tus (Gael. *Cilla-Chuimein*, 'the cell or church of Cumin,' probably the 'Cumineus albus' who was abbot of Iona 657-669), a small fort at the S. end of Loch Ness, 29 miles from Inverness, and in the very centre of the great glen of Scotland, built in 1718 with the view of bridling the N. Highlanders. It received its present name in 1746, in honour of the Duke of Cumberland. F. A. is a quadrangle with bastions, and was well fitted for about a hundred soldiers. It has been recently sold by Government to Lord Lovat, who has converted it into a Roman Catholic monastery.—F. A. is also the name of a small and very poor village in the immediate vicinity of the fort.

Forté (Ital. 'strong or loud'), used in music as a mark of expression.

For'tescue, a noble English family said to have sprung from a certain Richard *le Fort* who accompanied William of Normandy to England, and at the battle of Hastings covered him with his shield, on account of which he received the name *Fort-escu* ('strong shield'). This pretty legend is embodied in the motto of the F. arms, *Forte scutum, salus ducum.* The most distinguished member of the family was **Sir John F.**, son of one of the bravest generals of Henry V. He was born about 1395, studied at Oxford, and in 1442 was Chief-Justice of the King's Bench. On the outbreak of the Wars of the Roses, he sided with the Lancastrians, and in 1461 fled with Queen Margaret to the Continent, where he wrote about 1463 for the young Prince Edward his famous treatise in dialogue, *De Laudibus Legum Angliæ* (best ed. Amos, Camb. 1825). In 1471 F. returned to England, submitted to the House of York, and died in 1485 at his estate of Ebrington in Gloucestershire. Another valuable work of F.'s is *The Difference between Absolute and Limited Monarchy* (Lond. 1714). In both of these F. proves himself a sound English Constitutionalist. **Sir Hugh F.**, a lineal descendant of Sir John, became Baron F. in 1746, but the first earl in the family was **Hugh F.** (born 1753, died 1841). **Hugh, second Earl of F.** (born 1783, died 1861), took an active part in the great debates on the first Reform Bill, and was Lord-Lieutenant of Ireland till the fall of the Whig Government in 1841. **Hugh, third Earl of F.**, born 4th April 1818, was educated at Harrow, entered Parliament in 1841 as Viscount Ebrington, was called to the Upper House on the death of his father, and has throughout his public career been an indefatigable sanitary reformer. He has written several pamphlets on social, political, and educational questions. The family of F. is noted for its fidelity to the Liberal party.

Fort George (Gael. *Aird-nan-saor*, 'height of the carpenters'), a fort in the county of Inverness, on a sand-spit in the Moray Firth, 9 miles N.E. of Inverness. It has barrack accommodation for 2000 men, and unlike the two smaller forts at one time connected with it, Fort Augustus and Fort William, is still kept in use. It mounts seventy guns, and is very scientifically defended, but would be of little avail against the artillery of the present day. It was built shortly after the Jacobite rising of the '45, at a cost of £160,000.

Forth, one of the most picturesque rivers of Scotland, rises in the N.W. of Stirlingshire, and has a direction mainly E. by S., forming part of the boundary between the shires of Perth and Stirling, and expanding into the Firth of F. near Alloa, after a very sinuous course of 70 miles. Its upper waters are the Duchray, 16 miles long, from the E. base of Ben Lomond, and the Avendhu, 12 miles, from the W. side of Ben Venue. The latter flows through Loch Chon, Dhu, and Ard, and the united stream leaves the romantic region of the Highlands at Aberfoyle. From the N. the F. receives the Teith, Allan, and Devon; the principal town it passes is Stirling, to which it is navigable for vessels of 100 tons. Below Alloa the estuary gradually widens, occasionally contracting, as at Queensferry (three-quarters of a mile), till it reaches its greatest breadth of 25 miles between Musselburgh and Largo Bay. The *Firth of F.* separates the counties of Stirling, Linlithgow, Edinburgh, and Haddington on the S. from Clackmannan, Perth, and Fife on the N.; and the chief towns on its shores are Leith, Portobello, North Berwick, Queensferry, Grangemouth, Culross, Burntisland, and Kirkcaldy. It receives from the S. the Carron, Avon, Almond, and Esk, from the N. the Leven, and its waters have a maximum depth of 30 fathoms. St. Margaret's Hope, above Queensferry, is one of the safest of British roadsteads. See *Guide to the Firth of F.*, by Messrs. Reid & Son (Leith, 1876).

Fortifica'tion, the art or science of strengthening a military position by means of defensive works, is resorted to equally by forces in attack and on defence. In warfare, the ultimate purpose of defensive works is to oblige the enemy to fight under the most disadvantageous circumstances, mainly by making use of natural or artificial cover as a protection against his fire, and as a shield from under which counter-fire may be delivered. Natural F. is the utilisation of natural objects—rivers, marshes, forests, ravines, &c.—to delay the assault of an enemy, and to render it more or less ineffectual when made. Artificial F. is constructive, and has been described as military architecture, or the art of strengthening natural obstacles to an enemy's advance, or, where such natural obstacles do not exist, of constructing works to serve the same purpose, by the skill of the engineer. The latter division of the subject falls to be considered under the two headings *Permanent* and *Field or Temporary F.* The purposes of both permanent and field works are identical, and in their construction the same principles are brought to bear. The principal features of both are a ditch to impede the enemy's assault, and a parapet on the side of the ditch occupied by the defence to afford the defenders protection against the enemy's fire, and at the same time enable them to deliver their own fire without exposing themselves to the enemy's marksmen. Field-works, thrown up for a temporary purpose, by unskilled labour, and with such materials as the locality affords, are often rude and slight; permanent fortifications, however, intended for the permanent protection of countries, capitals, arsenals, dockyards, &c., are deliberately built by the most skilful engineers, and with the best materials the age and the country can command, and are, so far, perfect as works of military engineering.

Permanent Fortification.—In the history of military science, the art of defence has gradually developed so as to meet the exigencies of a gradually-developing art of attack. In early days enclosing walls—the original *enceinte*—were considered sufficient to protect a city against a besieging force. Later the walls were strengthened by projecting towers at bowshot distance from each other, and from the loopholes of which an effective flank fire could be delivered along the face of the wall. After the inven-

tion of gunpowder and the introduction of artillery, the defensive wall and tower were lowered, so that guns mounted upon them might be fired at a level low enough to sweep the ground occupied by the enemy, and thus the tower became practically a *bastion*, and one of the chief features of modern F. was created. The bastioned system of F., due originally to the ingenuity of the Italian engineers of the early part of the 16th c., was developed by the genius of Vauban (q. v.), Cormontaigne, and other engineers, and all the French and many of the Continental fortresses of our own day are built on this system. The favourite type of permanent F. at present, however, the adoption of which has doubtless been due to the changed conditions of war consequent upon recent improvements in artillery, was advocated a century before Vauban's day by no less a person than Albrecht Durer, who in his work on F. in 1527 recommends what has always been known as the 'polygonal system.' This system was first adopted in Germany early in the present century, was subsequently employed (with modifications) by Belgium, and more recently by Great Britain in the construction of the defences of the great English dockyards. Of the polygonal system the chief characteristics are that the lines of parapet are traced with reference to the space they have to enclose and the direction from which it is probable an attack would be made, and not with reference to the reciprocal *flank defence of the ditches*. Still, in the polygonal system, the defence of the ditch is provided for, in the event of its being reached, by placing casemated buildings (masked batteries in fact) within the ditches, and in such positions as to sweep them to right and left, or otherwise, by reverse galleries in the counterscarps. The profile and arrangements of the works of the bastioned and polygonal systems of F. are similar though not identical. The accompanying figure will readily familiarise readers with the names, relative positions, &c., of the principal parts of the Enceinte (q. v.) of all regularly-fortified works.

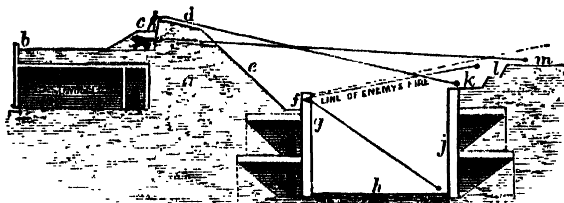


Fig. 1.—Section of Counter-Arched Revetments as adopted in England.

The *rampart* (*a*) is a mound of earth raised above the natural level of the country, and formed of the soil obtained by excavating the ditch, which extends in front of it all round the work. The *terreplein* (*b*) is the platform on which the guns are placed and worked. The *banquette* (*c*) is a tread or step of earth upon which the infantry stand to deliver their fire. The *parapet* (*d*) the highest part of the rampart, is a *breastwork* 30 feet thick and about 8 feet higher than the terreplein, the purpose of which is to protect the troops working the guns and the infantry on the banquette from the musketry and cannon of the enemy. The parapet is pierced with embrasures, usually about 18 feet apart, through which the guns are fired. The *crest* of the parapet (*c*) is usually about 22 feet above the natural level of the country. The *superior* or *upper slope* of the parapet is about 18 feet broad, and has a slope of 1 in 6. The *exterior* or *lower slope* (*e*), the remaining part of the parapet, has a slope of nearly 1 in 3. At the foot of the exterior slope in bastioned works is the *berm* (*f*), a narrow level space or path which affords a means of communication round the outside of the works. The same purpose is served in polygonal F. by the *chemin des rondes*. The *escarp* (*g*) is the inside wall of the ditch, lined with mason-work to retain the earth of the rampart in its place. (The strong structure of mason-work is called the *revetment*.) The *main ditch* (*h*) is usually about 12 feet deep, and is often from 100 to 180 feet wide, though usually its width is from 13 to 18 feet wide. The counterscarp (*j*) is the wall round the outside of the ditch. The covered way (*k*) is a space of about 30 feet extending round the counterscarp, enclosed or covered from fire by a parapet. The glacis (*m*), with a banquette (*l*), is the sloping space beyond the covered way. The slope of the glacis brings the troops of the enemy within direct fire of the cannon and musketry from the parapet. The enceinte, consisting of the ditch and rampart, with its subdivisions of parapet, banquette, and terreplein, runs completely round the fortress whatever be its shape, and presents the same profile of glacis, covered way, ditch, rampart, parapet, and terreplein on all sides of it. Where water can readily be procured the ditch is flooded, and its depth of 12 feet obliges the enemy to construct rafts to cross it, and thus delays the assault at the very moment when the defenders are delivering their most destructive fire. The defensive works of a fortress are not all on the interior side of the ditch. There are *outworks* placed outside the ditch but within the glacis. The chief outwork in either of the systems of F. above mentioned is the *ravelin*, a large *Redan* (q. v.), which is useful as affording an advanced position for artillery to flank the glacis and enfilade the enemy's trenches. It is defended by ditches, which in the bastioned system are flanked by the guns of the bastions, and in the polygonal system by low casemated batteries in flanks connected with the ravelins themselves. *Advanced works* are open works beyond the glacis, under the protection of the guns of the enceinte, and the use of which is to protect ground unprotected by the guns of the fortress. *Retrenchments* are works *within works*, so that when the outer lines are carried, the defence may still be maintained by the inner lines. In the bastioned system, retrenchments are of frequent occurrence, especially within the bastions of the enceinte and in the ravelins, portions of the faces of which are isolated by a small ditch and parapet called a *coupure*. *Casemates* are arched chambers, which are bombproof under all ordinary circumstances. Magazines are always casemated. In a gun casemate the embrasure is made in the end wall of the casemate. In the Spithead Forts, Portsmouth, these end walls of casemates are constructed of iron. *Caponieres*, in the polygonal system, are large casemated stone structures built within the ditch, the purpose of which is to defend the ditches of polygonal fortifications. In German enceintes, the caponieres are detached from the escarps, are built in two stories, and are situated in the middle of each long *face* or *side* of the angle. In England they are generally attached to the escarps, have only one floor, and are placed at the angles of the ditches, so as to command both faces of the work. Communication between the works and the caponieres is maintained by a tunnel, which, when it also communicates with the ditch and outworks, is called a *postern*. A novel feature in modern F. is the mortar casemate, a vaulted chamber, without a front wall, in which the mortar is secured against vertical fire, and from which its fire can be brought to bear on the enemy advancing over the glacis. Mortar casemates are placed behind the rampart of the enceinte. Unseen by the enemy, they are the means of a most destructive fire of large shells being thrown among his advancing troops. Having reached the covered way, there is nothing to obstruct an enemy's entrance into the works of a fortress except the escarp, for the counterscarp wall may readily be blown in by mining. Nor in these days does the escarp offer a very serious obstacle, for the accuracy of the curved fire of the present day, and the weight of the shells now used, enable the artillerist to strike and destroy the strongest escarp, unless the latter be well concealed below the crest of the glacis. To neutralise as far as possible the great improvements in the accuracy and range of large guns used in attack, the tendency in modern F. is to make the ditch narrower and deeper, so that the top of the escarp wall shall be 10 or 15 feet lower than the crest of the glacis. In the profile of the English forts (Fig. 1), in which a *chemin des rondes* (*f*), or path of communication, extends round the works, between the escarp and the exterior slope of the parapet, this plan has been adopted. It may here be stated, that in *counter-arched revetments* the pressure or lateral thrust of the earth of the rampart falls upon the arches, and not upon the actual wall of the revetment. The arches are arranged usually in two tiers, and the space they afford is sometimes converted into loopholed galleries for musketry-fire through the escarp. These galleries, known as escarp or counterscarp galleries, are utilised in English and German fortresses to flank the caponieres, and thus aid in defending the ditch. In the bastioned system, bastions are connected by a curtain, in front of which is an outwork called a *tenaille*, with a parapet for the musketry defence of the ditch. The tenaille also acts as a counter-guard, and to protect the postern and escarps of the curtain and flanks from being breached. The main differences between the bastioned and polygonal systems of F. having already been adverted to, it

remains to describe Fig. 2, which exhibits the arrangement of works on a front of the German polygonal system, merely pre-

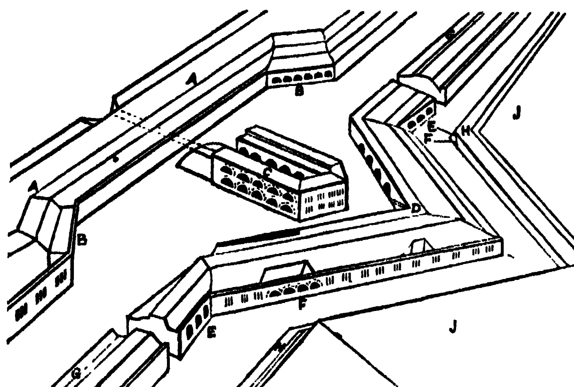

Fig. 2.—Arrangement of Works in a Front of the German Polygonal System.

mising that the great fortified works of England are constructed on similar, if not identical, principles. The figure given represents a portion of the enceinte which surrounds the work (if it be circular), and the profile of which is the same on all sides of the polygon. Beginning from the *interior* of the F., A A is the 'body of the place,' or the space enclosed by the enceinte; B B are casemated flanks in the *escarp of the rampart*, the purpose of which is to defend the ditch of the caponiere; C is a casemated caponiere, provided with two tiers of five guns, and built in the middle of the main ditch, which it commands to right and left; D is a ravelin with a ditch in front defended by the casemated flanks E E; F F are casemates in the ravelin to defend the ditch in front of the counter-guards G G; H H is the covered way, and J J the glacis.

The original works of Vauban were arranged, as to dimensions, &c., to be in harmony with the range, weight, &c., of the fire-arms of 1650, and are now obsolete. But apart from the matter of dimensions or relative proportion, the general arrangement of the fortified works of which he was the designer is still retained throughout France, and forms the basis of all the modern French systems, as exemplified in the fortifications of Paris, Metz, Lille, &c. One of the chief disadvantages of the Vauban or bastioned system, still prevalent in France, is the liability of the works to be swept by Enfilade (q. v.) or reverse fire. In the Franco-Prussian war, Forts Issy and Vanvers in Paris, and a number of the bastions of the Paris enceinte, were thus swept by the enemy's cannon, and the great number of *traverses* or covering parapets which the French found it necessary to erect along the lines of and at right angles to their covered ways and terrepleins, so as to afford protection against enfilade fire, is sufficient evidence to prove that, to this extent, they were forced to acknowledge the defect of their system. Perhaps the most complete and most interesting permanent works of modern Europe are the magnificent new fortifications of Antwerp constructed by General Brialmont. They consist of a most formidable and extensive enceinte, strengthened by a series of detached forts along the line at a distance from each other of about 2000 yards. A similar arrangement of defences—a continuous enceinte and a cordon of forts—may be seen at Paris, Metz, Lyon, Cologne, Coblentz, Mayence, &c., but Antwerp is *sui generis*, from the circumstance that in the construction and arrangement of its works the principles and details of the polygonal system have been applied and utilised with the greatest possible success.

Field Fortification.—The object of field as of permanent works is to enable a smaller to resist the attack of a larger body of men. When time is afforded for their careful construction, they are found to present a profile similar to that presented by permanent works, viz., a sheltering rampart, with parapet, ditch, and glacis. Field-works are of two kinds—open and closed. The simplest *open work* is a straight line, useful to close a gorge or defend an isthmus, but in ordinary ground liable to be destroyed by enfilade. The redan or *flèche* (Fr. 'arrow'), consisting of two straight lines or faces, forms what is called a *salient angle*. The line bisecting this angle is called a *capital*, and a line beween the open ends of the two lines or faces is called the *gorge*, which, being undefended, exposes the work to the liability of being taken in rear. A Russian redan was captured at Borodino by French cavalry riding in at the rear of the work by the gorge. Another defect of this field-work is that no provision is made for the defence of its ditch. Redans are commonly constructed for the defence of a bridge, defile, or any narrow passage. When flanks are added to redans at an angle of 100°, the work is vastly strengthened, as the flanks command the ditch as well as the ground in front of the salients. A *lunette* is a redan with two flanks running parallel to the *capital* or bisecting line of the two faces or lines forming the redan. A double redan is a work in which two redans are joined together, and provision thus made for the reciprocal defence of the inner ditches. *Enclosed field-works*, or such as are entirely surrounded by a parapet, are called *forts* when the ditches are flanked by the parapets; but where no flanking defence is afforded by the parapets, the work is called a *redoubt*. *Redoubts* may be of any shape, regular or irregular, provided the fire from any face of the rampart does not defend any line of ditch. Such works are readily constructed, and are defended by fewer men than forts. In redoubts, however, as in the polygonal system of F., the defence of the ditch is often provided for by placing caponieres so as to sweep it right and left, or by the construction of loopholed galleries in the counterscarp. Field-works comprise three kinds of forts—star, demi-bastioned, and bastioned forts. The bastioned fort is an elaborate work, constructed only in cases in which an important spot is to be fortified and an obstinate defence intended. Its ditch should be 12 feet deep, and its parapet 10 feet high and 16 feet thick, to resist a 16-lb. rifled gun. *Blockhouses*, usually formed of logs of wood, loopholed, and arranged vertically in the shape of a rectangle, polygon, or cross, are proof against rifle bullets, but offer no defence against artillery, and are only valuable in mountainous or thickly-wooded country, impracticable for field-guns. When built in the form of a cross, the blockhouse permits of a flank defence. In the Turko-Servian war (1876), field-works of this description were eminently serviceable. *Fortified lines* are either continued or interrupted by intervals. *Continued lines* are a connected line of field-works, the purpose of which is to enclose a front or connect isolated forts by a continuous parapet. They are now seldom used, from the circumstance that a parapet broken by salient and re-entering angles requires more men for its defence than are required for an ordinary line of battle, and that when once broken by the enemy, the lines may be regarded as lost. *Redan lines*, designed by Vauban, consist of a series of redans, the salients of which are 240 yards apart, and the inner faces connected by curtains. *Indented* or *crémaillère lines* consist of a series of alternate long and short faces, forming salient and re-entering angles of 90°. The defects of this trace are that the fire from the short faces is ineffective until the enemy arrives at the counterscarp of the line, and that they are exposed to enfilade fire. *Bastioned lines* consist of a series of connected bastions. The salients of the bastions are 360 yards apart, the perpendiculars are not more than 45 yards. In this trace the faces are much exposed to enfilade. *Lines with intervals* have, for almost all purposes, superseded continued lines, (1) because, as there is less extent of parapet to defend, they do not drain the garrison to an equal extent; (2) because, when one part of the line is forced, the whole does not fall; and (3) because the defending force can readily advance to the attack between the intervals. *Têtes-de-pont* or *bridge-heads* are bastioned works thrown up to cover the advance or retreat of an army across a river.

Obstacles.—In field F., the parapet is practically the only actual defensive work, and is usually constructed in haste, and often—in cases in which an earthen rampart cannot be thrown up—of materials which afford only insufficient cover. During the American civil war, a favourite form of parapet was constructed by cutting down trees and of these raising a rude breast-work. All such parapets, however, may be readily taken by assault, unless the approach to them (the glacis) is rendered difficult by what are termed obstacles. The purposes of obstacles are to impede the advance of the enemy at those points upon which the defenders can pour their most destructive fire. Obstacles may be of endless variety, dependent upon the ingenuity and resources of the commander; but 'good' obstacles must be placed well within the defenders' fire, must be sheltered from the artillery fire of the enemy, must afford no cover to the

assailants, and must be so constructed as not to be easily removed or destroyed. The following are the obstacles most commonly used in field F:—The *trou-de-loup* ('wolf-hole'), a pit of the form of an inverted cone, from 6 to 10 feet deep, 6 feet diameter at the surface, and 1 foot wide at the bottom, into which a pointed stake is driven—a contrivance which, peculiarly successful in disabling cavalry, was used with effect at Bannockburn, and is still held in esteem; *pickets* or pointed stakes, one or two inches broad, and three feet long, driven firmly into the ground close together, also effective against cavalry, and when planted on the brow of a parapet (above the escarp), cause much trouble to escaladers; *crow's feet*, which fall so that they may always present an upward-pointing iron spike,—another contrivance *pour encourager* the enemy's cavalry; *Abattis* (q. v.); *entanglements*, young trees or brushwood picketed down to the ground; *Chevaux-de-frise* (q. v.); and fougasses, small mines filled with stones or shells, charged with gunpowder, and fired either by a hose or by electricity. See *Traité de Fortification Polygonale*, and kindred works, by General Brialmont, Belgian staff; *Fortification*, by Colonel O'Brian, Sandhurst; and *Field Fortification*, by Major W. W. Knollys, F.R.G.S. (Strahan, Lond. 1875).

Fortiguerr'a, Niccolo, an Italian churchman and poet, attached as chamberlain to the household of Pope Clement XI., was born at Pistoia, November 7th, 1674, and died at Rome, February 7, 1735. His fame rests chiefly on his light epic poem *Ricciardetto* (first published at Venice in 1738), abounding in comic incident and in satire on the morals of the clergy.

Fort'-Major, an officer acting under the governor of a fortress, and whose duty it chiefly is to inspect the defences and see that they are kept in repair. If under the rank of captain, the F.-M. takes rank as junior captain. Any field-officer appointed F.-M. must first resign his regimental appointment. The number of fort-majors in 1876 77 was five.

Fortrose', or **Fortross'**, a royal burgh and seaport in Ross-shire, on the W. side of the Moray Firth, 10 miles N.N.E. of Inverness, and opposite Fort George, with which it has communication by ferry. It was formerly a centre of culture in the N., and had a cathedral and bishop's palace, the stones of which were taken by Cromwell to build a fortress at Inverness. There is still some trade in grain, pork, eggs, &c. F., along with Inverness, Forres, and Nairn, sends one member to Parliament. (Pop. (1871) 911.

Fort Royal' (properly Fort-de-France), fortress, seaport, and capital of the island of Martinique (French) in the West Indies. Its bay of the same name is said to form the best port in the Antilles. There are grand promenades, some fine edifices, and 12,000 inhabitants.

Fort St. Da'vid, formerly a maritime fortress of India, in the province of Madras, 3 miles N. of Cuddalore. It was a strong position during the contests of the French and English, and was dismantled by the latter about 1760.

Fort St. George, the first fortified settlement of the British on the mainland of India, erected in 1639, and the nucleus of the present city of Madras (q. v.). It was captured by the French in 1744.

Fort Sumt'er, a celebrated stronghold of the Confederates during the War of Secession in S. Carolina, U.S., on the S. side of the entrance to Charleston inner harbour, and 3 miles from the city. It was built in 1829, and at the time of secession it mounted seventy-eight guns, and was held by a small body of troops under Major R. Anderson. Occupying a commanding position in the harbour of Charleston, it early became the centre of interest. The civil war was begun here by the Confederate batteries of General Beauregard on the 12th of April 1861, and the fort was surrendered on the following day. It was held undisturbedly for two years, repulsed a force of nine Northern ironclads, August 17, 1863, was partly demolished by the land batteries, but was not evacuated till the final surrender of Charleston, February 18, 1865. It is now being rebuilt.

Fortu'na, among the Greeks **Tyche**, was the goddess of chance or luck. She was extensively worshipped in Greece and Italy, and was held in special honour at Rome. The Romans applied to her numerous epithets, such as *publica, privata, muliebris, conservatrix, regina*, indicative of the circumstances under which, and the persons to whom, she showed favour. F. was represented with a rudder, an emblem of her guiding power, and with a globe, to express her mutability.

For'tunate Is'lands. See CANARIES.

Fortuna'tus, the hero of an old popular story, who after undergoing great sufferings, obtains a wishing cap and exhaustless purse of gold, which eventually ruin F. and his sons. The story is of German origin, and has been recast in various forms in most of the languages of Europe. Its author is unknown, but F. seems at first to have been identical with Fortunio, another character in popular tales. The first printed edition of the story appeared at Augsburg in 1509. A Danish version was published at Copenhagen in 1664, a French at Rouen in 1670, an Italian at Naples in 1676, an Icelandic about 1690, and a Swedish in 1694, and a Dutch version at Amsterdam in 1796. The tale was dramatised in Hans Sachs' *Der F. mit dem Wunschseckel* (1553), and in Dekker's *Pleasant Comedie of Old F.* (1600). The tale is related poetically in Tieck's *Phantasus* (Berl. 1816), and the exhaustless purse reappears in Chamisso's story of *Peter Schlemil*, who sold his shadow for it. See Grässe's *Die Sagenkreise des Mittelalters* (Dresd. and Leips. 1842).

For'tune, Robert, a Scottish botanist, was born in Berwickshire, 1813, and was engaged at the Botanical Gardens of Edinburgh, and later at those of Chiswick. In 1842 he was sent by the Botanical Society of London to N. China, and the result of his visit appears in *Three Years' Wanderings in China* (1847). He spent other three years in China in the interest of the East India Company, and produced his *Two Visits to the Tea Countries of China* in 1851. This was followed by his *Residence among the Chinese Islands on the Coasts and at Sea, being the Third Visit*, 1853–56. In 1859 F. collected in China for the United States Government the seeds of the tea-shrub and other plants. His latest work, entitled *Yedo and Pekin* (1863), treats of the natural products and agriculture of Japan and China.

For'tune-Telling. Any one obtaining money or goods under pretext of foretelling is punishable, as so doing under pretence. Any one going about the country pretending to foretell is punishable as a 'rogue and vagabond' under the Vagrant Act. See BEGGARS, LAW OF ENGLAND RELATIVE TO.

Fortu'ny, Mariano, a modern Spanish painter, was born of poor parents at Reus, near Barcelona, 11th June 1839. His first experience in art was gained by assisting his grandfather, a showman, to paint wax figures. Later he studied at Madrid, and made two journeys through Morocco during the Spanish war, producing a vast number of oil and water-colour drawings. On his return he painted, on commission of the Spanish Government, his great picture, 'The Battle of Tetuan,' which procured for him a high reputation as a bold, original draughtsman, and a master of sunny, scintillating colour. He eventually settled at Rome, where he founded a school which sought inspiration from nature, and threw discredit on the 'Masters.' His splendid studio latterly became one of the public sights on account of its rare collection of enamels, ceramics, tapestries, &c. He died 21st November 1874. Among his best-known works are 'The Beach at Portici' (sold for £3952), 'The Siesta,' 'Academicians of Arcadia,' 'Marriage in the Cathedral of Madrid,' 'Snake-charmers,' and 'Madrid Procession Caught in the Rain.' He mainly held to Southern or Oriental *genre* painting. 'Le joli F.' was a perverted genius, cynical and frivolous, whose theatrical subjects lack the genuine feeling of humanity, and whose execution is always more or less feverish and flashy. He was influenced banefully by the artistic necromancy of his brother-in-law, Madrazo, and fell under the weird spell of Gérôme. The criticism of Théophile Gautier greatly helped to raise to a fabulous height the price of F.'s pictures. The unfinished works alone left at his death brought over £16,000. See *F., sa Vie, son Œuvre, sa Correspondance*, by Baron Davillier (Par. 1875).

Fort Wayne, a city of Indiana, U.S., situated at the point where the St. Joseph and St. Mary form the Maumee river, 94 miles S.W. of Lake Erie. It is a great railway centre, having the workshops of the Pittsburg, Fort Wayne, and Chicago Railways. The Wabash and Erie Canal passes through it. F. has manufactures of machinery, several newspapers, and numerous schools. The city derives its name from General Wayne, who built a fort here in 1794. Pop. (1870) 17,718.

Fort Will'iam (Gael. *Inbher Lochaidh*, 'the mouth of the dark river'), a burgh and fort in the county of Inverness, at the S. end of the Caledonian Canal, 63 miles from Inverness. The fort was first built by General Monk, rebuilt by General Mackay in 1689, and called Fort William in honour of King William. It is an irregular work, but withstood a siege by Prince Charlie's forces in 1745. It contained accommodation for 100 men. Like Fort Augustus, it has been sold by the Government, and is now occupied as private dwelling-houses. The burgh of F. W. (under the Lindsay Act), originally called Mary Burgh, afterwards Gordon's Burgh, contains a pop. of 1200, a public school, three banks, and four churches. Lying at the foot of Ben Nevis, it is very much frequented by summer tourists.

Fort William, the citadel of Calcuttá (q. v.). The original fortification was erected in 1696, but was abandoned after the sack of the city by the Nawab Seraj-ud Dowlah; the present building dates from 1773.

Fo'rum (akin to *foris* and *foras*, hence 'that which is out of doors') meant originally a clear open space, and was applied specially to the central area in towns which in ancient times served as a market-place, and also as a place for the discussion of public affairs and the administration of justice. At Rome the F. was about 224 yards in length, and about 68 yards at its greatest breadth, stretching between the Capitoline and Palatine hills, and surrounded by spacious porticoes and the shops of bankers. It consisted of two parts, the Comitium, and the Lower F., occupying respectively one-fourth and three-fourths of the area. The Comitium was so named from having been the place of meeting of the Comitia Curiata, and contained the tribunal from which the prætor of the city administered justice, and the rostra, a platform from which public speakers addressed the people, and which was so called because it had been adorned with the *beaks* of ships won from the Antiates. In the Lower F. all general business was transacted, and the Comitia Tributa met. The famous Sacra Via was the boundary of the F. on the E. and N., entering near the temple of Vesta, and leaving at the Arch of Severus. Of the additional *fora judicialia*, erected by the emperors, the most important were the F. Julium and the F. Augustum, the works of Julius Cæsar and Augustus. There were numerous *fora venalia* in Rome, as the *F. boarium*, or cattle-market; the *F. olitorium*, or vegetable market; the *F. cupedinis*, or market for dainties, &c. F. was also the name of many market and assize towns, as F. Appii, F. Aurelium, &c.

Fosca'ri, Frances'co, a doge of Venice, familiar to English readers from Byron's tragedy. Born about 1372, he was doge from 1423 till 1457. Though during his long administration Venice was prosperous at home, and successful in the almost incessant wars undertaken by her energetic doge, the animosity of his enemies triumphed in compelling F. summarily and ignominiously to resign office in 1423. He had already lost three sons in battle, and had seen the fourth tortured and banished as a traitor. He was unable to survive the crowning calamity of 1423, and died immediately after his resignation.

Fos'colo, Niccolo Ugo, an Italian patriot, poet, and man of letters, born at Zante, 26th January 1777, was educated at Venice and the university of Padua. His first tragedy, *Tieste*, was performed with success at Venice in 1797. After Venice had become an Austrian town, F., still hoping great things for Italy from the soldiers of the republic, took service as an officer in the Lombard Legion at Milan, then capital of the Cisalpine Republic. He spent several years with the French army. F.'s first romance, *Ultime Lettere di Jacopo Ortis*, had appeared in 1802, and secured him a European reputation. The poem *I Sepolcri* was well received; and in 1808 F. was called to the chair of rhetoric at Pavia, which he occupied till the professorship was suppressed. The tragedies *Ajace* and *Ricciarda* were performed in 1811 and 1813. F. forsook Italy finally after the events of 1814, and soon settled in England, where he continued to be engaged in miscellaneous literary work, illustrative of Petrarch, Dante, and other great names of Italian literature. In spite of F.'s success as author and lecturer, the exile of this high-hearted but restless and impetuous Italian was embittered by pecuniary distress. He died at Turnham Green, 14th September 1827. In 1871 his ashes were brought to Florence, amid public solemnities. The best collective edition of F.'s works is that of Le Monnier (Flor. 11 vols.). See the Biographies of F. by Pecchio (Lugano, 1833) and Carrer (Ven. 1842).

Foss'a and Fur'ca. See PIT AND GALLOWS.

Fossa'no (Lat. *Fons Sanus*, 'the healing fount'), a walled town of N. Italy, province of Cuneo, on the Stura, an affluent of the Po, and 32 miles S. of Turin by railway. It is the seat of a bishop (since 1580), and has a cathedral of San Giovanni, a castle of the 14th c., an academy of science and art, a veterinary college, and a theatre. F. has paper, silk, and leather industries, and a trade in corn, hemp, and cattle. Pop. 7279. F. was an important fortress in the 13th and 14th centuries. It was stormed by the French in 1796, and was taken by the Austrians, 18th September 1799.

Foss Dyke. See CANAL.

Fosse, or **Foss** (Lat. *fossa*, from *fodio*, 'I dig'), is the dry or wet ditch immediately surrounding the rampart of a fortification.

Foss'il (Lat. *fossilis*, from *fodere*, 'to dig'), originally anything dug out of the earth, but now limited to the remains of plants and animals found imbedded in the rocks which form the earth's crust. These organic remains are found in all states of preservation, and are probably due to the replacement of the gradually-decaying organic matter by mineral products. Each stratum has its distinctive fossils or groups of fossils, which are consequently of the greatest value in fixing the age of the formations in which they occur. Without this aid, indeed, palæontology would have no existence, and geology would lose its most important component.

Fossil Ferns. The ferns or *Filices* are first certainly represented in a fossil state in the Devonian and Old Red Sandstone rocks. The Devonian F. F. present a close resemblance to the more luxuriant vegetation which prevailed in the succeeding Carboniferous epoch. The genera *Cyclopteris*, *Neuropteris*, and *Phenopteris* include smaller species, whilst trunks of tree-ferns are also found in Devonian strata, and are referred to the genera *Caulopteris*, *Protopteris*, &c. The former genus also occurs in Carboniferous strata, along with *Palæopteris* and other typical forms. The Coal period is very rich in smaller F. F. belonging to the genera already mentioned as occurring in the Devonian, and in addition to the genera *Pecopteris* (*Alethopteris*), *Odontopteris*, *Hymenophyllites*, &c. In the Permian rocks F. F. are abundant, but resemble those of the Coal period. Many Carboniferous genera also occur in the Trias, *Neuropteris elegans* being a characteristic Secondary form. In Tertiary strata F. F. are comparatively few in number, and are not represented in the profusion characteristic of the earlier formations.

Fossilif'erous Rocks, a comprehensive term in geology, embracing all formations which contain organic remains. It is nearly synonymous with *Aqueous Rocks* (q. v.), though not unfrequently fossils are found imbedded in volcanic tuff and similar fragmental rocks.

Fossombro'ne (the Roman *Forum Sempronii*), a town and bishop's see in Central Italy, province of Pesaro-Urbino, in the valley of the Metauro, and on the *Via Flaminia*, 16 miles W.S.W. of Pesaro. It has an old castle, and a cathedral, in which are many ancient inscriptions, besides the remains of a Roman theatre and bridge. The Metauro is here spanned by a modern bridge. F. produces the *Seta della Marca*, celebrated as the finest silk in Europe. Pop. 8464. Near F. Hasdrubal was defeated and slain by the Romans in 207 B.C.

Fos'ter, Birket, an English artist, was born at North Shields in 1812. He was educated at Hitchin, Herts, and after practising wood-engraving for some time with Landells, became a draughtsman, in which capacity he early showed an aptitude for the sympathetic treatment of rich pastoral and river landscape. His illustrations of the poetical works of Goldsmith and Scott, of Beattie's *Minstrel*, of *Evangeline*, &c., are artistic gems, crisp yet fluent in drawing, and in chiaroscuro singularly brilliant and true. Of late years F. has won a high reputation for water-colouring, but his lush bosky dells and bright sunny glades leave an impression more of airy daintiness than of great artistic strength or study. He was elected a member of the Water Colour Society in 1860.

Foster, John, an eminent English essayist, was born in Halifax, Yorkshire, September 17, 1770. For a brief period he was a

weaver, but studied for the Baptist ministry at the Bristol College, and preached at Newcastle-upon-Tyne, Dublin, Downend, and Frome; but although his preaching was universally admitted to be able, it was not successful, and he gave himself up finally to literature. His great work is *Essays, in a Series of Letters*, published in 1805, when he was at Frome, and which have been much admired for their powerful if somewhat rugged thinking, and occasional imaginative outbursts. Marrying in 1808, he retired to lead a life devoted to literature and study at Bourton-on-the-Water, in Gloucestershire, preaching only at intervals. His chief work for eighteen years was writing papers for the *Eclectic Review*, his contributions to which, 'Biographical, Literary, and Philosophical,' were published in 1840. Among his other productions, the chief are *Essay on the Evils of Popular Ignorance* (1819), occasioned by his return to Downend in 1817, which first awoke the British nation to the perfect barbarism that prevailed in certain country districts; *Lectures delivered at Broadmead Chapel, Bristol* (1844 and 1847); and *Introductory Essay to Doddridge's Rise and Progress* (1825). F. died at Stapleton, near Bristol, October 15, 1843. *The Life and Correspondence of F.*, edited by J. E. Ryland, was published in 1846 (new ed. 1852).

Fou'cault, Jean Bernard Léon, a French savant, was born at Paris, September 18, 1819. Though educated as a physician, he devoted his life to experimental research in the physical sciences, and had charge of the scientific section of the *Journal des Débats* from 1845 till his death, which took place at Paris, February 13, 1868. He is widely known for the calculation of the velocity of light by means of a revolving mirror, and the establishing by direct comparison of the velocities of light in air and water the undulatory theory over the emission theory; for his invention of the Gyroscope (q. v.), and the application of it, as well as of the simple pendulum, to render the diurnal rotation of the earth evident to the bodily eye; and for his electric light apparatus, with the electro-magnetic regulator. F.'s memoirs are published in the *Comptes Rendus*, and some popular scientific treatises appear in the *Bibliothèque d'Instruction Populaire*.

Fou'ché, Joseph, born near Nantes in 1763, first appeared in public life in 1792 as member of the National Convention for Loire-Inférieure. Though a friend of Condorcet and Vergniaud, he showed much 'patriotic ferocity' in voting the king's death, in carrying out the 'Law of Suspects' in the W., and in suppressing with Chaumette the Catholic religion. At Lyon he and Collot d'Herbois perpetrated the judicial murders of which he afterwards ignobly tried to throw the blame on his enemy Robespierre. He was rewarded by the president's chair in the Jacobin Club. By lying and treachery, he survived the Reign of Terror, after which he curried favour with Director Barras by the betrayal of Babeuf's conspiracy. In the Ministry of Police, which he entered in 1799, he found the congenial task of suppressing the Jacobins, whom he had once led. The consuls being established, F. adopted milder measures, especially with regard to royalists, but his administration was disgraced by embezzlement on a grand scale. In 1802 F. was dismissed, the Ministry of Police being suppressed. The office and the man were restored under the Empire in 1804. Meantime F. resisted the murder of D'Enghien and saved the life of Moreau. To the former he applied the famous words—'It is worse than a crime; it is a blunder.' For several years F.'s administration of internal affairs was able, moderate, and popular. In 1809 he was made Duc d'Otrante; and was so popular that Napoleon became suspicious. In 1810 F. was replaced by Savary. He never recovered Napoleon's confidence, but was offered the Ministry of Police by Louis XVIII. in 1814. He resumed office during the Hundred Days, all the while maintaining friendly secret relations with leading royalists. In the Declaration of 1815 he unsuccessfully tried to obtain a recognition of the sovereignty of the people. After Waterloo F. was a member of the Provisional Government of Five, and arranged with De Vitrolles and Talleyrand the entry of the Bourbons. Once more Minister of Police, he exerted himself to reduce the list of proscriptions from 3000 to 57. Among these 57, however, were many of his old companions. This assumed moderation enraged the royalists, and F. was banished as a regicide. He died at Trieste, 25th December 1820. As regards his moral character, we may say with Robespierre—'He was a miserable impostor.' See *Mémoires de Fouché, Duc d'Otrante* (2 vols. Par. 1824), not authentic, but containing a good deal of credible matter; and *Vie de Fouché, depuis son Entrée à la Convention jusqu'à sa Mort* (Par. 1821).

Fougères', an old town in the department of Ille-et-Vilaine, France, at the confluence of the Nançon and Conesnon, 35 miles N.E. of Rennes by railway. It is overlooked by a ruined castle of the 12th c., has many quaint arcades, and is famous for its scarlet dye, the delicate tints of which are ascribed to the Nançon waters. Pop. 9805.

Fou'la, an outlying island of the Shetland group, 32 miles W. of Lerwick. It is an almost inaccessible sandstone and granitic mass, the haunt of myriads of sea-fowl, some 3 miles long, rising, in parts precipitously, 1285 feet above the sea. Pop. 250, chiefly engaged in fishing. F., which may be seen from Orkney, is supposed to be the ancient *Ultima Thule*. It is surrounded by dangerous rocks.

Fould, Achille, a French statesman, born at Paris, November 17, 1800. He was the son of a rich Jewish planter, and after travelling in Italy and the East, was returned to the Chamber of Deputies in 1842. He was a member of the Constituent Assembly in 1848, and of the Legislative Body in 1849. Under the presidency of Louis Napoleon he was four times Minister of Finances. In this post he showed great ability and disinterestedness, and though he repeatedly resigned from disapproval of Louis Napoleon's conduct, he was, after the *coup-d'état* of 1851, appointed a senator and minister of state. In 1852 he was made Commander of the Legion of Honour, and from 1861 to 1867 was again Minister of Finance. F. died at Tarbes, October 5, 1867.

Foul'is, Robert and Andrew, two celebrated Glasgow printers, born, the one April 20, 1707, the other, November 23, 1712. Robert was originally a barber with a good business, but under the advice of Dr. Francis Hutcheson, Professor of Moral Philosophy in Glasgow University, whose class he had attended, became a bookseller. The first work that brought him into reputation was an edition in Greek of *Demetrius Phalereus on Elocution* (1742). Next year he was appointed printer to the University, and soon after took into partnership his brother Andrew. During the next thirty years there followed a succession of classical reprints—Latin, Greek, English—among which may be mentioned Horace, Cicero, Homer, Herodotus, Milton, Pope, and Gray. Some of these were models of accuracy and elegance. Andrew died in 1775; Robert, in 1776. The sons of the latter maintained for some time the reputation of the firm.

Founda'tion (from the Lat. *fundus*, 'a bottom or basis'), a word applied both to the lowest part of any building or structure, and to the ground upon which it rests. The walls of a building are increased in thickness at the bottom—stepwise—in order to distribute the pressure due to the superincumbent masonry over a considerable area. Where the ground below is rock, no further preparation is needed than dressing its surface approximately level, or into a number of horizontal beds at different levels, if the surface slopes greatly. In ordinary cases, however, foundations have to be made upon material which is not only soft in itself, but which is liable to be rendered softer by the permeation of water. In these circumstances it is usual to provide a hard and impermeable base for the masonry or brickwork, and at the same time to extend the area over which the pressure acts, by putting down a layer of concrete of a thickness and breadth proportioned to the weight of the building, and the nature of the soil underneath. *Submerged* foundations, such as those for bridges, piers, &c., frequently present great difficulties to the engineer.

Foun'der, a name given to an inflammation of acute type of the laminar structures of the horse's foot, resulting usually from over-exertion. Occasionally the affection may appear as the result of derangement of the digestive system. The fore-feet are those most generally affected, but the disease is sometimes found in both fore and hind feet. The symptoms consist in heat and swelling of the feet, and in the inability of the horse to stand upon the affected feet. The treatment must first be directed to the removal of the inflammatory symptoms by antiphlogistic remedies. The shoes are to be removed and the hoof pared. Bleeding may be indicated, and the feet must be poulticed with bran-bags. The bowels must be freely evacuated, and if pus forms in the foot, it must have free vent given

to it by incisions. Mild blisters may be afterwards required to reduce swelling.

Found'ling Hos'pitals are institutions for the nurture of children abandoned by their parents. It has been a much-mooted question whether or not the laws of political economy sanction the endowment of F. H.; the argument of the opponents of these institutions being that they promote sensual immorality, the parents being relieved of the charge of maintaining the child resulting from it. If it were the rule of the institution to receive no child unless deserted by its parents, this argument would have no more force against the maintenance of F. H. than it has against the present law of England, which obliges a *parish* to maintain a deserted child. It may be doubtful whether the law of political economy carried out in full rigour would sanction any general system for the keeping alive of deserted children; because there can be no doubt that the existence of such a system does promote sexual immorality for the reason above stated. But the laws of political economy apply only to the *wealth* of nations, and human benevolence and moral culture frequently require a mitigation of these. And they do require it regarding the matter in question. We could not see helpless children dying of hunger. We think, therefore, that under wise management F. H. are, at all events, harmless institutions. They simply relieve an individual, a parish, or a state of a pecuniary burden. The F. H. of London was established by Captain Coram in 1739 as 'an hospital for the exposed and deserted children.'

Foun'dry (from the verb 'to found,' Lat. *fundare*, 'to flow out'), a place where metal in the shape of 'pig' or ingot is cast into the forms required in construction or the arts. In the common iron F., the metal (pigs broken into pieces) is melted in a Cupola (q. v.) furnace with coke as fuel, and then run into large buckets or 'ladles,' which are slung from cranes, and so can be easily and quickly moved from the furnace to any part of the F. The sand or loam moulds into which it is then poured are made as follows:—A wooden pattern is prepared, having externally exactly the form of the required object, but having projections or 'prints' on it instead of holes wherever that object has openings. If the object be hollow, a box is then made, called a 'core-box,' having *internally* exactly the same shape as the interior of the required object, plus the 'prints' upon the pattern just alluded to. A mould is then made from the pattern in soft sand or loam (the *inside* of the mould having the same form as the *outside* of the object), and a 'core' is made of the same materials by means of the core-box (the *outside* of the core having the same form as the *inside* of the object); both mould and core are dried separately, and then the latter is placed inside the former, resting in it by means of the projections corresponding to the prints. The space between the core and the mould now corresponds exactly in form and thickness with the object to be cast. The whole is built up and strengthened as may be necessary (to prevent bursting); suitable air-holes and pipes are provided; and when all is ready, the molten metal is poured in. Sufficient metal is used not merely to fill the space left between the mould and the core, but also to form a 'head' above the casting, which can afterwards be cut or broken off, and which will contain impurities and sponginess that otherwise would spoil the casting itself. After the metal has had time to cool, the mould is broken up, and the casting cleaned by the removal of the sand still adhering to it, and of burrs or conspicuous roughnesses.

The process of casting other metals than iron does not essentially differ from that described above. For brass or gun-metal an air furnace takes the place of the cupola, and steel is most often melted in crucibles. With some geometrical forms, such as the cylinder, a complete pattern is not required, and in certain cases, when a number of copies of the same object are to be cast, the pattern is made of iron instead of wood.

Foun'tain (Fr. *fontaine*, Lat. *fons*), a jet of water springing up through a natural or artificial orifice in the surface of the earth in virtue of a hydrostatic law (see ARTESIAN WELLS); or a structure, usually decorated, from which water spouts forth, either by hydrostatic pressure, by the elasticity of compressed air, or by mechanical means. In Southern Europe, nearly all the water for domestic uses is drawn from public artificial fountains. Rome and Paris are noted for the number and beauty of their fountains, and the *Grandes Eaux* of Versailles are justly admired. London is exceptionally poor in fountains; the largest, in Trafalgar Square, is supplied from an artesian well. The Crystal Palace, at Sydenham, has one of its chief attractions in its fountains, and others of great beauty may be seen in the grounds of Chatsworth in Derbyshire. The Emperor F. at Chatsworth is the most remarkable *jet-d'eau* in the world; it rises to a perpendicular height of 267 feet.

Fountain, in heraldry, is one of the *roundels* formed of six alternate wavy lines, *argent* and *azure*, or more properly barry wavy of six. The F. is represented flat (Boutell and Aveling).

Fou'qué, Friedrich Heinrich Karl, Baron de la Motte, a German romance-writer and poet, was born at Brandenburg, February 12, 1777. He served in the campaigns of 1793, 1794, 1795, and, after living in rural retirement, in the war of 1813. He spent the rest of his life at his estate of Nennhausen, at Halle, Paris, and Berlin, where he died, January 23, 1843. F. was an ardent romanticist, and wrote many tales on mediæval and Scandinavian themes, full of wild fancy, and written in a poetic style, of which the best known are *Sigurd* (Berl. 1809); the exquisite fairy-story of *Undine* (Berl. 1811; 13th ed. 1864); *Der Zauberring* (1813; new ed. 1855); *Sängers Liebe* (Tüb. 1816); and *Die zwei Brüder* (1817). He likewise wrote many poems (*Gedichte*, 5 vols. Stuttg. 1816–27), dramas, &c. He has been blamed for the fantastic unreality of his conceptions, and the shadowiness of his characters. 'His heroes,' says Heine, 'are all iron and sentiment, without body or reason.' A selection of his works, edited by himself, was issued in 12 vols. (Halle, 1844–46). Carlyle has translated F.'s beautiful tale *Aslauga's Knight*. See Carlyle's notice of F. in *Miscellaneous Essays*.

Fou'quier-Tin'ville, Antoine Quentin, public accuser in the Reign of Terror, was born at the village of Hérouelles, department of Aisne, in 1747. He was educated for the bar, but led a dissipated life, and for misconduct lost a post he held as procurator at Châtelet. F. threw himself, however, with such vehemence into the Revolution, always giving his vote for death in the Assembly, that Robespierre made him public accuser. As such his name will be infamous for all time; he called the guillotine the coining machine of the Republic, and sent to it men of all opinions that came before him—Danton, Hébert, Camille Desmoulins, and even his master, Robespierre. Finally he himself was guillotined, 7th May 1795.

Four'chambault, a town in the department of Nièvre, France, near the right bank of the Loire, 5 miles N.W. of Nevers by railway. It has large iron foundries, forges, and smelting furnaces, and an extensive manufacture of arms. The Loire is here crossed by a suspension bridge. Pop. (1872) 5835.

Four'croya, a genus of Exogenous plants, allied to the Agaves (q. v.), and belonging to the natural order *Amaryllidaceæ*. The stamens are shorter than the corolla. These plants grow in tropical climates.

Four Evan'gelists, the most easterly four of the group of twelve islands known as the Twelve Apostles, lying to the W. of Magellan's Strait.

Four'ier, François Marie Charles, born at Besançon, 7th April 1772, was the son of a wealthy merchant, lost his father's fortune during the Lyon insurrection of 1793, and served for a short time in the army. Returning to commerce, he received, it is said, his first inspiration of social reform from seeing a vessel of rice sunk at Marseille in order to raise the market price of the remainder. His article in a Lyon newspaper on the Continental triumvirate and the final struggle between France and Russia attracted some attention. In 1808 he published his *Théorie des Quatre Mouvements*, followed in 1822 by his *Traité d'Association*, republished by the disciples as *Théorie de l'Unité Universelle* (4 vols. 1841). His whole life was now given to the propagation of his doctrine, and in 1826 he fixed himself at Paris, where he died, 8th October 1837. In 1829 appeared *Le Nouveau Monde*, and in 1831 a violent attack on the 'charlatanism' of Saint Simon and Robert Owen, in which he offered to reorganise society in two months, with a profit of 300 per cent. In spite of the strange nomenclature (sometimes hieroglyphics were used) in which it was presented, F.'s theory became very popular, especially among women. The earth was

for 80,000 years to pass through certain stages of development, the normal population being 30,000,000,000, all of whom should be seven feet high, and live for 144 years. The spirit, as well as the body, would become perfect. There would be 37,000,000 Homers, Newtons, Molières. Not less striking the industrial progress. One result of the universal *remboisement* would be restoration to equilibrium of the climate, and this would cause the ice at the N. Pole to melt. Each human soul lived through the 80,000 years until the golden age, but having alternately an existence within and without the material world. The unscrupulous selfishness of capitalists is constantly denounced, and F. looks forward to a time when the whole race, with one language, one coinage, and one system of weights and measures, would be employed harmoniously in one organisation of productive labour. His plan of reform was based on the transparent fallacy that psychological phenomena are amenable to the physical laws of motion. No institution—property, succession, marriage, the Church—was to be sacrificed. There are three forces, he says, in the individual—the desire for luxury, the tendency to separate in groups, the tendency to unity. On the combination of these depends the primitive group. By a gradual change of combinations the groups form a series, which finally compose the famous 'phalanx' of 1800 persons, chiefly pursuing different tasks of their own free will, on a piece of ground a square league in extent. There is what is pompously called an 'alternation of functions,' a protest against the mechanical effects of subdivided labour. The produce is partly profit on capital, partly wages for work, and partly given to talent. The scale of wages varies with the agreeable or disagreeable character of the work; but a minimum is first set aside for the subsistence of every person, whether capable of work or not. The capital may be owned in unequal shares. The phalanx would live in one building and have one store, so as to minimise the profits of distribution; but voluntary association in families would go on as before. The fundamental idea is that labour may and ought to be rendered attractive by the opportunity of free choice, and the prohibition of excess.

Fourier, Jean Baptiste Joseph, Baron, a French mathematician, was born at Auxerre, March 21, 1768, became Professor of Mathematics at the Central School of Public Works in 1794, was one of the *savans* who accompanied Napoleon to Egypt in 1798, was appointed prefect of Grenoble under the Empire, but after 1815 lived a retired life at Paris, where he died, May 16, 1830. His great work is his *Théorie de la Chaleur* (Par. 1822), a work which abounds in mathematical investigations of the highest originality, and which introduced a new epoch in the study of the laws of thermal conduction and absorption. Of his other works may be mentioned his *Discours Préliminaire*, or preface to the *Description d'Égypte*, his *Recherches Statistiques de la Ville de Paris*, and a posthumous work, *Analyse des Équations Déterminées*, published by Navier in 1831. See Arago's *Éloge de F.* (1833).

Four Lakes, a beautiful chain of lakes in a fertile part of Wisconsin, U.S. First Lake, the lowest and smallest, is 3 miles by 2, having its outlet in Catfish River. The largest, called Mendota, is 6 miles by 4. Between it and Third, or Monona, stands the state capital, Madison.

Foveaux' Strait separates the South or Middle Island of New Zealand from Stewart's Island. At its narrowest point it is 17 miles in width.

Fow'ey, or **Foy**, a seaport in the S. of Cornwall, near the mouth of the river of the same name, 28 miles W. of Plymouth, with which it is connected by railway. It carries on active pilchard-fisheries, has a good harbour, defended by three forts, and exports iron ore and 'china stone.' Pop. (1871) 7209. F. despatched 47 ships and 770 men to the siege of Calais in 1347, was partly burned by the French in 1457, and captured by Fairfax in 1646.

Fowl (Old Eng. *fugel* and *fugol;* Fris. *fugel;* Swed. *fogel;* Dut. and Ger. *vogel;* from a verb signifying 'to fly'), a name sometimes given to any bird of large size, but usually restricted to Gallinaceous or Rasorial birds domesticated by man, as the common barndoor fowls, turkeys, Guinea-fowls, &c. Such birds form a typical group of *Rasores* or 'scratchers,' are distinguished by their strong beak and claws, adapted for picking up seeds and for scratching in the ground respectively. The head is usually provided in the males with *wattles*, often brilliantly coloured and erectile. Fowls are polygamous, one male mating with several females. They form subjects of interest to the naturalist, from their susceptibility to variation under the hand of man. Their original habitat appears to have been E. Asia. The Bankiva jungle-F. (*Gallus Bankiva*) is credited with being the progenitor of all our domestic breeds. This F. is a native of Java. The male closely resembles the English gamecock. Its comb and wattles are bright red, the *hackles* or drooping feathers of the head and neck orange-red, and the upper part of the back a deep bluish black. The tail, which is long and drooping, is also bluish black glossed with green, and the breast and under parts are black. The chief breeds or varieties of fowls which may be more or less clearly traced to the Bankiva stock are:—The Cochin-China F., whose ungainly aspect is so well known. Fabulous prices were given for pure-bred Cochins on their first introduction into this country, but the breed has now somewhat deteriorated from its frequent mixture with other varieties. The game-fowls were formerly greatly cultivated for the sake of their pugilistic qualities. The Polish fowls are known by the great plume of feathers borne on the head. The Spanish breed is a particularly fine variety, possessing a large comb, and a patch of white skin destitute of feathers below the ear. The latter variety is of large size, and is in high repute amongst poultry fanciers, from the regularity with which the birds lay. The Dorking fowls are short-legged birds, and have frequently one or more supplementary toes. The bantams are fowls of small size, noted for their courageous bearing, but rarely bred save as fancy fowls. The name common F. or barndoor F. has now come to denote a large number of fowls belonging to no special breed, but representing the effects of interbreeding between the preceding well-marked varieties. The typical F. is the jungle-F. of India; but it has had less influence in the formation of the domesticated breeds than was formerly supposed. At any rate, its peculiarities are seldom, if ever, seen in domesticated fowls in the same proportion as those of the Bankiva F. The *Gallus Sonneratii* of India is a familiar example of a wild F. allied to the domestic breeds. It is of smaller size than our common F. The male is deep grey on the back and lower parts; the tail is long and arched, and coloured with purple and gold. The female wants the wattles of the male, and also his large and lustrous hackles. Other foreign species of F. are the silky F. (*G. lanatus*) of China and Japan, the frizzled F. (*G. crispus*), and the negro F. (*G. morio*). A large species is the *G. giganteus* or gigantic F. of Sumatra, and the fork-tailed F. (*G. Javanicus*) is abundant in the Javan forests.

Fowl'er's Solu'tion, or **Liq'uor Arsenica'lis**, a well-known preparation of arsenic and potassa introduced into medicine by Dr. Fowler, is used in various forms of skin-disease, and as an antiperiodic.

Fowl'ing, the name given to the killing of birds of various kinds, for the purpose of obtaining their feathers, flesh, or other products. This practice is carried on with much skill and daring, and in many different ways, in various parts of the world—*e.g.*, in the Faröe, Shetland, and Orkney Isles, Norway, Sweden, and other portions of N. Europe. The art of the fowler depended in former years much more on personal daring and prowess than in the present day. The introduction and general use of firearms have greatly aided and extended the capture of birds, although in some districts, from the nature of the birds to be caught, and from other considerations, the use of firearms is prohibited, and the pursuit of the birds is therefore attended with as much danger as before. Small birds are caught for the cage or for table by nets or snares of various kinds. But the exercise of the art of F. in its highest development can only be seen to advantage in rocky and inaccessible situations. In the northern islands, where such birds as gannets, guillemots, gulls, solan geese, and their allies are sought after and valued, not only for the sake of their feathers, but for their flesh and fat—the former serving as food, and the latter affording oil—F. is carried on by the hazardous proceeding of letting the fowler down the face of cliffs by means of a rope; and while thus slung in mid-air, he contrives to secure the eggs as well as the birds themselves. The ropes used are made of raw cowhide, and are very durable. A second rope is usually attached to the fowler for the purpose of giving signals to the persons on the top of the cliff, and for hoisting up the birds he secures. A simpler method of F. consists in securing

birds by means of nets slung on the end of poles, but even in such a case the fowlers have to be let down the cliffs often for considerable distances.

Fowls of Warren. In the Duke of Devonshire *v.* Lodge (7 B. and C. 36) it was decided that grouse are not F. of W. See FORESTS, CHASES, WARRENS, and PARKS.

Fox (Old Eng. *fox*, Dut. *vos*, Ger. *fuchs;* perhaps allied to the Old Eng. *feax*, 'hair,' and so signifying 'the hairy animal') is the name given to *Canis vulpes* or *Vulpes vulgaris*, a genus of Carnivorous *Mammalia* closely allied to the dog and the wolf, but distinguished by the elongated pupil of the eye. The ears are pointed and triangular in shape, and the tail very bushy. The dental formula is similar to that of the dog, the teeth numbering forty-two, and consisting of six incisors, two canines, eight præmolars, and four molars in each jaw. Minor characteristics may be found in the peculiar scent or odour proceeding from the secretion of anal or tail glands, this scent often furnishing a clue to the whereabouts of the animal. The colour of the common F. is a reddish fawn, mixed with black and white hairs. The fur is coarse, and grows very thick in winter. The tail is tipped with white. The average length of the body is about 2½ feet, and the height about 12 inches. The F. lives in burrows, which he excavates in the ground, or forms by enlarging some natural opening. The burrow generally winds in a complicated manner, the entrance often being made in a circuitous fashion between the spreading roots of a large tree. The cunning and intelligence of the animal have become proverbial. When hunted, it will adopt ruses of the most extraordinary kind to throw its pursuers off the scent—*e.g.*, it will feign death when captured by man, taking advantage of a relaxed guard to escape quickly and noiselessly. A tame F., which was on friendly terms with the dogs of the household, cheated the cats of their milk by simply walking round the cats' dishes, well knowing that the cats, which exceedingly dislike the vulpine odour, would not taste the milk, which thus fell to reynard. The same animal was seen to rub himself against the dairymaid's pails so as to impregnate the milk with his odour, a due supply of the useless fluid naturally falling to his share. The female F. produces from four to six at a birth, and breeds but once annually. Varieties of the common F. are numerous. The cur F. is a small variety, and the greyhound F. has more slender limbs and a better-proportioned body than the common F. The genus *Vulpes* as now constituted includes several other well-marked species of F. The American F. (*V. fulvus*), sometimes named the red F. or cross F., varies much in colour, but is most generally of a pale yellow hue. Its name of cross F. is derived from the almost invariable presence of a blackish stripe across the shoulders. The Arctic F. (*V. lagopus*) is celebrated for the glossy nature of its white winter fur, the summer fur being grey or greyish brown. This F. occurs and is greatly hunted for its fur, in N. Europe and N. America. The soles of the feet are hairy, a peculiarity of structure which assists the animal to walk on the ice. The average length is about 3 feet. The asse or caama (*V. caama*) is a species of F. inhabiting S. Africa, the fur of which is highly valued. Other species are the *V. melanogaster* or black-bellied F. of S. Europe; the *V. Himalaicus* of the Himalaya slopes; the *V. Bengalensis* or Deccan F.; the black or coal F. (*V. alopex*) of Central Europe. The grey F. (*V. Virginianus*) of America is a commoner species than the *V. fulvus*, and exhibits all the characteristic traits of the British F.

Fox.

Law Regarding Foxes.—Foxes may be pursued and destroyed as vermin even on the property of another, the only liability being the damage done in pursuit. In England there is by common law a limited right of hunting foxes over the ground of another. In Scotland fox-hunting for sport without leave is punishable as a trespass.

Fox, Charles James, a Whig statesman and orator, born 24th January 1749, was third son of Right Honourable Henry Fox—created Lord Holland in 1763—and of Lady Georgiana Carolina, daughter of Charles Duke of Richmond, and was thus descended on one side from Charles II. He was educated at Eton and Oxford, had more Continental travel than most young men of his class, and before he had reached his majority was elected member for Midhurst, as a supporter of the Grafton Ministry. F.'s father, an old follower of Walpole, had left the Whig party, and F. began public life by supporting the absurd and unconstitutional defiance which the Commons, led by the Government, gave to the constituency of Middlesex, which had thrice returned Wilkes as member. Under Lord North's Ministry he was successively Lord of the Admiralty and Lord of the Treasury. A difference with the Premier on the Royal Marriage Bill was followed in 1774 by a serious quarrel relating to the censure of Woodfall, Horne Tooke's publisher. F. in consequence joined the Whig or Rockingham party, and came under the influence of Burke. This influence fixed and intensified his political principles, but though his reputation as an orator continued to grow, the scandal of his life (his father had recently paid £140,000 for the gaming debts of a single season) deprived him of moral leadership. He had, however, inherited the Walpole traditions of peace and civil liberty; and when in 1782 General Conway's motion for ending the American war was carried, and Rockingham, through the mediation of his rival Shelburne, constructed a cabinet, F. became Foreign Secretary. When Shelburne, the representative of Lord Chatham's policy, succeeded, F. with Keppel and Cavendish withdrew. By a junction of Lord North with the old Whig party a vote of censure was obtained (February 1783). The Portland or Coalition Ministry which followed was wrecked by the animosity of the king to F.'s East India Bill. From 1784 to 1792 F. was therefore reduced to the leadership of a powerful opposition to Pitt, and delivered great speeches on the Westminster Scrutiny, the Regency Bill, the Libel Bill, and the Russian Armament. He spoke with great effect against the abatement of impeachment by dissolution of Parliament, by which legal fiction it was attempted to defeat the trial of Warren Hastings, of which F. was a manager. In 1789 he moved the repeal of the Test and Corporation Acts, and supported Wilberforce in his holy crusade. The taking of the Bastille was hailed by him 'as the best event the world had seen.' The debate on the Quebec Government Bill (1791) severed the friendship that had so long existed between him and Burke. The Reign of Terror must have caused hesitation in the most sanguine minds; but F. from 1792 to 1797 vigorously pled the cause of peace with France. In 1795 he led the agitation against the Treason and Sedition Bills. He seconded the Grey motion for reform, called attention to the grievances of the Irish Catholics, and exposed the tyranny of crown and bench in the Scotch cases of Muir and Palmer. Though thoroughly persuaded of the advantages and necessity of party government, he retired into private life in 1797, saying that the House of Commons had ceased to discuss. His time until 1802 was occupied with literature and sport, and the beginning of his *History of James I.*, which he intended as an antidote to the brilliant misrepresentations of Hume's Charles I. After the death of Pitt in January 1806, F. again became Foreign Secretary under Granville. A further negotiation for peace, the passing of the Limited Service Bill, and a resolution to abolish the slave trade were the fruits of this short season of power. He died 13th September 1806. Opinions have varied much as to F.'s true character. Walpole describes him as first in Parliament, at Newmarket, and at the gaming-table. Pitt spoke of him as a magician. Mackintosh and Burke have confessed the splendid power of his passionate speech. Hazlitt and Bulwer Lytton accuse him of deserting Lord North through pique. He was doubtless the great champion of parliamentary freedom at a critical time, and Catherine II. did right to place his bust with those of Cicero and Demosthenes. He had the instinct of civil and religious liberty, and Villemain truly says he was the only English statesman who understood the French Revolution. His speeches were edited by Erskine (6 vols. Lond. 1815). See Lord John Russell's *Life and Times of F.* (2 vols. Lond. 1856-59), and *Memorials and Correspondence of F.* (4 vols. Lond. 1853-57).

Fox, George, the founder of the Society of Friends (q. v.), born at Drayton, in Leicestershire, in 1624, was first a shepherd and afterwards a shoemaker. About the age of nineteen he became deeply convinced that he had received a special call from

God, and began to wander through the country rapt in religious dreams. His garb was somewhat grotesque, consisting of a single garment of leather made by himself. About 1646 he resolved to give up attendance on Church ordinances, and content himself with the teaching of the 'Spirit.' Two years later he appeared as a preacher at Manchester, urging men to trust in the 'inner light,' and to cast aside as useless or pernicious the forms and ceremonics of worship. This was the burden of all his discourses. For upwards of forty years he may be said to have done nothing else than beseech men in a pathetic, wistful, and half-bewildered fashion to have faith in the 'inner light. The dogma-loving Puritans could not endure his wayward mysticism, and in spite of the fine moral simplicity and purity of his character, he and his 'people' suffered a good deal of persecution. In 1655 F. was brought to London, and had an interview with Cromwell, who recognised an honest soul under the 'leathern hull,' and dismissed him in a friendly way. In 1669 he married the widow of Judge Fell, one of his converts in Lancashire, after which he went to America, and on his return paid a visit to the N. of Germany. Before his death, 13th January 1690-91, the 'Society of Friends' had acquired considerable importance. F.'s writings, including his curious autobiographical *Journal*, were collected and published in 3 vols. 1694-1706. See also the Biographies of Marsh (Lond. 1847), Janney (Philadelphia, 1853), Watson (Lond. 1860), and Spurgeon (Lond. 1866).

Fox, sometimes **Foxe, John,** the martyrologist, was born at Boston, Lincolnshire, in 1517. Educated at Oxford, he was elected to a fellowship of Magdalen College, but having accepted the doctrines of the Reformation, was expelled from it, July 22, 1545. After some time he became a tutor, first in the family of Sir Thomas Lucy of Charlecote, and then in that of the Duchess of Richmond. In the reign of Edward VI., F. was ordained a deacon of the Reformed Church, but in that of Mary had to flee to the Continent, living for a time at Basel as a corrector of the press. Returning to England in the reign of Elizabeth he held various offices in the Church, including a prebendal stall in the cathedral of Salisbury, and would have received further preferment, had he not been suspected of holding Nonconformist opinions, a belief strengthened by his refusal to subscribe to the Thirty-Nine Articles, and his interceding with the Queen for some Anabaptists who had been condemned to death. He died in 1587. F., who in early life had written some Latin 'Moralities,' one of which, *De Christo Triumphante*, was printed at London in 1557, and who was towards the end of his career a keen ecclesiastical controversialist, is remembered chiefly for his *History of the Acts and Monuments of the Church*, popularly styled *Foxe's Book of Martyrs* (first Latin ed. Stras. 1554; 2d Latin ed. enlarged, Basel, 1559, of which the English translation of 1563 was made), which has gone through innumerable editions, and is still looked upon as one of the manuals of Protestant literature. The first idea of the work was suggested to him by Lady Jane Grey. The truth of many of its statements has been questioned by Catholic critics, who have styled it *la légende dorée de F.*

Fox, William Johnston, an orator and preacher, the son of a small farmer, was born at Uggeshall, near Wrentham, Suffolk, March 1786. He was educated for the Independent ministry, but went over to the Unitarians, and finally took an independent position as a Rationalist, preaching for some time at the South Street Chapel, Finsbury. He was one of the earliest members of the Anti-Corn-Law League, the object of which he advocated with great ability, both as a speaker and a writer. He was returned to Parliament in 1847 for Oldham, which he represented with short intervals until his death, in London, June 3, 1864. F. was a Radical in politics, a 'Theist' in religion, a clear and vigorous writer, and a singularly effective orator. His chief works are *Letters of a Norwich Weaver-Boy*, *Letters addressed chiefly to the Working Classes*—telling political pamphlets—and *Religious Ideas.* F. was a frequent contributor to the *Westminster Review* and other periodicals. An edition of his selected works was published in 1868 (12 vols.).

Fox-Bats (*Pteropidæ*), the name applied to a family and section of *Cheiroptera* (q. v.) or bats. They are so named from the resemblance of the head to that of the fox. They are Frugivorous or fruit-eating, and possess a long pointed snout. The ears are of moderate size, and destitute of appendages. Incisors and cutting canine teeth are developed in both jaws. The F.-B. feed chiefly on vegetable matters, but they also subsist on small birds and mammals. The molar teeth have blunt tuberculate crowns. The tail is short or absent. Of the F.-B. the best-known species is the Kalong bat (*Pteropus edulis*) in the Eastern Archipelago, which attains an expanse of wing from 4 to 5 feet. The F.-B. are absent from the New World.

Fox'glove. See DIGITALIS.

Fox'hound. See FOX-HUNTING.

Fox'-Hunting, a thoroughly English sport, pursued by the middle and upper classes with courage and ardour, especially in the autumnal and winter months. It demands much organisation, not only as regards the breed and quality of the dogs employed, but in the training and appointment of the men connected with the pack and with the management of the dogs in the sport. The horses employed in hunting require also a certain degree of training and breeding; the qualities which render a horse a first-rate hunter being courage, agility, and a certain fondness or disposition for the work. The management and control of the pack of foxhounds is vested in a gentleman named the *master*, the appointment being generally given to some prominent country gentleman, who is elected by the subscribers to the pack, and who holds office either for a stated number of years, or for such time as may suit his tastes and convenience. Under the master are the *huntsman* and several *whipppers-in* or *whips.* On the former devolves the duty of attending to the health of the dogs, and of seeing that they are properly housed and fed. He also directs their journey to the field, and exercises supreme control over their movements in the chase. The huntsman, in fact, is the active director of the sport, and is regarded as the leading character in the field, and as one whose directions all are expected to follow. The *whips* are so named from the fact that part of their duties consists in 'whipping' or bringing up lagging hounds to the front. But this duty—discharged in some instances by the second whipper-in—is a very subsidiary one in the office of *whip*, and this latter official may be said to be simply a qualified assistant to the huntsman himself. The dogs used in hunting the fox are named foxhounds, and 'Stonehenge' has justly remarked that 'the modern foxhound is one of the most wonderful animals in creation.' His acute scent, his wonderful sagacity in comprehending the difficulties of any position in the field, his efforts to circumvent the natural cunning of the fox, his speed and power of endurance, form traits which only require mention to be thoroughly appreciated. The breeding and training of foxhounds are tasks of no ordinary difficulty; the modern foxhound representing in itself a combination of a great variety of breeds. The average height of these dogs, in their thoroughbred state, is from 20 to 25 inches, and those forming a pack are usually selected of the same height. Their speed is sometimes very great. 'Bluecap,' a famous hound, ran over the Beacon course at Newmarket—a distance of 4 miles, 1 furlong, and 132 yards—in 8 minutes and a few seconds. The racehorse 'Flying Childers' ran the same distance in about 30 seconds less time. The country best adapted for F.-H. is that in which level and undulating ground, with a fair mixture of pasturage and plantation, are intermingled. The 'earths' or burrows of the foxes are duly 'stopped' by the *earth-stopper* or gamekeeper on the night preceding the hunt, after the foxes have left their dens on their nocturnal foraging expeditions. The foxes, shut out of their homes, usually seek refuge in thickets, and the localities of the 'stopped' earths being duly noted, the efforts of the huntsman are directed to these spots. The huntsmen and the hounds being assembled in the neighbourhood of the coverts, the dogs are 'thrown off,' and are encouraged to seek the fox in his temporary lair, the huntsman and whip following the pack. The master's duty chiefly consists in regulating the acts of the riders, in conformity with the huntsman's operations. Occasionally the riders may assist in searching the covert, and those outside watch eagerly for the first symptoms on the part of the hounds of having found or 'scented' a fox. Some old hound acts as leader, and betokens the presence of the fox or scent by a peculiar whimper. Sometimes a fox may be at once seized and *chopped* or torn to pieces, before he can escape; an incident which is of course a catastrophe so far as the sport is concerned. Sooner or later the fox leaves

or *breaks cover*, and is allowed to gain a certain distance from the hounds. The person who notices his escape then gives the *View halloa!* as the warning cry is named. The *Tallyho!* of the huntsman is then heard, and the hounds are called together by the sound of the horn, while the whips collect the stragglers. Speedily the dogs *settle* to their work, and the pack, accompanied by the riders, are soon in *full cry* after the quarry. The sport thus begun continues to increase in excitement, the chase leading the huntsmen over mile after mile of country, swiftly or slowly as the scent is good or fails. In the latter case the dogs are said to be *at fault*, the sportsmen in such a case remaining at some distance, while the huntsman endeavours to set them once more on the scent. If the scent be recovered, the chase is resumed; but if it be lost, a fresh fox is drawn. The rider first *in* at the death of the fox lashes the hounds off, and secures the head, feet or *pads*, and tail or *brush* of the fox. The midland counties of England and Scotland are the chief localities in which the sport is carried on to any great extent. Large sums of money, amounting to thousands of pounds, may be annually spent on a pack of hounds and their maintenance.

Fox River, the name of two streams in the United States, both rising in Wisconsin, the more important of which, also known as the Neenah, is connected by canal with Wisconsin river, flows into Green Bay, after a course of 150 miles, is improved by means of a system of locks and jetties, and forms the connecting link between the great lakes and the Mississippi and its tributaries. The other flows S. and S.W. into the Illinois river, provides ample water-power, and has a course of 200 miles.

Fox-Shark (*Carcharias* or *Alopias vulpes*), a species of shark, also known as the 'thresher-shark,' from the excessive development of the upper lobe of the tail, which is thus more typically *heterocercal* or unequally lobed than in other sharks. This fish occurs in the Atlantic Ocean and Mediterranean Sea, and has been frequently found off the English coasts. It attains an average length of 12 or 13 feet. Its food consists of herrings and other fishes. The colour is slaty blue above, and the same hue mottled with white prevails on the under parts. The snout is shortened and conical, and the gill-openings are small, the hinder gill-slit being placed over the pectoral fins. The teeth are flat and three-sided. The tail is used as a defensive weapon. The other names applied to this fish are *sea-fox* and *sea-ape*.

Foxtail Grass (*Alopecurus*), a genus of *Gramineæ* or grasses having a *spiked panicle* of flowers with equal *glumes*. The meadow F.-G. (*A. pratensis*) is a familiar meadow-grass, and attains a height of from 1 to 2 feet. Another species is the jointed F.-G. (*A. geniculatus*), which has its culm bent at the joints. The slender F.-G. (*A. agrestis*) grows favourably on sandy and dry soils. *A. nigricans* is a European and N. Asiatic species, which thrive in Britain.

Foy, Maximilien Sébastien, a French general and orator, was born at Ham, in Picardy, February 3, 1775. He first served in 1792 under Dumouriez, and subsequently under Moreau, Massena, and finally Napoleon himself, gaining distinction by his daring bravery. Although opposed to the ambition of Napoleon, his ability was such that he was promoted to high and important commands. He successfully defended Constantinople in 1807 against Admiral Duckworth, became brigadier-general in Portugal in 1808, fought at Salamanca in 1812, was severely wounded at Orthez in 1814, and received his fifteenth wound at Waterloo. Retiring from military life, F. was elected in 1819 member of the Chamber of Deputies for the department of Aisne, and became very popular on account of his advocacy of constitutional liberty, his eloquence, and his political and economical knowledge. His health broke down, however, and he died at Paris, November 28, 1825. In 1826 appeared two volumes of his speeches, with a biography, and in 1827 his unfinished *Histoire de la Guerre de la Péninsule*, edited by Madame F. See Vidal's *Vie Militaire et Politique du Général F.* (1826).

Foy'ers, a mountain stream in Inverness-shire, rises in the Monadhliadh, flows N. through Strath Errick, and enters Loch Ness, 10 miles N.N.E. of Fort Augustus, after a course of 15 miles. It is famed on account of the two falls near its mouth, 90 and 30 feet high respectively, the former of which is a magnificent cascade, romantically hidden in a wild gorge.

Foyle, Lough, an extensive arm of the Atlantic in the N. of Ireland, separates Donegal from Derry, is of triangular shape, and has a length from N.E. to S.W. of 16 miles. It contracts at its mouth to 1 mile, is navigable to vessels of 200 tons along its W. side, but on the E. is very shallow. On the flat eastern beach was measured the base line of the Irish survey. The Irish North-Western Railway is continued from Londonderry completely round its E. shore.

Fra Angel'ico (often named *Giovanni da Fiesole*, but whose baptismal name appears to have been *Giovanni Guido Santi-Tosini*) was born at Mugello, a few miles N.E. of Florence, in 1387. In 1409 he entered the order of Predicants at the convent of Fiesole, and lived there eighteen years, during which he beautifully illuminated many of the books used in the choir, and painted a large number of frescoes and easel pictures in distemper. Invited to Florence in 1436, he there decorated the convent of San Marco and other public edifices with frescoes. About 1445 Pope Eugenius IV. called him to Rome to decorate a private chapel in the Vatican and the cathedral of Orvieto with frescoes. At the command of Niccolo V., the successor of Eugenius, and a liberal patron of the arts, F. A., leaving his works unfinished at Orvieto, repaired to Rome to decorate a chapel to be used as the Pope's private oratory. There he spent the remainder of his days, and died in 1455. He was offered the archbishopric of Florence by Niccolo, but declined it on the plea that to govern or to lead were equally incompatible with his nature. His art is distinguished by an ecstatic reverential sentiment, the truth and purity of which made his works the model for religious painters of his own and succeeding generations. Every work he began with prayer, and every original idea was welcomed as a divine inspiration. F. A. may be studied to most advantage in the convent of San Marco, Florence. Here are his 'Christ Appearing to St. Dominic,' 'The Image of St. Thomas Aquinas,' 'St. Peter the Martyr,' a 'Christ,' in which the expression of the features reaches the sublime. Here also is his greatest fresco, the 'Passion,' a work embracing twenty-three large figures, with Christ in the centre, and saints and founders of religious orders ranged below. Placed around are numerous figures and medallion portraits. All these works are in excellent preservation. Vasari has said that F. A.'s saints and angels 'must look the same in heaven.' The chapel of Niccolo V. is decorated on three sides with frescoes illustrating the lives of St. Stephen and St. Lawrence, works unrivalled in finish and in sweetness and harmony of colour, and evincing a command of light and shade which almost justifies the opinion that in chiaroscuro F. A. anticipated Correggio.

Fracasto'ro, Girola'mo, a physician and poet, distinguished for his miscellaneous learning, was born at Verona in 1483. At the age of nineteen he was Professor of Dialectic at Padua. His most famous work is a poem in three books, *Syphilis, sive de Morbo Gallico*, in excellent Latin verse, published at Verona in 1530, and frequently reprinted. Other works are *De Vini Temperatura* (Ven. 1534), *Homocentricorum* (Ven. 1535), *De Sympathia*, and *De Contagionibus* (Ven. 1546). F. died 8th August 1553. His *Opera Omnia* were published at Venice in 1555.

Frac'tion (Lat. *fractio*, 'a breaking into parts'), in arithmetic, is one or more aliquot parts or sub-multiples of unity. For instance, divide any magnitude into *eight* equal parts, and take *five* of these parts: this quantity is the F. *five-eighths*, and is written $\frac{5}{8}$, the lower number being termed the *denominator* and the upper the *numerator*. Such an expression as $\frac{11}{8}$ is termed an *improper* F., because it is greater than unity, being really *one* and $\frac{3}{8}$. It is immaterial whether we regard $\frac{5}{8}$ as being *five* of those parts *eight* of which make up unity, or as being the eighth part of five units. It is this latter conception which is chiefly present to the mind in algebra, in which a F. is simply a symbol of division, $\frac{a}{b}$ being equivalent to and treated as $a \div b$. From this definition the following rules for the four fundamental operations with respect to fractions follow naturally: $\frac{a}{b}+\frac{c}{d}=\frac{ad}{bd}+\frac{bc}{bd}=\frac{ad+bc}{bd}$; $\frac{a}{b}\times\frac{c}{d}=\frac{ac}{bd}$; $\frac{a}{b}\div\frac{c}{d}=\frac{a}{b}\times\frac{d}{c}=\frac{ad}{bc}$. For the usual rules for reduction and combination, reference must be made to an elementary treatise

on algebra or arithmetic. When the denominator is a power of *ten*, the F. is called a *Decimal* F. (q. v.).

A *continued* F. is one which has in its denominator a F. which again in its denominator has a F., and so on. Such as

$$F = a + \cfrac{1}{b + \cfrac{1}{c + \cfrac{1}{d + \cfrac{1}{e + \&c.}}}}$$

or, more conveniently, $F = a + \frac{1}{b+}\frac{1}{c+}\frac{1}{d+}\frac{1}{e+}$ &c.

If the *quotients a, b, c*, &c., are finite in number, then we have a *terminating* continued F., and any ordinary F. may be expressed as such. Conversely, by breaking off at any quotient, the continued F. may be expressed as an ordinary F. If we write $a + \frac{1}{b} = B$, $a + \frac{1}{b+}\frac{1}{c} = C$, $a + \frac{1}{b+}\frac{1}{c+}\frac{1}{d} = D$, &c., *B, C, D*, &c. are termed *convergents* of the continued F., and these convergents are alternately greater and less in value than the F. Further, each convergent is nearer in value to the F. than the one immediately preceding it is, so that they may be said to oscillate from excess to defect with ever-decreasing amplitude. The theory of this branch of pure mathematics has been much studied by Wallis, Euler, Legendre, Sylvester, &c.

A *vanishing F.* is an algebraic F. which for a certain value of the variable takes the form $\frac{0}{0}$, or $\frac{\infty}{\infty}$. For instance, $\frac{x^2-1}{x-1}$ and $\frac{\log. x}{x-1}$ both become $\frac{0}{0}$, when $x = 1$. Now this shows that there is a common factor in numerator and denominator which becomes zero for the special case. In the first example this common factor is evidently $x - 1$, and the value of the F. becomes $x + 1 = 2$, when $x = 1$. The value of the second example may be found by putting $x - 1 = z$, when the expression becomes $\frac{\log. (1+z)}{z} = \frac{1}{z}\left(z - \frac{z^2}{2} + \frac{z^3}{3} - \ldots\right) = 1$ when $z = 0$, that is when $x = 1$.

Frac'ture, in mineralogy, is the surface exhibited by a crystal when broken in a direction not coinciding with the planes of cleavage. The terms *conchoidal, even, uneven, hackly, splintery*, are used to distinguish the several kinds of fractures.

Fractures are almost invariably the result of direct or indirect external violence, the former being the more serious lesion, and generally complicated with considerable mischief to the soft parts. When caused by indirect violence, the bone is broken by being snapped between a resisting medium on one side, and the weight of the body on the other. F. are predisposed to by old age, cancerous and syphilitic diseases, scurvy, fragilitas ossium, frosty weather, &c. F. are called *simple* when the bone is broken across; *impacted* when one fragment is wedged into another; *comminuted* when the bone is broken into several fragments; *compound* when the soft parts covering the broken ends of bone are torn through so that the fracture communicates with the surface of the body; *complicated* when conjoined with other circumstances which may be of more importance than the fracture itself, as injury to some important internal organ, the laceration of a principal artery, or a dislocation. In general, F. are easily detected, the most obvious symptoms being increased mobility, displacement conjoined with crepitus, and a peculiar rough feeling caused by the broken extremities grating against each other. A fractured bone is ultimately united by the deposition of new bone around, within, and lastly between the broken fragments, the material for repair being termed *callus*. The callus deposited round the fracture is called *provisional*, as it merely serves as a wrapper and support, and is afterwards in great part reabsorbed, while that deposited between the broken ends is permanently left, and is called *definitive callus*. Treatment:—Wherever the fracture may be, the broken ends of the bone must be brought into as perfect apposition as possible; appropriate appliances must be adapted to prevent the recurrence of displacement; and the constitutional condition of the patient must be properly attended to. Various appliances are in use to prevent the recurrence of displacement. Splints are generally made of wood, pasteboard, gutta percha, or iron; and the bandage with which the limb is enveloped may be converted into a splint by means of starch or dextrine, or a shell may be formed for it by plaster of Paris. A simple fracture is pretty firmly united by the sixth or eighth week, but formerly three or four months elapsed before union of compound fractures took place. When compound fractures are treated by the antiseptic process, introduced by Professor Lister of Edinburgh, union takes place almost as speedily as in the case of simple F.

Fra Diav'olo, a name better known among musical connoisseurs than among students of history, was the *soubriquet* of one Michele Pezza, an Italian adventurer, born in Calabria about 1760, and who successively became a weaver, a soldier, a monk, and a brigand. His cruelty and rapacity were almost equalled by his ingenuity and resource. When pursued, he retired to the Calabrian mountains, amid which he frequently defeated the armed forces sent against him, though these were numerically superior to his own. Ardently loyal, he warmly espoused the cause of the royal house of Naples against the French in the beginning of the century. He was, however, taken prisoner, and executed in November 1806, for an attempt to raise a rebellion against the invaders. The name has been immortalised in Auber's famous opera, though his hero is a 'Devil' of much milder disposition than the Calabrian brigand.

Frame-Bridge, a name sometimes given to a timber bridge with trussed girders similar to those now used frequently in iron bridges. See BRACES, LATTICE GIRDER, TRUSS.

Fram'lingham (*i.e.*, 'strangers' town'), a market-town of Suffolk, on the Alde, 14 miles N.N.E. of Ipswich, and 90 N.E. of London by railway. It has extensive remains of an old castle, with thirteen towers, several of which are about 60 feet high, and a gateway carved with heraldic devices. To this the Princess Mary retired when Lady Jane Grey was proclaimed queen. The church of F. is built of flint, has a fine tower 100 feet high with a peal of eight bells, and contains many illustrious tombs and monuments, including those of the Howards, Fitzroys, &c. The Albert Memorial Middle Class College, for boys, was opened in 1865. F. has some trade in corn, and is the terminus of a branch line of the Great Eastern Railway. Pop. (1871) 2569.

Franc, the current silver coin of France, introduced in 1795 to supersede the *livre tournois*. Its value is very nearly $\frac{1}{25}$ of a pound sterling, or about 9½d. The coin has also been adopted by Belgium and Switzerland, and by Italy under the name of *lira nuova*.

Francavill'a, a town in the province of Bari, S. Italy, 23 miles W. of Brindisi, is the seat of a college, and has cotton and woollen industries. The public buildings comprise three hospitals and many convents and churches. Pop. 17,600.

France (Lat. *Francia*, Ger. *Frankreich*), one of the largest and most important countries of Europe, extends from 42° 20′ to 51° 5′ N. lat., and from 8° 15′ to 4° 54′ W. long. It is bounded N. by the English Channel and the Strait of Dover; W. by the Bay of Biscay; S. by the Pyrenees and the Mediterranean Sea. The E. boundary begins in the S. with the Maritime Alps, the line running along the principal ridge from Colla Lunga to Mont Blanc. It then descends to the Lake of Geneva, and curving round the canton of Geneva follows the Jura mountains to the pass at Belfort, crossing which it keeps along the ridge of the Vosges. To the S. of the Dondon in the Lower Vosges it leaves the range, and ceasing to depend on natural features, becomes an arbitrary line, passing between Nancy and Metz, and holding a north-westerly direction, crosses the Meuse, Sambre, and Scheldt, and reaches the Straits of Dover 8 miles from Dunkirk. The country, which is of hexagonal shape, is extremely compact, its greatest extension from N. to S. being 600 miles, and from E. to W. 550, while in a diagonal direction from Finistère to Mentone it measures nearly 700 miles. The coast, which is flat and marshy in the S. along the Mediterranean, and bold and broken in the N.W., has an extreme length of 1500 miles, including Corsica. Among the promontories are the Gris-Nez, in Pas-de-Calais, the nearest point to England; Cap la Hague and Pointe de Barfleur in the N. of Manche; Pointes St. Matthieu and Raz in Finistère; and in the Mediterranean the Caps Cépet, Cicie, Couronne, &c. The coast is in part fringed with small islands, of which the chief are Corsica, now forming a department, Ushant and Belle Isle to the S. of Morbihan, Noirmoutier and Ile d'Yeu to the W. of Vendée, Ré and Oléron to the W. of Charente-Inférieure, the isles of Hyères and Lerins off the coast of Var. F. comprises

$\frac{1}{18}$th part of the area of Europe. The populations and areas of its divisions are as follows, according to the *Almanach de Gotha* for 1876 :—

Departments.	Pop. (1872).	Area in sq. miles.	Chief towns.
Ain	363,290	2258	Bourg.
Aisne	552,439	2830	Laon.

	36,102,921	204,300	

Physical Aspect.—The surface of F. is on the whole a somewhat monotonous plain, inclining gently downwards from the Alps and the Pyrenees in a north-westerly direction to the Atlantic. It is rarely marked either by grandeur or variety. The mountain ranges may be divided into (1) an outer girdle, comprising the Pyrenees in the S., and the Vosges, Jura, and Alps in the E.; (2) the range of the Cevennes (q. v.), which stretch from the Pyrenees in a line parallel with the range of Lyon, and then N. along the western side of the Rhone basin, to be continued by the Côte-d'-Or and Plateau de Langres in a direction N.E. to the Vosges; (3) the mountains of Auvergne, separating the basins of the Dordogne and Lot in the S. from that of the Loire in the N., and sending off Mont Margeride towards the Cevennes in a south-easterly line, and several low ranges, as the Hauteurs de Gatine, in a direction N.W. and parallel with the Indre and other southern affluents of the Loire; and (4) the mountains of Bretagne, which run in sinuous masses E. and W., and extend into Lower Normandy, sending a spur N.N.E. into the peninsula of Cotentin. The Alps extend for about 280 miles along the frontier, and contain the highest summits in France, as Mont Blanc in Haute Savoie (15,781 feet), Grand Pelvoux (13,440), Mont Genèvre (11,782), and Mont Viso (12,586). Many ramifications trend E. towards the Rhone, forming a wild highland region, in which are the Alps of Vallais, Faucigny, Chablais, &c. The Jura range has a sharp rocky contour, and stretches N.N.E. for 450 miles. The Vosges, to the N. of the Jura, gradually lose the Alpine character, and are noted for their vast forests of beech, fir, &c. A considerable depression (Valdieu), known as the Pass of Belfort, divides the Jura mountains from the Vosges, and forms the great eastern gateway to F. Along the N.E. boundary the country rises to the wild, broken plateau of the Ardennes (q. v.). The Pyrenees (q. v.), though inferior in height to the Alps, are wilder and gloomier, consisting of sharp conical groups and ridges, crossed by difficult passes. The Cevennes have a length of 295 miles, and are precipitous mountains, rising in the S.E. in Mont Meyen to a height of 5794 feet, and sinking gradually in the N., where they give place to the Côte-d'Or, on the slopes of which are produced some of the finest wines of France. The mountains of Auvergne are volcanic, and include the Puy de Saucy (6187), Cantal (6093), Mont Dore (6188), and Puy de Dôme (4806). The chain of the Puys extending N. is a singular series of extinct volcanoes (*chéires*), now clad with verdure, but whose craters and lava-streams are easily distinguishable. To the S. of Auvergne stretches the vast expanse of the *Causses*, calcareous plateaux deeply cut by the Lot, Tarn, Aveyron, and other streams.

Hydrography.—The three great rivers of F. flowing W., the Seine, Loire, and Garonne, have their sources in the Cevennes. The Rhone, entering F. after issuing from the Lake of Geneva, flows S. on joining its great affluent, the Saône. The rivers to the N. of the Faucilles and Plateau de Langres, the Meuse, Moselle, and Scheldt, flow through Rhenish Prussia and Belgium to the Rhine or directly to the North Sea. F. has about 200 navigable streams, which are utilised to the extent of 5500 miles. Smaller rivers with basins of their own are the Somme and Orne, the Vilaine and Charente, and the Adour. Affluents of the Seine are the Aube, Oise, Yonne, and Marne; of the Loire, the Sarthe, Loiret, Allier, Maine; of the Garonne, the Dordogne, Lot, and Tarn; of the Rhone, besides the Saône, the Durance, Isère, Ain, and Ardèche. The extensive river system has been supplemented by 100 canals, with a total length of about 3000 miles. The rivers of F. flowing S. are liable to rapid inundations. Among the lakes of F., which are few, the largest are Bourget in Savoie, 12½ miles long and 2½ broad, and Grandlieu in the Vendée. There are numerous lagoons (*étangs*) along the coasts of Gascony, Roussillon, Languedoc, and especially about the mouth of the Rhone.

Climate.—Lying mainly between the annual isotherms 50°–60° F., F. enjoys a singularly fine climate. The climate of the N. generally corresponds to that of the S. of England, but in the S. the winters are much shorter and milder, and the sky is almost invariably clear. Along the Mediterranean the mean temperature is 57°. The regions towards the Alps and the Pyrenees are exposed to wild tempests and piercing winds. In the Rhone valley the temperature is subject to sudden change, owing to the alternations of the hot blast of the sirocco from the S., and the cold impetuous mistral from the N.W. The annual fall of

rain on the W. coast is 24 inches, on the S. 23, on the N. 22. The number of rainy days on the W. coast is 152, in the interior 147, on the S. coast 66, at Paris 105.

Geology and Mineralogy.—The geology of F., like that of England, embraces almost all the stratified and non-stratified formations. The greatest area is covered by the Secondary strata, which prevail chiefly in the departments in the E. and N.E., stretching from the Mediterranean to the Moselle. In the W. also they extend from the Garonne to the mouth of the Seine, excluding Bretagne, which is mainly Silurian. The Tertiary series, next in extent to the Secondary, occurs between the Pyrenees and Garonne, and along the E. banks of the Rhone and Saône, and forms the extensive *Paris basin*. The Bretagne hills are chiefly of granitic rocks, and in Cantal and Puy-de-Dôme the rugged angular mountain masses are of volcanic origin. The coal deposits are most abundant in the central departments, in the Cevennes, and along the N.W. coast. French coal is unaccompanied by ironstone. Iron is widely distributed, and is wrought to the extent of half a million of tons yearly. Lead and silver are mined in Finistère, Isère, Puy-de-Dôme, &c.; copper in Haut-Rhin, the Rhone, and Basses-Pyrénées. In the E. the salt-mines are of great value. Besides marble and alabaster, there are also among the natural products some argentiferous galena, manganese, antimony, porcelain clay, lithographic stones, slates, &c. There are many mineral springs, of which the most frequented by invalids are in the Pyrenees at Vichy, Mont Dore, Plombières, and Bourbonne.

Botany and Agriculture.—In the number and variety of its indigenous plants F. surpasses all the other countries of Europe. Ruskin gives a verdict in favour of the trees of F. over those of all other countries for grace of stem and perfection of form in their transparent foliage, and for their beautiful modes of grouping and massing. The forest-trees occupy nearly one-eighth of the entire surface, and include the oak, beech, elm, ash, birch, &c. The largest forests are those of Compiègne, Chantilly, St. Germain, Fontainebleau, Orleans, and the Ardennes. Pines are plentiful in the Pyrenees and Landes, firs in the Jura and Vosges, larches in the Alps, cork-trees only in the basin of the Adour and in Provence. On the mountains of the S. and centre the chestnut abounds, and the walnut is found almost everywhere. The mulberry-tree, cultivated as support for the silkworm, is chiefly confined to the basin of the Rhone. Of the fruit-trees the principal is the vine, which grows in nearly all except the mountainous parts of F., yielding the best wines in Champagne, Burgundy, Franche-Comté, Dauphiné, Languedoc, and the Bordelais. Among the other fruits are the olive, apple, pear, cherry, plum, orange, citron, fig, pomegranate, lemon, and pistachio.

The country is essentially agricultural, and while the S. is rich in vines and fruits, the N. is equally productive in cereals. Everywhere, however, except between the Seine and the frontier of Belgium, husbandry is in a backward state. As a result of the equal division of land between the children of a proprietor, the area of F. is already held by some 5,550,000 owners, of whom 5,000,000 possess, on an average, not more than 6 acres each. One-half of the surface is under cultivation, one-seventh under forest and fruit trees, one-sixteenth is in permanent meadow, and one-seventh is unreclaimed waste. Three great agricultural belts traverse the country from S. to N. Thus the growth of the olive extends to a line stretching from the Corbières to the Alps of Dauphiné, the maize is cultivated to a boundary running from the island of Oléron to the middle of the Vosges, and the vine grows as far N. as the mouth of the Loire and the source of the Oise. More than a twentieth part of the surface is now covered with the vine, and the French have long borne the character of being the first of wine-makers. The production of wine greatly varies, and among the chief disturbing causes in recent years have been the fungus oïdium and the insect phylloxera. In 1869 the wine produced amounted to 1,364,000,000 gallons; and although of this quantity the great proportion is consumed in F., the value of the export to Great Britain alone, in 1874, was £2,616,355. The chief cereal in the W. is wheat, of which a considerable quantity is exported, and the average production of which is 275,000,000 bushels a year. In the S.W., as well as in the N., there is an extensive cultivation of flax and hemp, while the mulberry is a specialty in the vicinity of Lyon, the great centre of the silk manufacture. Among the other products are barley, oats, rye, buckwheat, hops, beans, peas, potatoes, and beetroot. There is also in the S. considerable production of rice, tobacco, madder, saffron, and other dye-stuffs.

Zoology and Live Stock.—The few wild animals yet remaining include the lynx, wolf, boar, chamois, and wild goat. Among the commoner animals are the roebuck, fox, marmot, ermine, hamster, squirrel, polecat, &c. Most kinds of game abound, but the red and fallow deer are scarce. Of birds the songsters resemble those of England; the more formidable birds of prey are the eagle, falcon, and buzzard. The flamingo haunts the Mediterranean shores. Several species of frogs, of vipers and harmless snakes, and of tortoises are the principal reptiles. Herring, mackerel, sardine, pilchard, turbot, sole, whiting, &c., are caught on the W. coast; tunny and anchovy in the Mediterranean, and salmon in the river estuaries. In the basin of the Arcachon, &c., there are large oyster and mussel beds. *Live stock.*—Of horses there are some 3,000,000; of asses, 413,000; of horned cattle, 10,000,000; of sheep, 35,000,000; and of swine, 5,000,000. The finest horses are reared in Normandy, while the Jura, the Vosges, and the basin of the Rhone are equally noted for their breeds of cattle. The yearly production of eggs is valued at £4,000,000, of which 28 per cent. is exported. There are £760,000 worth of honey and wax produced yearly in F. from 3,000,000 hives; the best honey is from Aude. Ardèche, Vaucluse, Drôme, and Gard are the great seats of the silk-culture, and previous to 1853, when disease broke out among the silkworms, the yield of cocoons amounted to 25,000 tons.

Industries.—F. has many and important industries, and of these perhaps the principal is the production of silks and velvets. Besides the raw silk produced at home, the amount yearly imported is over £4,000,000 worth. The weaving is done chiefly at Lyon, and in the department of the Rhone (120,000 looms), at St. Étienne and St. Chamond (ribbons and brocades), at Nîmes (light stuffs), and at Tours (silk furnishings). Silk lace is made at Alençon, Bayeux, Lille, Arras, &c. The northern towns (Rouen, St. Quentin, Amiens, &c.) are the most important seats of the cotton and woollen manufactures, while the linen industry is chiefly confined to Lille, Cambrai, &c. Since 1870 the making of printed calicoes has been limited to Paris and Rouen. Paris is noted for the variety and extent of its manufactures, including machinery, chemicals, porcelain, mirrors, clocks, watches, gloves, hosiery, *modes*, and above all jewellery. Another watchmaking centre is Besançon, where are mounted the pieces made in the Jura mountains. Over 200,000 tons of beet-sugar are produced (at Paris, Lille, Douai, &c.) from roots grown in F.; the total production is 325,000 tons. Raw sugar from abroad is refined at Marseille, Bordeaux, Havre, and Nantes. St. Étienne has great manufactures of firearms and hardware; Sèvres, of porcelain and glass wares; Rheims, of merinoes; Gobelins, of tapestry and cashmeres. Perfumery is extensively made in Paris and also in Provence.

Commerce.—In regard to commerce, F. ranks next to Britain among the countries of Europe. Its foreign trade nearly doubled in value from 1860 to 1874, rising from £167,000,000 to £304,000,000. In 1874 the total imports amounted to £148,720,440, and the exports to £155,110,120. The five chief articles of import were raw silk, corn and breadstuffs, wool, raw cotton, and coal. The exports were silk manufactures, woollens, wines, haberdashery and millinery, and refined sugar. The foreign commerce is mainly with Great Britain, Belgium, Germany, and Italy. The exports from Britain to F. in 1860 were £17,774,037; in 1870, £37,607,514; and in 1874, £46,518,571. The mercantile navy, exclusive of 'bateaux de la pêche côtière,' numbered in 1873 14,750 vessels of 1,064,379 tons, including 462 steamers of 141,520 tons and 57,510 horse-power. The chief ports are Bordeaux, Marseille, Havre, Nantes, Brest, Calais, Dunkirk, and Boulogne.

Railways, &c.—The growth of the modern railway system in F. dates from about 1840. The various railways, which are all subsidised by the state, are entirely in the hands of six great companies, viz., the Paris, Lyon, and Mediterranean, the Paris-Orleans, the Northern, the Southern, the Western, and the Eastern, having a total length (1874) of 12,822 miles, and a revenue of £31,894,612. At the end of 1874 there were 29,240 miles of telegraph lines, 78,174 of wires. The postal revenue from letters in 1873 was £3,560,550.

Finance.—The accounts of actual revenue and expenditure are

seldom published by the Government of F. till the lapse of seven years. The last final account or *budget réglé* was for 1869, and in that year the real receipts were 1,798,187,538 francs, and the expenditure 1,740,213,970 francs, surplus 57,973,568 francs. In 1876 the budget gave the receipts at 2,575,028,582 francs, and the expenditure at 2,570,000,475 francs. The sources of the revenue are the direct and indirect taxes, arising from stamps, imposts, customs, *droits d'octroi*, produce of forests and telegraphs, &c. The enormous increase of expenditure of recent years has been met by the imposition of new indirect taxes on sugar, wines, salt, transports by railways, &c. In 1793 all the Government debts, annuities, &c., were consolidated in a perpetual five per cent. *rente*, entailing an annual charge of 174 millions of francs. At first the dividends were only paid in *assignats* or paper of fictitious value, but six years later the Government was forced to compound with its creditors, which it did out of the confiscated property of the Church and the nobles. Thus at the beginning of the 19th c. the annual charge of the national debt was reduced to £1,600,000, or less than one-tenth of that of Britain. By the date of the Restoration (1814) the interest of the debt had only increased to 63 millions of francs, but under Louis Philippe (1830–48) the indemnity to the *emigrés* and other heavy war-debts raised it to 244 millions. During the empire this sum was gradually augmented, and in 1870 it amounted to 358 millions, representing a capital of 11,500 millions of francs or £460,000,000. Having been more than doubled by the war of 1870–71, and by the indemnity to Germany of five milliards of francs, it amounted on 1st January 1875 to a nominal capital of £937,584,280, bearing an interest of £29,936,196. The number of fundholders (over four millions in 1875) has greatly increased of late years, and the debt seems to be steadily undergoing a process of complete subdivision among the freeholders in F. All the departments and many of the cities have their own budgets and debts. The nominal capital of the debt of Paris in 1875 was 78 millions sterling, including a loan of ten millions sterling issued in 1875.

Army.—The army has been reörganised on the basis of a law of 1872, which enacts universal liability to arms, and disallows substitution or exemption for money. The law of 1872 has been expanded and modified by two Acts of 1873 and 1875. All Frenchmen between the ages of twenty and forty, not legally exempted, are liable to serve for five years in the active army, for four in its reserve, for five in the territorial army, and for six in its reserve. Among the exempted are those physically unfit, men who are essential to the support of a family, the pupils of the École Polytechnique and the École Forestière, teachers in public schools, professors, ecclesiastics, and artists who have gained the Grand Prix of the Institute. Young men, by enlisting as self-supporting volunteers for a single year, may obtain exemption from service in the active army. Soldiers of the active army who have learnt their duties, and can read and write, may at the end of a year procure a furlough for an indefinite time. The total effective force of the French army in 1875 was 430,703, comprising 277,004 of infantry, 68,281 of cavalry, 65,096 of artillery, 10,930 engineers (*génie*), 9392 *équipages*. The expenditure for the army in 1869 was £15,359,192, in 1875 £19,751,052. The whole of F. is divided into eighteen military regions, each containing a mobilised *corp d'armée*. Included in the effective force are four regiments of Zouaves, three of Algerian *tirailleurs*, four of *chasseurs d'Afrique*, three of Spahis, and four battalions of the *Légion étrangère*. Since the German annexation of Metz and Strasbourg, the fortified *chefs-lieux* or headquarters have been Arras, Avignon, Bayonne, Besançon, Bourges, Brest, Cherbourg, Grenoble, Langres, La Rochelle, Havre, Lille, Lyon, Marseille, Montpellier, Nantes, Perpignan, Quiberon, Rouen, St. Omer, Toulon, and Toulouse.

Navy.—At the end of 1875 the navy was composed of 63 ironclads, of 700 guns and 29,250 horse-power; 264 unarmoured screw-steamers, of 1547 guns and 55,812 horse-power; 26 paddle-steamers, of 154 guns; and 113 sailing-vessels, of 672 guns. There are in active service 2 admirals, 15 vice-admirals, 31 rear-admirals, 100 captains of first-class men-of-war, 202 captains of frigates, 640 lieutenants, 505 ensigns, 1028 officers of marine, engineers, &c., and 28,431 men in the ironclads alone. The navy is manned partly by conscription, and there are constantly on the rolls some 150,000 names. In 1875 the National Assembly voted £1,200,000 for the construction of fifty vessels, to be applied within five years. The great Government docks are at Toulon, Brest, and Cherbourg.

Constitution and Government.—The present constitution, voted by the National Assembly of 1871, bears date of 25th February 1875, and vests the legislative power in an assembly of two Houses, a Chamber of Deputies of 532 members, and a Senate of 300 members, and the executive in a chief magistrate called President of the Republic. The Chamber of Deputies is elected by universal suffrage under the *Scrutin d'Arrondissement* of 11th November 1875. By this law every arrondissement elects one deputy, and if its population exceeds 100,000, an additional deputy for each 100,000, or portion thereof. Deputy and voter must each have the qualification of citizenship, while the former must be twenty-five, and the latter twenty-one, years of age. Of the 300 senators, 225 are elected by the departments and by the colonies, whilst 75 are nominated in the first instance by the National Assembly, and subsequently by the Chamber of Deputies. Those for the departments are elected for the term of nine years, the others for life. The only necessary qualifications of a senator are that he be a Frenchman and forty years of age. The two houses of legislature must remain in session for at least five months in the year. The President is bound to convoke an extraordinary meeting if it is demanded by one-half of the members of each chamber; he can also adjourn the Chambers, but the adjournment may not exceed the term of a month, nor occur in one session more than twice. The President, who is nominated for seven years, and is eligible for re-election, is elected by a majority of votes by the two Houses united in National Assembly. He has the control of the army, promulgates the laws when they are voted, and appoints to all civil and military posts. But every act of the President must be countersigned by a minister; and the ministers, of whom there are nine, are responsible to the Chambers for the general policy of the Government. The President is only responsible in case of high treason. His salary is fixed at £25,000, with an extra allowance for household expenses.

Administration of Justice.—A special Minister of State presides over the administration of justice. There are 357 *tribunaux de première instance* for the arrondissements, 2681 police courts, 216 tribunals of commerce, and 26 courts of appeal. A *cour de cassation*, of three chambers, pronounces on all the sentences of the police and assize courts; and a *haute cour de justice* gives final judgment on state offences. There are 387 department prisons, 21 central prisons, the two political prisons of Doullens and Belleisle, the *bagnes* of Toulon, and the penal settlements of Guiana and New Caledonia.

Education, &c.—Public education is entirely under the supervision of the Government, and to a great extent in the hands of the Roman Catholic clergy. An official report on the educational state of the nation was issued in 1872, and revealed the following results:—Nine-tenths of the children under six years of age, more than a fifth of the youth of both sexes under twenty, and over a third of the adult population of men and women are unable to read or write. Setting aside some four millions of children under six years of age, it is estimated that 30 per cent. of the French are entirely devoid of education. There is, however, a vast difference in the degree of education among the various departments, to the credit of those in the N. and N.E. With Alsace and Lorraine F. lost the most highly-educated portion of her inhabitants. Throughout F. there are 42,000 free and public schools for boys, and 14,000 communal schools for girls. The Roman Catholics of the lower classes, especially in the rural districts, rarely visit school after eleven or twelve, the age at which they receive their first communion, while Protestants usually attend school till their sixteenth year. The expense is borne partly by the departments, partly by the state. The higher education of F. is represented by the University of F., by eighteen colleges of instruction in special branches of knowledge, eighty-one academies, many Latin schools, three high military schools (St. Cyr, La Flèche, and Saumur), &c. Among the great literary and scientific institutions are the Institut de F. (q. v.), the Conservatoire de Musique, the École des Beaux-Arts, the Bibliothèque Nationale, &c. There are rich art and scientific collections, and many charitable institutions, receiving yearly from the state as much as nine millions of francs.

Religion.—In 1872 the population consisted of 35,387,703 Roman Catholics, 580,757 Protestants (Reformed and Lutheran),

49,439 Jews, and 85,022 of various minor creeds. All religions are allowed by law, but only the Roman Catholic, Protestant, and Jewish Churches receive state allowances. In the Roman Catholic Church there are 86 prelates, 17 archbishops, and 69 bishops, 192 vicars-general, 723 canons, 3531 *curés* or incumbents, and 31,569 *desservants* or curates. The Lutheran Protestants, 80,117 in number, are governed by a general consistory, while the Reformed Protestants or Calvinists (467,531) are under a council of administration, the seat of which is at Paris. Mohammedanism is recognised in Algeria.

Colonies.—The dependencies of F. have a total area of 463,827 sq. miles, and an aggregate pop. of over two and a half millions. They include Senegal, Île de Réunion and Ste. Marie, Nossi-Bé and Mayotte, East Indian possessions, Cochin-China, Martinique, Guadaloupe, Guiana, St. Pierre and Miquelon, Marquesas and Loyalty Islands, and New Caledonia. Algeria (q. v.) is an integral part of F. by constitution of 1852.

History.—The earliest historic inhabitants of F. were Celts, known as Gauls, who held all modern F. except the S.W., and who, a considerable time after they had settled in the land, were driven into the E. and S.E. by the Belgæ, a Celtic people with probably an infusion of Teutonic blood. The S.W. of the country belonged to the Aquitanians or Basques, a shorter and darker people akin to the Iberians, and probably a survival from pre-Aryan times. The Gauls and Belgæ were blue-eyed and yellow-haired, eminently brave and intelligent, the Belgæ being more thoughtful and patient than the Gauls, who were above all mobile and keen-witted, full of unstable heroism, and delighting in brilliant colours and barbaric display. Both peoples were ruled by Druids and chiefs, and were divided into clans. Long before Cæsar's invasion the strength of the Gauls had been sapped by the pleasures and splendours of Rome, which interfered in their tribal quarrels, and before 118 B.C. formed the Rhone valley from Geneva to the sea into a Roman province (*Provincia Romana*, hence Provence). Rome won no fresh land in Gaul until Cæsar's proconsulship, B.C. 58-51. In campaign after campaign he routed the Gauls, until the capture of Alesia laid the whole country at his feet (B.C. 51). From B.C. 50 to A.D. 476 Gaul was a province of the Roman state, and her inhabitants received that Roman impress to which France owes her language, her law, her religion, and even several features in the character of her people. From Rome the Gauls acquired the love for centralised city life, for severe logical theories of government, and for the conceptions of the equality of man and of universal empire which have played so large a part in the nation's career. Southern F. especially was so deeply Latinised as to become a different land from F. north of the Loire, and to retain, during the middle ages, part of the law and a faint reflex of the civic life of Rome. Before the 3d c. Gaul was studded with fair cities, centres of commerce and luxury, whose governments, modelled on the Roman *municipia*, were the germ of the French southern *communes*. But along with the civilisation came the corruption of the dying empire, and Christianity, introduced in its Greek form in 160 by Pothinus, made little progress until Roman missionaries entered the country in the 3d c. In 251, however, Dionysius founded the church of Paris, and the conversion of the Gauls quickly followed. In the first half of the 5th c. the barbarians, who were breaking up the empire, poured into Gaul, the Burgundians seizing the region between the Rhone and Jura, the Visigoths occupying the S.W., and the Franks making raids through the N. and establishing a fluctuating power along the Lower Rhine. These tribes did not seize Gaul by a united invasion, but broke up the unity of the country by intermittent incursions, and by settling in separate bodies through the land. Commerce and agriculture were thus arrested, the national life was palsied, and the towns were cut off from each other and gradually enfeebled. Guizot traces French civilisation to three sources—ancient Rome, the Germanic invasions, and the early Church. Rome, he says, gave F. the ideas of law and order; the Teutons brought the sentiment of individual independence and passionate love of freedom, while Christianity cleansed the land from the impurities of an effete paganism. The Teutons strove in their new settlements to conform to Roman institutions and ideas, while the cities of Southern F. preserved the relics of the Roman municipal government. The Franks consisted of two main branches, the Ripuarians, who dwelt near Köln, and the Salians, who held the districts at the mouths of the Rhine. They were ruled by princes called Merwings, one of whom, Hlodowig (Clovis), in 486 overthrew Syagrius, who governed in the Roman name at Soissons, then embraced the orthodox faith, crushed the Arian Burgundians and Visigoths, and before his death, in 511, established a Frankish monarchy embracing most of modern F. On the death of his son Hlotair (Clotaire) in 567, three clearly-defined kingdoms began to arise —that of N. Gaul or Neustria ('the W. kingdom'), between the Loire and Meuse; that of Austrasia ('the E. kingdom'), between the Maas (Meuse) and the Rhine; and that of Burgundy, including the Rhone valley and part of Switzerland. The Franks were comparatively numerous in the N., where Orleans, Paris, Soissons, and Metz became capitals of Frankish kingdoms, but they had few if any settlements in Aquitaine and Burgundy. Under Dagobert, king of Neustria, the power of the Merwings was at its highest, but on his death (638) the Merwing kingdom faded away, and after the battle of Testry (687), in which the Austrasians under Pippin of Heristal defeated the Neustrians, Pippin and his descendants ruled over Austrasia and Neustria as Mayors of the Palace, the *rois fainéants*, or Merwing kings, being allowed to retain the name of royalty until 752, when Pippin the Short, son of Karl the Hammer—the Mayor who drove back the Saracens in the fight of Tours (732)—was proclaimed king of the Franks. The reigns of the Karolings, the empire of Karl the Great, belong to the history of Germany. Under Karl the Great Gaul was simply a province of a great German empire, as it had formerly been of the empire of Rome. The Merwing monarchy was in a degree French, Neustria being mainly peopled by Gallo-Romans, but Austrasia was a purely German land, the Karolings were German in blood, speech, and customs, and their favourite abodes were Aachen (Aix-la-Chapelle) and Engelheim in the Rhine valley. The Merwing monarchy arose from the warrior kingship of the Franks, the Merwings being encircled with peculiar reverence, as the descendants of heroes and demigods; while the Karolings dazzled their subjects by claiming to wield the universal dominion of imperial Rome. From neither of these monarchies is modern F. descended. Modern F. dates from the rise of the Parisian monarchy of the Capets, which gradually absorbed most of the old province of Gaul. The treaty of Verdun (843) severed Neustria, now a distinctly Romance land, from Teutonic Austrasia; and, down to the 14th c., the kingdom of Paris, which grew into modern F., possessed neither Burgundy, Provence, Elsass, nor Lothringen, nor had it for 600 years any firm authority over Aquitaine. Celtic or Romance F., as distinguished from Teutonic F., first appears at the treaty of Verdun in 843; Parisian F. first appears in 888, when Karl the Fat, for a time ruler of Germany, Italy, and Neustria, was deposed, and the Karoling empire split into the W. kingdom or F., and the E. kingdom or Germany, Italy, and Burgundy. From the death of Karl the Great Paris had been steadily rising in power, and her noble defence against the Northmen in 885 decided her future as capital of F. north of the Loire. She was not, however, at once made the capital of an existing French kingdom, but, on the contrary, from being the chief place of the county of Paris, grew into the kingdom of F., a kingdom distinct alike from the Roman province of Gaul and the W. kingdom of the Karolings. In 888 the nobles of the N. of F. chose Odo, the chief defender of Paris against the Northmen, as king, but he had to declare himself a vassal of the king of the E. Franks, and a century of constant rivalry ensued between the Karolings, who held their court at Laon, near the German border, and the house of Capet, which ruled at Paris—between the slightly-Germanised Romance kingdom of the W., and the Teutonic kingdom of the E. About the close of the 9th c. the Northmen made permanent settlements in N. F., and at length in 911 Hrolf (Rollo) received the lordship of the region between the Epte and Brittany, where he founded the great dukedom of Normandy. The Karolings growing more incompetent as the 10th c. advanced, in 987 Hugues (Hugh) Capet abolished the monarchy of Laon, thus breaking the ties between F. and Germany, the native land of the Franks. The subsequent history of F. until the end of the 18th c. is mainly concerned with the slow fusion of various provinces into the monarchy of Paris, and the gradual change of the kingly office from a weak overlordship into a despotism. Hugues Capet was merely one of the great peers of F., having only a faint superiority, except in his own domain, a tract of land hemmed in by Normandy, Brittany, Burgundy, and Aquitaine. The Capetian was distinguished from the Karoling monarchy by making no claim to represent the Roman empire,

and by its more essentially feudal nature. The fall of the Karolings had doubtless been hastened by the suspicions which the great barons, whose lands had been at first benefices granted in return for services at court, entertained towards the dynasty whose privileges they had usurped, and which had the right to reclaim the estates. A monarchy with less lofty pretensions was wished for, and was found in the purely feudal monarchy of the Capets. The new kings were more closely allied with the Church than were the earlier dynasties. A vague holiness began to be associated with the kingly office, and it is probably to ecclesiastical influence that we should ascribe the mildness and even feebleness of the early Capets, under whom the land was torn by feudal war, the nobles defying the kings, who could scarcely maintain the slight overlordship held by the first of their line. The Capetian kingdom was little more than a name until Louis VI. (1105–1137), with the aid of the Church, and by making common cause with the people, humbled the great feudatories of the crown. The king began to be looked on as the centre of justice, as the holder of a vague power which was dimly seen to be something apart from feudal overlordship, to represent the people and protect them from feudal oppression. Much of Louis VI.'s work was undone in the reign of hir feeble son Louis VII., whose supremacy the nobles shook off, and who was overshadowed by Henry II. of England. That king made war in F., not as an English sovereign, but as a great French feudatory, and held more land in F. than belonged to all the other French nobles together, while his feudal superior, the king of F., was a comparatively unimportant ruler cooped up in a small central district. But the mysterious popular respect still clung to the kingly office, and Louis VII.'s successor, Philippe Auguste (1180–1223) changed an unstable superiority coloured by an indefinite moral influence into a vigorous though still a feudal monarchy. He added Normandy to his realm by the capture of Château Gaillard (1204), and in the victory of Bouvines (1214), where he crushed the feudal barons allied with Otho of Germany, secured the future of royalty in F. He was greatly aided in his struggle with feudalism by the *communes*, which he favoured, and by the lawyers, who were becoming important through the reviving interest in Roman law. During his reign the brilliant civilisation of Southern F. was almost extinguished in the crusade against the Albigenses. Up to this time the S. had held aloof from the N., the Loire flowing between two lands widely different in the customs and even the race of their inhabitants. The Frenchmen of the N. were a mixed people of Celts, Franks, and Norsemen; the Aquitanians were partly Basques, partly Visigoths; and the Provençals had a considerable infusion of Roman blood. The S. had preserved a fragmentary code of Roman law in preference to the northern feudal *custom-right*, and contained many rich free cities, full of refined and democratic citizens, with governments based on the Roman *municipia*. Hlodwig's invasions of the S. had kindled a bitter hatred among the southern Gallo-Romans and Visigoths for the N., the land of the Franks—a feeling which remained throughout the middle ages, the early dislike of Aquitaine and Provence for the Merwings and Karolings being transferred to the monarchy of Paris. While the N. was torn by feudal strife, in the S., where the power of the Church was almost extinct, poetry, art, and philosophical speculation were assiduously cultivated. Southern F., imbued with Arabic science and cherishing Roman municipal rights, was bringing on a sceptical, democratic movement, intensely hostile to feudalism and the Catholic Church. Therefore the Pope stirred up a crusade against the Albigenses (q. v.), or heretics of Languedoc, and from 1207 to 1215 the barons of the N. slew and ravaged in the S. country, which never recovered its old wealth, luxury, and culture, though it still is, in the speech, customs, and blood of its people, aloof from F. north of the Loire. Louis IX. (1226-44) added to the royal domains by treaties and purchases, and while scrupulously recognising certain feudal rights, determinedly strove to root out the feudal privileges of private war and judicial duels. He has been called the founder of the French absolute monarchy, and his virtues gave the kingly office a popularity which in a large measure enabled it to grow into the foul despotism of the 17th and 18th centuries. In his reign occurred the last of the crusades, expeditions which had indirectly strengthened the French monarchy. At first the royal power gained by the crusades carrying off hosts of turbulent barons to the East, many of whom never returned to F., while the kings prudently stayed at home; and, afterwards, when the kings became leaders of armies to Palestine, their influence was increased by the lofty position they thus held before all Europe. The cities also throve from the crusades, which quickened their trade, and enabled them to buy privileges from barons who needed money to travel to the Holy Land, while, as each man who became a crusader was thereby freed, a vast number of serfs thus won their liberty, and both the cities and the new freemen were warm supporters of the crown. Under Philippe le Bel (1285-1314) the old feudal monarchy began to change into a despotism. In his reign we see clearly the baneful tendency to concentrate all power in the king, which ended in a systematic depressing of national life, in a general political ignorance, that bore fearful fruits in the days of the Revolution. While in England the free Teutonic institutions always survived in theory, F. in the time of Philippe le Bel had lost all the old Frankish popular rights. Hence reform in F. has always required changes wrought by abstract theory, the country having been, unlike England, deprived of foundations on which to build. Under Philippe le Bel all laws and administration emanated from the crown, the nobles were only consulted when war was intended. The lawyers at this time did good service in lessening feudal and ecclesiastical influence, but lent themselves to foster despotism. Being raised to offices at the will of the king they became his instruments in special commissions, and the monarchy thus won vast judicial power. After Philippe's death the monarchy was severely shaken throughout the 14th c., being assailed both as to the nature of the succession and as to the nature of its power. During the reigns of the three sons of Philippe le Bel (1314 28), peasant rebellions, famine, and disease desolated F., and on the death of Charles IV., last son of Philippe le Bel, the succession to the throne was disputed between Philippe Comte de Valois, cousin of the last king, and Edward III. of England, who claimed the crown as the son of Isabella, Philippe le Bel's daughter. The nobles, along with the 'notables of Paris and the other good towns,' decided in favour of Philippe, who then provoked Edward to war with the hope of annexing Aquitaine, the last remnant of the Continental kingdom of Henry II. of England. In 1337 began the struggle known as the *Hundred Years' War*. Under Edward III. the English won the victories of Crécy (1346) and Poitiers (1356), and took Calais during the first period of the war, which ended at the peace of Bretigny (1360), Edward giving up his claim to the French crown, and being declared the independent ruler of Aquitaine, Calais, and several small districts. At this time the condition of F. was unspeakably wretched, agriculture and commerce were at a standstill, and in 1348 the land was ravaged by the Black Plague. At length the peasantry rose (1358), and slew and plundered until the nobles ruthlessly quelled the revolt. From the common nickname of the peasants—*Jacques Bonhomme*—the name *Jacquerie* was given to this and all succeeding rebellions of like nature. Now, too, the Parisians strove to establish a free commune, under Étienne Marcel the provost, and assumed for the first time a revolutionary cap of red and blue. This effort, like the Jacquerie, was suppressed by the barons. In the reign of Charles V. (1364-80) the French gradually drove back the English, who before Edward III.'s death lost nearly all Aquitaine except Bordeaux and Bayonne. From the death of Edward III. to the invasion of Henry V. there were occasional truces, but no definite peace. During the reign of Charles VI., F. was rent by party strife, and Henry V. of England entered the country, won the battle of Agincourt in 1415, and by the treaty of Troyes (1420) was acknowledged successor to Charles VI. on the French throne. Charles VI. and Henry died in 1422, and war continued between the English regent, the Duke of Bedford, and Charles VII., who, mainly through the patriotic ardour of Joan of Arc, was crowned at Rheims in 1429. After Bedford's death the English steadily lost ground, until in 1453 Bordeaux and Bayonne fell, and Calais alone remained of their Continental possessions. Thus ended the Hundred Years' War, which left F. in the darkest misery. The country was desolate; in many provinces there was scarcely a house outside of the walled towns; the roads were overgrown by thickets; the peasantry had fled to the cities, where many of them were sunk into beggary. But the strength of the lesser nobles was broken by the war, and the towns were thus enabled to wring new liberties from them. An upper class of traders arose, and the *bourgeoisie* carried their influence to the side of the crown. Louis XI. (1461-83) favoured the third estate, and jea-

iously humbled the nobles. The 'third estate,' or the people, which now becomes somewhat important, sprang from the Roman municipal towns, which survived through the middle ages; from the *communes*, which won their independence by warring with the barons; and from the gatherings round a noble's dwelling of peasants and others, who, as they grew in numbers and practised trades, were enabled to win privileges from their overlord. The royal officers and lawyers, being mostly of low birth, were also a powerful element in the third estate, which rose in influence throughout the 15th c., though the communal liberties were now disappearing. In 1494 Charles VIII. marched into Italy, and, though his conquest of the country was ephemeral, the results of his invasion were momentous, as they committed F. to a ruinous policy, and led to disastrous wars with Spain. The next French king, Louis XII., was likewise inflamed by the hope of Italian conquest, but wasted his strength in intrigues of which Austria reaped the benefit. François I., the successor of Louis, plunged into war with the Emperor Karl V., and was captured at Pavia, the struggle between F. and Spain going on until 1558, when the Spaniards having won the victories of St. Quentin and Gravelines, the peace of Cateau Cambresis was concluded. These wars cost F. a lavish waste of blood and treasure, and infected her with the luxury and seductive vices of the South, but they also brought the impressible French into contact with a refined people, imbued with the spirit of the Renaissance, which was now diffused by the French through other nations. From 1562 to 1595 French history is mainly occupied with the civil wars between the Catholics and Protestants. The last, who were Calvinists, were known as Huguenots. During the reigns of Henri II.'s three sons, François II. (1559-61), Charles IX. (1560–74), and Henri III. (1574–89), great authority rested with their mother Catherine of Medicis, a bigoted Catholic, who foully abused her power in persecuting the Huguenots. In 1572 the massacre of the Protestants known as the Massacre of St. Bartholomew was perpetrated at Paris, and the struggle continued with shifting fortune until 1589, when Henri III. died. Henri of Navarre, a descendant of Louis IX., was now the rightful heir to the throne, but Paris and most of F. would not obey him, until in 1593 he became a Catholic and was made sole ruler, changing the old title *King of the French* for the new title *King of F. and Navarre*. Henri IV. passed the Edict of Nantes (q. v.) in 1598, and, supported by Sully, reformed many financial abuses, chastised the nobles, and protected the people. His popularity and Sully's ability rendered it unnecessary to summon the States-General to confer supplies, and the centralisation of power was thus largely confirmed. On Henri's murder in 1610 the government was administered by the Queen until 1614, when Louis XIII. nominally began to reign. At this time the ecclesiastical power somewhat declined in F., the king confirming the Edict of Nantes and other measures in favour of the Protestants, and the Catholic statesmen abandoning their former intolerant policy. Richelieu, the minister who really governed France during the last eighteen years of Louis XIII.'s reign, broke away from the old religious alliances, checked ecclesiastical influence in the state, and enforced the principle that national interests and not religious differences must determine political relations. The kingly power was further strengthened by Richelieu's antagonism to the nobles. He cut down their privileges and political importance, though he could not lessen their social power, which retained its malign influence until the Revolution. Under his indulgent policy the Huguenot party lost its importance and many of its members passed over to Catholicism. The Calvinist clergy, however, stirred up a somewhat factious resistance to Richelieu, and a war broke out, which was ended in 1628 by the capture of Rochelle, the great stronghold of French Protestantism. On the death of Louis XIII. (1648), F. was ruled by Mazarin, whom the queen-mother had made prime minister. Mazarin's unpopularity and the exactions under which the people groaned led to the rebellion of the Fronde (q. v.), in which the nobles, the *bourgeoisie*, and the mob of Paris rose together against Anne of Austria's regency. Even princes of the blood shared in the insurrection, and the Parisian populace, inflamed by over-taxation, was led by one of the ablest of demagogues, the Cardinal de Retz. But the movement only proved the inherent strength of the monarchy. There was no sympathy between the aristocrats who headed the struggle and the people. The nobles were blind to popular interests and large political issues, while the people were too ignorant to produce leaders from their own ranks. Another century was needed to imbue the populace with clear political convictions, with revolutionary ideas as well as revolutionary fervour. In the 17th c. there was nothing to take the place of the monarchy in governing F., and after the Fronde collapsed the royal power shot up into unexampled splendour under Louis XIV. He came to the throne in 1661, and his reign is the culminating epoch of the French monarchy. Before Louis XIV. the kingly power was checked by other influences, and after Louis XIV. it passed into a rapid decay. Up to this reign there was a possibility of the crown and people uniting to remove abuses. But under Louis XIV. all political activity on the part of the nation was frozen, all co-operation ceased between the ruler and the people, on the latter of whom it was now impressed that the king must initiate and carry out everything. The country laboured under evils so vast as to render the warmest co-operation between the crown and its subjects indispensable for their correction; and when the reform could no longer be delayed, the monarchy, isolated from the people by its systematic repression of national spontaneity, was unable to cope with the task of reform. Louis's reign began with success, but closed in gloom. At the end of the Thirty Years' War F. was the chief power in Europe, and under Louis XIV. stepped into the place from which Spain had fallen. Louis's policy of aggrandisement was at first successful, but in the Spanish war of succession his ambitions were shivered. His armies were defeated, the revocation of the Edict of Nantes (1685) deprived F. of a large industrious population, the revenue was scandalously misapplied, and on Louis's death in 1715 the national debt amounted to £140,000,000 sterling. Under Louis XV. costly wars were carried on with England, Spain, and Austria, and by the treaty of Paris (1763) the larger part of the French colonial possessions was given up. So gross was the misgovernment that F. was brought to a state of seemingly incurable bankruptcy and misery. The country was dying under the weight of the monarchy, when, in the days of Louis XV.'s successor, Louis XVI., the changes began which led to the French Revolution. The monarchy had engrossed all power, feudal, legal, and clerical ideas having combined to swell its authority. The feudal theory of monarchy made F. the king's private estate; the lawyers' theory, based on Roman ideas, made him the sole representative of the nation; and the clerical theory made him the delegate of God. And the government, while narrowly concentrated and inquisitorially administered, was rude and ineffective, the king failing to perform the functions which his office had engrossed. The country was overrun by tax-collectors—about 250,000 in number—who veiled their extortions behind the royal name. The nobles, suspected by the king and hated by the people, remained in defenceless isolation, debarred from all share in the government, while they still kept their galling rights and immunities, and spent their lives in the costliest pleasures. Louis XV. made Versailles the scene of habitual revels, recalling the foul orgies of imperial Rome, and consumed one-fourth of the public revenue in keeping up his household. As the 18th c. advanced, the state of the people grew more and more wretched. They were the only class engaged in productive labour, their exertions were hampered by absurd restraints, and upon them rested the sole burden of supplying the public revenues, the nobles being free from taxation except a merely nominal class-duty. In 1715 a third of the poor classes perished from want; in 1725 St. Simon said the king was making F. a hospital of dying men and women; and in the middle of the 18th c. the majority of the rural population could not with the utmost efforts earn enough bread to keep themselves alive, and at the same time pay the subsidies. Wide tracts of land were deserted; the peasants, unable to maintain life in the country, became beggars in the towns; 'starvation,' says M. Taine, 'was an endemic disease.' The ancient regime by its monstrous waste of the public resources, its *lettres de cachet*, its secret system of police, its endless confiscation of individual possessions, its forced services, its grinding taxation, its inquisitorial interference with private rights, had broken F. into bitterly hostile sects, and was actually maintaining an anarchy worse than that of the worst days of the Revolution. Meanwhile the intellectual class was wholly at variance with the existing institutions. The literary men—who had been systematically persecuted by the monarchy, and debarred from all share in public life, while they had no practical knowledge of government, but were inspired

by the old Gallic passion for equality, by an ardent belief in the perfectibility of man, and an intense hatred of existing social bonds, sentiments learned from Rousseau—were convinced that they could break with the nation's past, and mould society anew independent of its historic growth. As they were not mere speculative students, but lucid, fiery popular writers, they speedily imbued the people with their convictions; and to their wide influence, ignorance of practical politics, and passion for framing a government by theoretic doctrine, are due many of the wildest, emptiest follies of the Revolution. In 1789 Louis was forced by deficits to convoke the States-General, which had not met since 1614. On June 17 the third estate declared itself the National Assembly, and on June 23 proclaimed its members inviolable. The king then dissolved the ministry, and gathered a body of troops round Versailles, the result being that on July 12 insurrection flamed wildy out in Paris, and on the 14th the Bastile was taken by the mob. On August 4 the National Assembly—commonly known as the Constituent Assembly—abolished feudal rights; on October 6 the Parisian populace, their rage sharpened by accounts of the Versailles banquets, where royalists drank confusion to liberty, poured out, followed by the National Guard, to Versailles, and brought the king and queen back to Paris. This destroyed all the moral authority and mysterious inviolability which had till then clothed the French monarchy. In 1790 the king promised to conform to a new liberal constitution, while Austria, Prussia, England, Spain, and Saxony allied against his rebellious people. In 1791 the king and queen tried to escape from Paris, but were taken, and the Constituent Assembly gave place to the Legislative Assembly, which met October 1, 1791. At this time two great parties divided the revolutionists—the Girondins (q. v.) and the Jacobins (q. v.). The Austrians were now heard to be marching on F., and Paris broke out into mad fury. Henceforth until 1794 French history has to deal with two sets of events—with the repulse of the invaders, and with the violent struggles of factions in Paris. Each of 'the famous days of Paris' was prompted by the acts of the foreign enemies. On August 10 the Tuilleries were stormed in reply to the atrocious threats of the royalist Duke of Brunswick. The taking of Verdun and Longwy by the Prussians provoked the September massacres, F. being declared a republic September 25, 1792, and the loss of Cambrai led to the execution of Marie Antoinette. The king was guillotined on January 21, 1793, and the treachery of Dumouriez and rebellion of La Vendée called forth the rising of May 31, when supreme power passed over to the Jacobins, who won brilliant triumphs against the foreign enemy, and quelled insurrection at home, but, ignorant of ruling, and cruel through their fears and delusive hopes, plunged into the excesses of the Reign of Terror (q. v.), while the country yielded to them tamely, from its old habit of submitting to the crimes of the ancient regime. Reaction, however, swiftly set in. The leaders of the Jacobins fell, and the party broke up. (See DANTON, MARAT, HÉBERT, ROBESPIERRE, &c.) In 1795 the Convention made a new constitution, reposing the executive power with a Directory (q. v.) of five. Then followed the dazzling campaigns of Napoleon, who on November 9, 1799, overthrew the Directory and became Consul, and in 1804 Emperor of France. (See NAPOLEON). After Napoleon's final downfall in 1815, the Bourbon Charles X. was restored by the allies. Under him the dishonesty, incapacity, and priestly intolerance of the old regime were revived, until the revolution of 1830 placed Louis Philippe, Duc d'Orleans, on the throne. His stubborn enmity to reform caused his abdication in 1848, and the establishment of a republic. Louis Napoleon (q. v.) became president in 1848, and by the *coup-d'état* of 1851 Emperor of F. The Napoleonic absolutism endured until in 1870 the Emperor declared war against Prussia, and after sustaining a series of the most crushing defeats recorded in history, surrendered with 90,000 men at Sedan, September 2, 1870. He was then deposed, and a republic instituted at Paris, which city, after a resistance of four months, was entered by the Prussians, peace being made in March 1871. F. ceded Alsace and Lorraine, and paid an indemnity of £200,000,000. The revolt of the Paris Communists was energetically suppressed by the government of M. Thiers, and a Conservative republic was established. In 1873 Marshal Macmahon was chosen President for seven years, and in October 1877 when invited to express its opinion anew in regard to the form of government it preferred, F. once more decisively pronounced in favour of republicanism.

France, Isle of. See MAURITIUS.

Franche Com'té ('free county') was a province of the kingdom of France comprising part of the Jura mountains and the lowlands to the westward. It is now represented by the departments of Doubs, Haute Saône, and Jura. Originally possessed by the Celtic Sequani, it was conquered by the Burgundians in the 5th c., and after many changes was finally handed over to France by the treaty of Nymwegen in 1678.

Fran'chise, or **Lib'erty,** in English law, is a privilege by a grant from the crown, or by prescription which supposes a grant. It may mean the privilege of corporation, exemption from special tribute, a right over land, as that of *forestry*, the right to vote for a member of Parliament, and so on.

Fran'cia, José Gaspar Rodriguez, popularly known as Dr. F., was born at Asuncion, Paraguay, about 1757. He was of French or Portuguese descent, studied for the Church, and took the degree of doctor of divinity at the University of Cordova de Tucuman. Subsequently he left divinity for law, and gained a high reputation for ability, uprightness of conduct, and industry as a legal practitioner. The revolution among the S. American republics which made Paraguay independent brought F. to the front. In 1813 he was appointed joint-consul along with General Fulgencio Yegros; next year he was made dictator; and in 1817, such was the confidence of the Paraguayans in him, that he was appointed dictator for life, his death, looked upon as a great calamity, occurring September 20, 1840. The most widely different accounts are given of this remarkable man. In a celebrated paper of Mr. Carlyle, reprinted in his *Miscellaneous Essays*, he is eulogised as a stern administrator of justice, while Mr. C. A. Washburn in his *History of Paraguay* (1871) paints him as an absolute tyrant. Unquestionably he did a great amount of good to Paraguay, promoted education, suppressed clerical abuses, encouraged agriculture, cattle-rearing, and every form of industry which he could naturalise in Paraguay, established defences against the Indians, and made injustice almost an impossibility. On the other hand, there can be little question that he was merciless toward those who plotted or were believed to have plotted against his life, and was bitterly opposed to the intermeddling or even the presence of foreigners—*e.g.*, Bonpland the naturalist, and the Swiss travellers Rengger and Longchamp, who published their experiences of him in an *Essai Historique*, &c. (1827). For a full and unfavourable account of F. see three vols. by J. P. and W. P. Robertson, two Scotchmen whom he expelled from Paraguay; *Letters on Paraguay* (2 vols. 1838); F.'s *Reign of Terror* (1839); and *Letters on S. America* (3 vols. 1843).

Fran'cis, St., of Assisi, the founder of the Franciscan order, and one of the most interesting and pure-spirited of Catholic devotees, was born at Assisi, near Naples, in 1182. He was the son of a rich merchant, Bernardone Mariconi, and was named *Il Francesco*, from his command of the Provençal speech. He was early noted for gaiety, kindness to the poor, and lavish splendour of living, the people of Assisi calling him 'the flower of youth.' Having been captured in a feud with Perugia, he was imprisoned for a year; and during this confinement and a subsequent illness at Spoleto, his ideas permanently changed; he resolved to devote himself to a life of worship and charity, abandoning in his twenty-fourth year all his worldly goods, becoming a hermit, and, in his own words, 'taking poverty as a bride.' He preached with loving fervour, wore the meanest dress, performed the lowliest offices to the poor and to the lepers in the hospital of Gubbio, and aided with his own hands in the building of St. Damian's church in Assisi. When as a preacher he visited the Umbrian villages, the people went joyfully to meet him with flags and green boughs and music. Gradually he was encircled by followers, whom in 1210 he formed into the Franciscan Order (q. v.), which was verbally approved of by Pope Innocent III. in the same year, though first confirmed by Honorius III. in 1223. The peculiarity of the order was its utter abnegation of personal property, the brethren disclaiming possession even of their robes and breviaries. The order increased rapidly, and in 1219 had 5000 members. F. likewise founded the orders of *Poor Clares* and of *Tertiaries*. About 1220 he visited the East to convert the Sultan Meledin, whom he induced to promise kinder treatment of Christian prisoners, and to grant the Franciscans the

privilege of being guardians of the Holy Sepulchre. On September 17, 1224, according to the Catholic legend, he received in a religious ecstasy on Monte Alverno the marks of the wounds of the Saviour. He died October 4, 1226, having caused himself immediately before expiring to be laid on the bare ground of the church. St. F. is the most beautiful character in the history of mediæval Christianity—simple, childlike, and glowing with the purest emotion. His burning ardour was tempered by meek sympathies and undimmed by bigotry. Dante, who tells the story of his life, speaks of him as a 'splendour of cherubic light.' No one since the rise of Christianity brought religion so powerfully home to the people; his mystical raptures never lessened his yearning love for the poor. He completely changed monachism, transformed lonely ascetics into missionaries, and founded the most popular of all the orders. His *Canticle of the Sun*, written in artless Tuscan and thrilling with strange fervour, marks the rise of the lofty religious poetry of the middle ages which culminated in Dante. See St. Bonaventura's *Life of St. F.*; the Bollandist *Acta Sanctorum*; Chalippe's *Vie de St. F.* (1728); Chavin's *Vie de St. F.* (1841); Milman's *Latin Christianity*, vol. iv.; Vogt's *Der Heilige F. von Assisi* (Tüb. 1840); Hase's *F. von Assisi* (Leips. 1856); and Stephen's *Ecclesiastical Biography*. Editions of F.'s works, which consist of letters, monastic treatises, parables, hymns, &c., are numerous. The most accurate is that of Père de la Haye (Par. 1641).

Francis, St., of Paula, born at Paula in the kingdom of Naples, 1416, was named after St. Francis d'Assisi, to whose intercession his parents believed they owed the birth of the child. Having manifested strong ascetic tendencies even as a child, he was sent at twelve years of age into the Franciscan monastery of St. Mark, in Calabria, where he surpassed all the friars in obedience to their *rule*. On the expiry of his year of probation, after making a pilgrimage with his parents to Rome and other holy places, he took up his abode in a cave on the sea-coast, and devoted himself to a life of extraordinary asceticism. The fame of his sanctity soon attracted to him a number of followers, who built for themselves a chapel and cell in the neighbourhood, and he gave to the new order he had thus founded the name of the Eremites of St. Francis. In 1436 the Archbishop of Cosenza sanctioned the building of a cloister and church, and monasteries of the new order soon sprang up in Spain, France, and Germany. In 1474 the *rule* was confirmed by Pope Sixtus IV., and Pope Alexander VI. changed the name of the order to Fratres Minimi. Louis XI. in his last illness summoned F. to France, where in a monastery at Plessis-le-Tours the saint died, 2d April 1507. He was canonised by Leo X 1519.

Francis, St., of Sales, a bishop and prince of Geneva, was born at the château of Sales near Annecy, 21st August 1567. He studied rhetoric, theology, and Hebrew in the College of the Jesuits at Paris, and law at Padua, passed advocate at Chambery, and was strongly pressed by his father to become a jurist. But his heart was set on a sacred career, and in 1593 he entered the priesthood. The fame which he won by his first sermons pointed him out as a fit missionary for the district of Chablais, then filled with Protestants. In spite of great opposition, the brilliant young Catholic made numerous conversions, and inspired the Pope with the belief that he might perhaps succeed in winning over Beza (q. v.) himself, then the leader of French Calvinism. Three ineffectual conferences were held in 1597. In 1602 F. visited Paris, preached before Henri IV., who greatly admired him, and signalised himself by the miraculous conversion of courtiers. In the same year he succeeded to the bishopric of Geneva, and in 1607 founded the Florimontane Academy, and published his *Introduction à la Vie Dévote*, a work which excited a prodigious interest, was translated into several languages, and in less than half a century had gone through forty editions. Next year he again visited Paris, where his pious oratory once more brought the city to his feet. Every distinguished person sought his friendship or acquaintance. Cardinal Retz begged him to become his coadjutor and successor, but nothing could induce the modest bishop to abandon his Alpine diocese. Between 1610 and 1614 F. established the orders of the Visitation of the Barnabites at Annecy, and of the Carthusians at Ripaille. Two years later appeared his famous *Traité de l'Amour de Dieu*, which may be said to have evoked the admiration of Christendom. He now thought of resigning his episcopal functions, and passing the remainder of his days in some calm retreat, when the Duke of Savoy required his services at Avignon. On his return he fell ill, and died at Lyon, 28th November 1622. As a writer F. almost equals Montaigne in originality of style and the charm of diction. His *Œuvres Complètes* have been repeatedly published; the best edition is that of Blaise (16 vols. Par. 1835). F.'s letters in particular are exquisitely naïve and graceful. See Hamon's *Vie de Saint François de Sales* (2 vols. Par. 1854).

Francis'cans, Order of, named also 'Seraphic Brethren,' 'Minorites' (*Fratres Minores*) as a sign of humility, and 'Grey Friars' from the colour of their clothing, one of the great mendicant orders of the Romish Church, was founded by St. Francis in 1210, and confirmed by Honorius III. in 1223. The F. were vowed to chastity, poverty, and obedience, and their religious services were at first conducted with strict simplicity. They wore a grey cowl and robe, girded themselves with cords, and went bare-footed. The order grew with wonderful rapidity, and in the middle of the 13th c. had about 8000 convents and nearly 200,000 monks. 'Franciscanism,' says Milman, 'was the democracy of Christianity;' and at first, under the influence of Antony of Padua, one of their founder's disciples, the F. threatened to become bitter foes of the regular clergy; but they gradually forsook their early austerity, gathered riches, established a gorgeous ritual, and made their chief seat, Assisi, a centre of Christian art. During the 13th c. they were greatly favoured by the popes, who freed them from episcopal control, and allowed them to receive legacies, inter in churchyards, preach, and hear confession, independently of the regular clergy, by whom they were strongly opposed. From the frequency with which indulgences were granted them, the phrase *Portiuncula Indulgence* came into use, Portiuncula being the name of the church at Assisi where St. Francis had first collected his followers. The F. entered England in 1224, had a house first at Canterbury and afterwards at London, and in the beginning of the 14th c. the higher members of the order in England opposed Boniface because he refused to allow them to hold lands. There have been several offshoots from the F.—the Cæsarines separating in 1236, the Celestines in 1294, the Clarenines in 1302, and the Capuchins in 1525. Many who separated from the order were united in 1363 into the community of Soccolati, or sandal-wearers. The F. at first discarded learning, but afterwards included several of the greatest mediæval scholars, as Bonaventura, Roger Bacon, Hales, Occam, and especially Duns Scotus, who, with his followers, the *Scotists*, defended the doctrines of free-will and the immaculate conception of the Virgin against the Dominican Thomas Aquinas and his disciples the *Thomists*. To the F. also belonged the popes Nicholas IV., Alexander V., Sixtus IV., Sixtus V., and Clement XIV.; Thomas de Celano, author of the *Dies Iræ*, and Jacopone, author of the *Stabat Mater*. The order sank in the 15th and again in the 18th c. It now numbers about 100,000. The F. were once especially flourishing in S. America. The order of Tertiaries was founded by St. Francis in 1221 for such of both sexes as wished to observe some of the rules of the F., but were unwilling to take monastic vows. From the Tertiaries, who were in France called *Picpuses*, and who were very numerous in the 13th c., sprang the communities of the Fraticelli and Beghards. See Wadding's *Annales Minorum* (Rome, 1731–1744); Parkinson's *Collectanea Anglo-Minoritica*; and Milman's *Latin Christianity*.

Francis, Sir Philip, was born at Dublin, October 22, 1740. He entered public life on the Whig side in 1756, held a place in the Secretary of State's office, and from 1774 to 1781 was a member of the Council for Bengal, where he was wounded in a duel with Hastings. On returning to England he was elected to Parliament, and took part with eager enmity in the prosecution of Hastings. He left Parliament in 1807, and died in London, December 22, 1818. F. was an irritable but able man, and was influenced by sincere though splenetic patriotism. It is nearly certain that he was the author of the famous *Letters of Junius*. (See JUNIUS, LETTERS OF). See Merivale's and Parkes's *Memoirs of Sir P. F.* (Lond. 1867).

Francis'co, San. See SAN FRANCISCO.

Franck'e, August Hermann, a German educationalist, was born at Lubeck in 1663. Trained for the Church, he first became prominent through some lectures in Leipsic on biblical

literature, which provoked persecution and made him leave that city in 1690 for Erfurt. Finally he obtained a professorship of theology in the University of Halle, and having also accepted the pastorate of the suburb of Glaucha, he conceived the idea of promoting the education of the children of the poor in his district. Successful class-work induced him in 1698 to lay the foundation of an orphan asylum. To this he afterwards united a missionary institution for the East Indies, a Latin seminary, and a boarding-school. He was warmly supported in his philanthropic efforts by his countrymen, and a chemist gave him a receipt for compounding certain medicines which was the means of bringing him a considerable income. The education given in these institutions was distinctly and elaborately religious, and is so yet, though not to the same extent. They have been extended, and certain industries are taught in connection with them, such as bookselling and printing. The pupils number about 2500. F. died June 8, 1727. See Guerike's *Aug. Herm. F.* (Halle, 1827); Kramer's *Beiträge zur Geschichte Aug. Herm. F.'s* (Halle, 1861), and *Die Stiftungen Aug. Herm. F.'s in Halle* (Halle, 1862).

François I., King of France, born at Cognac, 12th September 1494, was the son of Charles Comte d'Angoulême and Louise of Savoy. He succeeded to the French crown on the death of Louis XII. in 1515 without children. F. was educated in the traditions of romance and chivalry, but entirely without reference to his duties as a sovereign. His first project was to recover the duchy of Milan, which he claimed through his wife as descended from the Visconti. He crossed the Alps with 40,000 men, his mother Louise remaining as regent. The Swiss, who had combined with Spain and Pope Leo X. to defend the duchy, were completely defeated in a two days' battle at Marignano, which was followed by the surrender of Maximilian Sforza and the battle of Milan. F. made a very temperate use of his victory, entering into friendly relations with both the Swiss and the Pope. Next year Karl succeeding to Ferdinand V. of Spain and the Emperor Maximilian, entered into the treaty of Cambrai with F., who also obtained the alliance of Venice. The apparent security of his position carried the French throne a long way towards absolutism, but the death of Maximilian in 1519 brought F. and Karl into collision as rival claimants of the Roman Empire. Despite the festivities of the Field of the Cloth of Gold, Henry VIII. inclined to the side of Karl, who entered into a league with Leo X. to expel the French from Italy. F., after some feats of arms in the Netherlands, saw Milan occupied by Prosper Colonna, and the governor Lautrec with his Swiss and Venetian allies routed at Bicocca, 29th April 1522. Then the English invaded Picardy, Bourbon deserted to the empire, Venice joined the Papal League, Bonnivet was defeated, and Bayard killed on the Sesia, 1524; and at last, after expelling his enemies from Provence and retaking Milan, F. by his own ignorance of strategy was defeated at Pavia, 24th February 1525, and became the prisoner of Karl. After nearly a year's captivity in Spain, he was freed on signing the treaty of Madrid, by which he gave up his claims on Milan, Genoa, Naples, Flanders, and Artois, and transferred Burgundy to the Emperor. By a secret protest of the same date F. declared the treaty null as signed under constraint. Then followed the Holy League (at Cognac, 22th May 1526) between Pope Clement VII., Venice, Florence, Milan, and F. against the Emperor. The result was another Italian war, in which, after Bourbon had taken Rome, Lautrec's army was destroyed in Naples, and the great Admiral Doria deserted to the imperialist side and liberated Genoa. After an exchange of cartels by the two monarchs, the Peace of the Ladies was negotiated at Cambrai by Louise of Savoy and Margaret of Austria, 5th August 1529. This confirmed F. in the possession of Burgundy, but stripped him of Flanders, Artois, and Italy. During the period of calm which followed, F. appears as the 'Father of Literature.' He patronised Budæus, Duchatel, Rabelais, and Robert Estienne, the great French printer of the Renaissance. But he never showed liberality to religious free thought, and his reign was marked by a series of *autos-da-fé.* The Edict of Toleration in 1535 was a mere political device to quiet the German Lutherans, whose neutrality he wished to gain, as well as the help of the Turks, in making another attempt on Italy. For this purpose also he had betrothed his son Henri to the Pope's niece, Catherine of Medici. Pope Paul III. at last reconciled Karl and F., who abandoned all his allies. In 1541, however, the murder in Milan of the French envoys on their way to Constantinople was made the occasion of another war. The Diet of Spires, indignant that F. should have brought the Turks to Nice, gave a large army to Karl, and Henry of England invaded Picardy. F., though victorious at Cerisolles (14th April 1544), was obliged to sign the peace of Crespy, which practically ratified those of Cambrai and Nice. Peace with England came two years later. The last years of his dishonourable reign were marked by an atrocious persecution of the Vaudois. He died at Rambouillet, 31st March 1547. F. founded the Royal College for three languages (Latin, Greek, Hebrew). See the *Mémoires* of Brantôme, Tavannes, Fleuranges, and De Montluc; also Gaillard's *Histoire de François I.* (7 vols. Par. 1760–69); Hermann's *Franz I.* (Leips. 1824); Röderer's *Louis XII. et François I.* (Par. 1825); and Kitchin's *History of France*, vol. ii. (1876).—**François II.**, born 19th January 1543, was the son of Henri II. and Catherine of Medici. He was married when Dauphin to Mary Stuart. He succeeded his father on the throne in 1559, but was entirely under the influence of the Guise family of Lorraine. St. André, Montmorency, the Bourbon princes, were driven from the court, and a wholesale persecution of Huguenots begun, which brought on the unsuccessful conspiracy of Amboise. Further troubles at Rouen and Grenoble suggested to the Chancellor L'Hôpital the Edict of Romorantur, which committed the crime of heresy to the clergy. This the Huguenots openly resisted; and the Assembly of Fontainebleau proving unequal to the occasion, the States-General were summoned to meet at Orleans, and in the midst of counterplot and treachery F. died, 5th December 1560. See Vaillas' *Histoire de François II.*, and Kitchin's *History of France*, vol. ii. (1876).

Franc'olin (*Francolinus* or *Ithaginis*), a genus of Rasorial birds included in the *Tetraonidæ* or Grouse family, and nearly allied to the Quails (q. v.). They have short bills, the fourth, fifth, and sixth quills being the longest of the wings; the tarsi have one or two spurs, and the outer toe is longer than the inner. The hinder toe is elongated. These birds are natives of Europe, Asia, and Africa. The common F. (*F.* or *I. vulgaris*) is found in S. Europe, N. Africa, and in many parts of Asia. A very familiar species is the sanguine F. (*F.* or *I. cruentus*), inhabiting the Himalayas at an elevation, according to Hooker and Gould, of from 10,000 to 14,000 feet. The prevailing colour of the male is a slaty grey, with a black forehead and line round the eyes, a red chin and throat, a green breast and abdomen, and a tail tipped with white. The bill has a red base and black tip. The female is of a reddish-brown colour spotted with black on the upper parts. The average size is that of an ordinary fowl. The food consists of pine and juniper tops and berries.

Franco'nia, or **Eastern** or **Teuton'ic Fran'cia** (Ger. *Franken*), a name applied to the fatherland of the Franks to distinguish it from Latin *Francia* or *France*, was a region in the S.W. of modern Germany traversed by the Rhine, the Neckar, and the Main. It was the heart of the empire under the Karolings. On the death of the Emperor Heinrich II., he was succeeded (1024) by Konrad, Duke of F., and a descendant of Otto the Great. Konrad, the first of the Franconian emperors, united the kingdom of Burgundy to the empire on the death of its king, Rudolf, in 1032. His son, Heinrich III., 'one of the greatest of all the emperors,' greatly restored the imperial authority in Germany and Italy. The oppressive rule of Heinrich IV. drove the Saxons to revolt in 1073. Disputes with the popes chiefly occupied the reign of Heinrich V., on whose death in 1125 the dynasty came to an end, to be continued through female descent by that of Swabia (q. v.). The duchy of F. now sank in importance, and became split up from time to time into many small states, as Nassau, Katzenellenbogen, Hainau, Rhenish Palatinate, &c. The old circle of F. was re-established by Maximilian in 1512, and included Baireuth and Anspach, several counties and cities, and the sees of Bamberg, Eichstadt, and Würzburg. At the fall of the empire (1806) the greater part of F. passed to Bavaria (q. v.), where the name is preserved in that of the divisions Upper, Lower, and Middle F.; the rest was distributed between Würtemberg, Baden, Hessen, Hessen-Darmstadt, Prussia, and Saxony.

Fran'eker, an old town in the province of Friesland, Holland, on a canal, 10 miles W. of Leeuwarden by railway. It is notable as the seat of a university founded in 1585, and

abolished by Napoleon in 1811, which boasted of many famous professors, as Heineccius, Vitringa, Schultens, Hemsterhuis, and Valckenaer. Pop. (1873) 4700.

Frangipa'ni, a noble Roman family which professed to trace its origin as far back as the 7th c., but which first becomes conspicuous in the 10th, when **Crescenzio F.** stands forward as the champion of the civil liberties of Rome against the encroachments of the popes. It played a prominent part in the long struggle between the popes and the German emperors. The F. uniformly took the imperial side; in particular, **Cencio F.** (12th c.) was the leader of the Ghibelline party in the time of the Emperor Heinrich V., but his career though turbulent has no abiding interest.

Frank'almoign ('free alms;' Lat. *libera eleemosyna*) is a kind of tenure in England by which a religious corporation held lands of the donor to them and to their successors for ever. The nature of the service under the tenure is not clearly defined, but the religious houses were bound by it to pray for the souls of the donor and of his heirs. Almost all the religious houses held their lands by F., and by it many ecclesiastical and charitable foundations hold them still, the nature of the service having at the Reformation been adapted to the doctrine of the Church of England.

Frank'enberg, a town in the kingdom of Saxony, on the Zschopau, 40 miles S.E. of Leipsic, with which it is connected by railway. It has large cotton and printing mills, besides manufactures of machinery, leather, Turkey-red dye, &c. Pop. (1871) 9710.

Frank'enhausen, a walled town in the principality of Schwarzburg-Rudolstadt, Germany, on the Wipper, 45 miles W.S.W. of Halle. It has a saltpetre refinery, and some trade in salt, corn, wool, and wine. Pop. (1871) 5221. On the neighbouring Schlachtberg ('Battle Mount') the Saxon, Brunswick, and Hessian troops quelled the peasant insurrection under Thomas Münzer, 15th May 1525.

Frank'enstein, an old town of Prussian Silesia, on the Pause, 45 miles S.S.E. of Breslau by railway. It has manufactures of linens, broadcloths, strawplait, and chemicals. Pop. (1871) 7171. About 7 miles to the S.W. is the strong rock-cut fortress of Silberberg, constructed by Friedrich the Great to command the road from Bohemia.

Frank'enthal, a town of Bavaria, in the Palatinate, on the Isenach, 3 miles W. of the Rhine, with which it is connected by a broad canal, and 9 miles S. of Worms by railway. It has large manufactures of woollen and cotton cloths, machinery, tobacco, &c. Pop. (1871) 7021.—There is another place of the same name in Upper Franconia, near the Thalrande, noted for its church (1743–72), which is visited on account of its 'miracles' by some 50,000 pilgrims yearly.

Frank'fort, the capital of Kentucky, U.S., picturesquely situated on the banks of the Kentucky River, is a station on the line of the Louisville and Lexington Railway. The State Capitol is a handsome building, and there are several important educational institutions. F. has two flour-mills, five saw-mills, a cotton-mill, and five distilleries. As the capital of Kentucky, it has been the centre of many stirring political events. Pop. (1870) 5396.

Frank'furt-on-the-Main, a city of Prussia, province of Hessen-Nassau, beautifully situated on the right bank of the Main, 20 miles above its confluence with the Rhine, and E.N.E. of Mainz. A place of great historical interest, it is now a great railway centre, and is entered by seven large gates, while its ramparts have given place (1804) to gardens and promenades. It has some twenty squares, of which the chief are the Rossmarkt ('horse-market'), with the monumental group of Fust, Gutenberg, and Schöffer, designed by Launitz; and the Goetheplatz, with the statue of Goethe (who was born in F.) by Schwanthaler. Among its sixteen churches is the cathedral of St. Bartholomew, begun in 1238 and finished in the 16th c., and in which the German emperors were crowned. It was restored in 1855, suffered from fire in 1867 and 1872, and been again restored (1876). The old stately townhouse, the Römer, still containing the Wahlzimmer ('election-room'), where the electors met, and the Kaisersaal, where the newly-elected emperor gave his first banquet, has of late years been enriched with portraits of all the emperors from Konrad I. to Franz II. Other public buildings are the Thurn-and-Taxis Palace, where the German Bund held its diets (1815–66), and the Saalhof, a modern imperial palace. There are also many educational and charitable institutions, literary and scientific societies, a medical institute (the Senckenberg), with a botanical garden and a large museum, a picture gallery, a public library of 100,000 vols., a theatre, &c. The chief street is the Zeil, 1215 feet long, in which are the large hotels. F. is visited annually by 120,000 persons, many of whom are attracted by the great fairs, which were already in their most flourishing state in the 16th c. The chief industries are printing, type-founding, and the making of jewellery, bijouterie, carpets, tobacco, sewing-machines; while as a place of trade, mainly in books, wine, timber, wool, silk, and leather, F. is one of the foremost centres in Europe. It is the banking-house of Germany, its exchange ruling the money market. The number of banks is over 100, while the aggregate capital is stated at twenty millions sterling, and the annual bills of exchange at twelve millions. The Rothschilds are the principal bankers; about one-third of the class are Jews. F. is connected with its suburb Sachsenhausen, on the opposite bank of the Main, by a stone bridge of fourteen arches (1340), by an iron suspension bridge, and by a railway bridge. The town is encircled by vineyards and orchards, which produce famous apple-wines. Pop. (1871) 91,040, of whom 25·8 per cent. are Roman Catholics, and 11 per cent. Jews, who once were restricted to a certain part of the city, the *Judengasse*. F. was the seat of a council convoked by Karl the Great in 794, and was the capital of the Eastern Frankish kingdom from 843 to 889. In 1248 it was made an imperial free city, and in 1356 the 'Golden Bull' of Karl IV. confirmed the custom of crowning the emperors here which had prevailed since the 12th c. Its geographical position early raised it to a high position as a place of trade. In 1806 Napoleon made it the capital of a grand duchy of the same name, and in 1815 it became the place of assembly of the Confederation Diet, at which it enjoyed an independent vote in the full council, and one in the united council conjointly with the other three free cities of Germany. F. sided with Austria in the war of 1866, and was annexed by Prussia, 18th October, after paying a fine of 31 million florins. The peace between France and Germany was concluded at F., the treaty being signed at the Swan Hotel by Bismarck and Jules Favre, 10th May 1871. See Böhmer's *Urkundenbuch der Reichstadt F.* (Frankf. 1836); Kirchner's *Geschichte der Stadt F.* (Frankf. 1807–10); Krug's *Historische topographische Beschreibung von F.* (Frankf. 1845); Battonn's *Oertliche Beschreibung der Stadt F.* (Frankf. 1863).

Frankfurt-on-the-Oder, a fortified town, and capital of a circle of the same name, in Brandenburg, Prussia, on the left bank of the Oder, 50 miles E.S.E. of Berlin by railway. It is connected by canals with the Elbe and Vistula, and has an extensive trade on the navigable Oder, which is here crossed by a bridge. F. was the seat of a university from 1506 till 1811, when the institution was incorporated with that of Breslau. It has a beautiful modern Marienkirche, several higher schools, manufactures of silk, leather, gloves, tobacco, mustard, &c., and large distilleries. There are three great annual fairs, attended largely by Poles, Silesians, &c. Pop. (1871) 43,214. F., an important Hanse town, was besieged by the Hussites in 1430, by the Poles in 1450, and by the Duke of Sagan in 1477, and suffered in the Thirty Years' War. Kunersdorf, 4½ miles from F., was the scene of a disastrous defeat of Friedrich the Great by the Russo-Austrian forces, 12th August 1759. See Sachse's *Geschichte der Stadt F.* (Frankf. 1830); and Spieker's *Geschichte der Stadt F.* (Frankf. 1853).

Frank'incense (Heb. *lebonah*, from *laban*, 'white,' Lat. *thus*) is a species of resin, of a white or pale-yellow colour, and agreeable odour when burned. There is much uncertainty as to the shrub or tree from which the resin exudes. According to Cant. iv. 6, 14, it was a native of Palestine, and according to Isa. lx. 6, and Jer. vi. 20, of Arabia, although these passages may merely refer to aromatic plants in general. At any rate, the F. now obtained in Arabia, of which it was said to be a native product by other ancient authorities besides the Bible, is of an inferior quality, and the best is brought from India, being

the product of a tree called the *Boswellia serrata*, or *thurifera*. F. has always been much used in sacrificial worship, being burned on altars or in censers that its odour might rise up as 'a sweet savour' to heaven. In the Mosaic ritual it was used as an ingredient of Incense (q. v.), with which it is not to be confounded (as it is sometimes even in the Authorised Version), along with the meat-offering (Lev. ii. 1, 16, xxiv. 7; Num. v. 15). It is still used in the religious rites of various Churches.

Frankincense Plant.

Frank'ing Lett'ers, a privilege conferred on peers, members of the House of Commons, and some other officials, by 4 Geo. III. c. 24. It entitled those holding it to send ten letters per day, not over an ounce in weight, by the post free of charge, to any place in the United Kingdom, and to receive fifteen free. The person franking wrote his name or title on the corner of the letter. The privilege was much abused, and by statute of 1837 it was so trammelled as to be almost unavailable. It was abolished on the introduction of the uniform penny-postage system in 1840.

Frank'lin, Frank'leyn, or **Frank'eleyn**, was formerly the name of an English landholder whose estates were free (Fr. *franc*) of any feudal superior. Franklins, at first, seem to have been men of considerable property, belonging to the national as opposed to the feudal party in the 13th, 14th, and 15th centuries. The name is familiar to us from the F. who narrates one of the *Canterbury Tales*, and whom Chaucer describes in the Prologue as a rich country squire, with a sanguine complexion and white beard, a lover of good cheer, and free dispenser of it to others—

'Hit snewede in his hous of mete and drynke,
Of alle deyntees that men cowde thynke.'

He was likewise 'lord and sire' at sessions, and had been 'schirreve' and 'knight of the schire.' In John Russell's *Book of Nature* a F.'s feast is described, consisting of numerous rich and savoury dishes, the F. seeming to have been the type of plenteous hospitality. Spenser's F., Zele, the personification of Christian energy, is—

'Faire and free,
And entertaines with comely courteous glee'—(Bk. i. v. 10).

From such passages in Shakespeare as the clown's saying in *The Winter's Tale* (Act v. s. 2)—

'I am a gentleman,
Let boors and franklins say it, I'll swear it,'

and Imogen's request for a riding suit 'no costlier than would fit a franklin's housewife' (*Cymbeline*, Act iii. s. 2), the F. seems in Elizabeth's time to have sunk in the social scale, and was probably a small gentleman-farmer or wealthy yeoman. Sir Thomas Overbury describes a F. as an 'ancient yeoman of England,' and as a paragon of prudence and quiet virtue.

Frank'lin, Benjamin, an American philosopher, patriot, and philanthropist, was born at Boston, January 17, 1706. As an apprentice in his brother's printing-office, he eagerly devoted his leisure time to reading such books as he could get hold of. He was especially fascinated by the *Spectator*, whose simple and graceful style he strove to imitate. His first published literary efforts appeared in his brother's newspaper, the *New England Courant* (begun 1720); but the discovery of their authorship led to a quarrel between the brothers, which resulted in young F. breaking his indenture and running away to Philadelphia in 1723. Under the patronage of Governor Keith, he visited England in 1725-26, and after his return established in 1728 the *Pennsylvania Gazette*, which exerted a great influence in Philadelphia and the neighbouring provinces, and raised its owner rapidly to fame and fortune. In it, as well as in his *Poor Richard's Almanac* (1732–57), he developed his notions of morality, embodying his teachings in short pithy sentences, which have in not a few instances passed into proverbs. The precepts he enforced he practised himself; and in his *Art of Virtue* he enumerated thirteen virtues by which he proposed to reach perfection. He took an active interest in all reforms calculated to benefit society; founded the Philadelphia Library (1742), the Philosophical Society (1744), and the same year the first academy, now the university. He began his investigations on the nature of lightning in 1746, proving its identity with frictional Electricity (q. v.) in 1752; and for his papers on this subject he was elected F.R.S. in 1775, and received the Copley medal. In 1753, he became Postmaster-General for the Colonies, and four years later went to England to urge the claim of Penn's representatives for exemption from taxation. He visited Scotland in 1759, and returned home in 1762. On the passing of the Stamp Act (1764), F. was again sent to England to remonstrate; and his exertions procured its repeal in 1766. His efforts, however, could not prevent the War of Independence, and after the rupture in 1776 he was among the first to sign the 'Declaration.' The same year he was sent on a diplomatic mission to Paris, where he remained till 1785, and earned a lasting popularity by his natural, simple, and dignified bearing, and his practical wisdom. After his return he remained at Philadelphia till his death, April 17, 1790. F. combined in rare balance the inductive faculty of the true man of science, the native tact of the politician, and the shrewd common sense of the man of business. His improvements and inventions had all a practical turn; and the untiring energy of his mind is well shown in the curious calculations which he made in his moments of leisure and relaxation. He left an Autobiography going down to 1757, and a voluminous correspondence of later date, which were published by his grandson, W. T. Franklin, in 1817. A complete edition of his works was published by Jared Sparks (Boston, 10 vols.). Various biographies have been written—by Condorcet (1790), Chasus (1841), and Mignet, in French, by Bauer (1803-6), and Schmaltz (1840), in German, and by Parton (1864) and Theodore Parker in his *Historic Americans* (1870).

Franklin, Rear-Admiral Sir John, the greatest of the Arctic explorers, and the first discoverer of a North-West Passage, was born at Spilsby, Lincolnshire, 16th April 1786. He manifested a passion for the sea from early boyhood, and in 1800 was appointed midshipman on board the *Polyphemus*, which in the following year led the attack at the great battle of Copenhagen. Shortly afterwards F. was transferred to the *Investigator*, commanded by his relative Captain Flinders, who was commissioned to explore and survey the Australian coasts. In this expedition F. acquired a knowledge of practical seamanship and nautical surveying. In the *Porpoise*, which superseded the *Investigator*, he was wrecked, and left with ninety-four persons on a low sandbank for two months. Appointed to the *Bellerophon*, he acted as signal midshipman in that ship at the battle of Trafalgar. At the siege of New Orleans he signally distinguished himself in a gunboat action, in which he was wounded. Promoted lieutenant, he commanded the *Trent* in the Arctic expedition of 1818, sent out towards the Pole by the Spitzbergen route. He was intrusted with the command of the first overland expedition to the Polar Sea in 1819-22, and during these years performed perhaps the most extraordinary journey on record—traversing 5500 miles, and surveying the N. coast of America eastward from the Coppermine River to Coronation Gulf, amid unparalleled hardships and sufferings from want and extreme cold. In a second overland expedition (1825 27), he surveyed the Polar shores W. from the Mackenzie River halfway to Icy Cape. On his return he received the honour of knighthood. As Governor of Van Diemen's Land from 1838-43, he merited and won the affectionate esteem of the colonists. He was appointed to the command of the fatal Arctic expedition of 1845, consisting of the ships *Erebus* and *Terror*, which were last seen on the 26th July 1845, near the S. entrance to Melville Bay. After wintering off Beechey Island in 1845–46, he sailed up Wellington Channel for a considerable distance, then returning, he sought for a passage by a southern route. He died on board his ship, June 11, 1847, off the N. coast of King William's Island, after establishing the connection between Barrow Strait on the N. and the previously-explored arms of the Arctic Sea on the S., and thus demonstrating the existence of a North-West Passage (q. v.). F. is the author of the *Narratives* of his famous overland journeys.

LADY JANE F., second wife of Rear-Admiral Sir John F.,

and the daughter of John Griffen, Esq., born about 1805, was married in 1828. After the Arctic expedition commanded by her husband had been 'missing' for three years, she (in 1848) offered substantial rewards to any navigators who might rescue or afford relief to the *Erebus* and *Terror*, and from this date onward the one paramount object of her life was to succour the lost expedition. At the sacrifice of her whole fortune, she fitted out and despatched several vessels to prosecute the search —the *Prince Albert* in 1850 and again in 1851, the *Isabel* in 1852, and the *Fox* (Captain M'Clintock) in 1857. M'Clintock (q. v.) was successful in discovering the fate of F., the destruction of his ships, and the fact that he was the first to discover a North-West Passage. In recognition of her husband's discoveries, Lady F. was presented with the gold medal of the Royal Geographical Society in 1860. Lady F., whose devotion and self-sacrifice during so many years were warmly appreciated by her countrymen, died in London, 18th July 1875.

Frank-Marriage (Low Lat. *liberum maritagium*) arises where lands are given to a man along with a wife, the daughter or cousin of the donor, without further words. In these circumstances, or from the use of the words F.-M., the law inferred that the land was to be the property of the spouses, and after them of their lawful issue: it created a tenancy in special tail. F. has been superseded by modern conveyancing.

Frank'-Pledge, the Norman name of the old English **Frith'-borh** ('peace pledge'), an association of ten men in common responsibility. It has often been confounded with the tithing, which though perhaps, like the hundred, originally a personal division of the host, certainly became in England a geographical division, the administrative unit for police and fiscal purposes. It was an English principle that every *landless* man should have a lord as his surety for judicial appearance, this was subsequently made universal. On the other hand, the tithing was bound to pursue a thief, and to do justice. But the laws of the Confessor direct men to combine in *frithborh*, or *ten-manne-tale* (in the N. of England), with a headman, or capital pledge, *borhs-ealdor*, or *frithborge-head*. These are mutual sureties: if a criminal escape, they must purge themselves of complicity, or answer for all damage done. The institution was, in cases of murder, extended by the Conqueror to the hundred. The 'view of F.-P.' consisted in keeping these associations in order by the infliction of fines. This was the duty of the local court, and the obligation of the *borhs-ealdor* to appear afterwards became useful as a machinery for representing the interests of towns. The duty passed as a manorial right to the court leet, where it still exists, at least in Yorkshire. For an account of the Irish system of F.-P., see O'Curry's *Manners and Customs of the Ancient Irish*, vol. i. pp. 196-205.

Franks, a great German nation, who first appear under that name on the Lower Rhine in the 3d c. A.D. They were probably formed by an amalgamation or confederacy of those tribes who dwelt in the same region in the 1st c.—the Sigambri, Chatti, Bructeri, &c.—and first became important when they overthrew Roman authority in Gaul. See FRANCE.

Franz I. (Stephen), German emperor, born at Nancy, 8th December 1708, was the son of Leopold Duke of Lothringen and the Princess of Orleans, niece of Louis XIV. In 1729 he succeeded to his father's duchies of Lothringen and Bar, but the preliminary treaty of Vienna (1735) provided that, on the impending extinction of the Medici family in the male line, the Duke of Lothringen should be made Grand Duke of Tuscany with right of succession in his family, and that the exiled King of Poland, Stanislas Leczinsky, should during his life have Lothringen and Bar, these duchies to revert to France. F., whom his Tuscan subjects disliked, and who had acted as commander-in-chief of the imperial army against the Turks, now became co-regent, and on the death of Karl VII. (1745) was elected emperor. By the peace of Dresden (1745) Prussia acknowledged F.'s imperial title. The history of the reign belongs rather to the life of Maria Theresa (q. v.). F. was a 'solid pacific gentleman,' engaged latterly in banking, farming the customs of Saxony, and for some time actually supplying the Prussian commissariat with meal. He was much opposed to the French alliance, and more interested in chemistry than in government. He died suddenly, 18th August 1765, at Innsbruck.—**Franz II. (Joseph Karl**, better known as Franz I., Emperor of Austria) was the eldest son of the Emperor Leopold I. and Maria Louisa, daughter of Charles III. of Spain. He was born at Florence, 12th February 1768, and on the death of his father in 1792 succeeded to the imperial title. He took part in the 'coalition of kings' against the French republic, but the brilliant campaigns of Napoleon in N. Italy forced on the peace of Campo Formio (1797), by which the Austrian Netherlands were ceded to France, and Venice was divided between the parties. The provisions of Campo Formio were substantially repeated at Luneville (1801), when the return of Napoleon from Egypt had destroyed the second coalition. In 1805, alarmed by Napoleon's assumption of the imperial title, F. called himself 'Erwählter Römischer Kaiser, Erbkaiser (hereditary emperor) von Oesterreich.' The third coalition was destroyed at Ulm and Austerlitz the same year, and by the treaty of Presburg F. gave up all his interest in Venice, recognised all the French institutions in Italy, and made large concessions of territory and privileges to Bavaria, Würtemberg, and Baden. On 6th August 1806 F. resigned the empire of the Romans. In 1809 he again declared war. The final result was the peace of Vienna and Schönbrunn. Salzburg and part of Upper Austria were given to Bavaria, the Illyrian Provinces to Napoleon as King of Italy, and parts of Galicia to Saxony and Russia. F. then gave his daughter Maria in marriage to Napoleon, and in 1812 agreed to assist him against Russia, England, and Sweden. After the tragedy of Moscow, he attempted to mediate, but failing, went over to the allies by the treaty of Töplitz, 9th September 1813. F. also succeeded in detaching Murat, now King of Naples, from his master's cause. The Congress of Vienna gave back to F. nearly all he had lost since Campo Formio except the Netherlands, and he retained his possessions in N. Italy. He also became the President of the new Germanic Confederation, which lasted till 1866. Austrian troops were in Lombardy and Naples in 1821, but otherwise the rest of F.'s reign was calm. He died 2d March 1835, and was succeeded by his eldest son, Ferdinand I. F.'s policy in the latter part of his reign was directed almost entirely by Metternich (q. v.).

Franz'ensbrunn, or **E'gerbad**, one of the most celebrated spas of Bohemia, 4 miles N.W. of Eger. It has four springs, mainly alkalo-saline, used in drinking and bathing. There are also mud and vapour baths. F. sends away yearly some 200,000 jars of mineral water. The springs were discovered in 1793.

Franz-Josef, Emperor of Austria, born 18th August 1830, was the son of Archduke Franz Karl and Sophia of Bavaria. The Italian revolution and that of the Hungarians made it necessary that F.'s uncle Ferdinand should abdicate, and his father having renounced his rights, F. succeeded (2d December 1848) with promise of a free constitution and equality of representation. This promise was broken, and the ancient rights of Hungary were destroyed. While Radetzky drove the Sardinians out of Lombardy, F.'s generals, with the help of Russia, suppressed the rising of Kossuth. By the edicts of Schönbrunn, ministerial responsibility was declared at an end, and sheer absolutism expressly claimed. Government was centralised at Vienna, and several financial and commercial reforms were carried out. In 1855 F. arranged a Concordat with Rome, doing away with nearly all the reforms of Joseph II. The Franco-Italian war of 1859 and the Prusso-Italian war of 1866 stripped Austria of Lombardy and Venice, and excluded her from the Germanic Confederacy, and the emperor at last devoted himself to the adjustment of the Austro-Hungarian question. Meanwhile the constitution of the Reichsrath was enlarged, and in 1862 F. sanctioned the principle of ministerial responsibility. He increased his popularity by liberating the Polish patriot Langiewicz. In 1866 he chose Von Beust as his prime minister, who was succeeded in 1871 by Andrassy. Chiefly through the exertions of Deák and Beust, the Dual Constitution (giving a certain amount of autonomy to Hungary) was adopted in 1867. In that year F. was crowned King of Hungary at Pesth. The heir-apparent of the empire is the Archduke Rudolf, born 22d August 1858 of Elizabeth of Bavaria.

Franz-Josef's Land, a name given to the territory discovered by the Austro-Hungarian Polar expedition of 1873-74. It lies in lat. 80°-83° N., and long. 50°-70° W., 345 miles N. of Nova Zembla, and consists mainly of four promontories, named Vichy, Wilczek, König Oscar, and Petermann Lands, the connection between which was not completely traced, and which partly enclose a deep inlet of the sea, entered by 'Austria Sund.'

The shores of Wilczek Land rise in a rugged precipitous range of hills, which send down enormous glaciers. Great part of the explored surface is covered with ice. There are some thirty islands in and about the mouth of the Sund, five of which are of large size.

Frasca'ti, a town of Italy, on the slopes of the Sabine Hills, 10 miles E.S.E. of Rome by railway. It has a cathedral and many splendid villas, as the Mondragon and Traverna of the Borghese family. Pop. 6000. F. was named from the *frasche* or underwood with which, on the destruction of the neighbouring Tusculum by the Romans, A.D. 1191, the fugitive citizens here erected huts.

Fra'ser, Simon. See LOVAT, LORD.

Fra'sera, a genus of Dicotyledonous plants, belonging to the natural order *Gentianaceæ*. The flowers possess a four-cleft calyx and corolla, and four stamens. The fruit is a capsule. A familiar species is *F. Walteri*, which grows in Carolina and Virginia, and is known in commerce as *American Calumba*, its root being used in pharmacy.

Fra'serburgh, a seaport of Aberdeenshire, on a bay one side of which runs out into Kinnaird's Head, 46 miles N. of Aberdeen, and 19 N.N.W. of Peterhead by railway. It is the centre of large herring, cod, and ling fisheries, and has one of the best harbours on the E. coast, constructed at a cost of £50,000. A quadrangular building at the W. end of the town was intended for a college by Sir Alexander Fraser, who procured a crown charter in 1592, and had it renewed and enlarged in 1601. Pop. (1871) 4268. F. was formerly called Faithly, but its present name was conferred on it in honour of its proprietor, Sir Alexander Fraser, by James VI. (1592), who also made it a free port, free burgh of barony, and free regality.

Fraser River, the chief stream of British Columbia, rises in two branches, one of which is 250, and the other 200 miles in length. These, uniting at Fort George, flow S. and S.W. through the province, and enter the Pacific nearly opposite the southern extremity of Vancouver Island. The length of F. R. from Fort George is 800 miles. It is navigable by ocean ships for 75 miles (to New Westminster), and by steamers for 150 miles (to Fort Hope). Its main tributaries are the Stuart and Chilcotin on the right, and the Thompson on the left. The river, which flows for the most part in deep *cañons*, is rich in salmon and in the *oulachan*, or candle-fish, a nutritious, oil-yielding smelt. Its basin includes nearly the whole of the province, and its valley embraces valuable fur districts and pasture lands, while timber abounds, especially in the districts around its lower course. But the F. R. is best known for the rich gold-fields along its banks, the yield of which, since their discovery previously to 1857, has been such as to constitute them the rival of the best 'diggings' in Australia or California.

Frater'cula. See PUFFIN.

Fratricell'i (Lat. *fraterculi*, 'little brothers') was originally the Italian name of the whole Franciscan order. When that order adopted the milder interpretation of their *rule* given by Pope Gregory IX., the more ascetic members, who insisted on the rule being observed in its literal strictness, were called the Zealous, Spirituals, &c. In 1294 some of the Spirituals in Italy obtained permission from Pope Celestine V. to form themselves into a separate community, and to them was reserved the name of F. Being persecuted by the rest of the order, they fled (1307) into France, and joined themselves with a sect of Spirituals there, followers of Peter John Oliva, who had separated from the order for the same reason. Pope Clement V. attempted, at the Council of Vienne (1312-13), to put an end to the schism by a compromise. John XXII., on the other hand, ordered the extirpation of the F., along with the Beghards (from whom they differed only in being real monks), and immense numbers of both were put to death in Italy, France, and Spain. The only protection they found was in Germany, from the Emperor Ludwig of Bavaria, who sided with them against the Pope. After the death of John, Benedict XII. and Clement VI. tried to heal the schism by gentle measures, in consequence of which many returned to the order from which they had seceded. When, in 1368, the Franciscan order was divided into the two sections of the Conventual Brethren and the Brethren of the Observation, the latter, who were in fact the Spirituals inside the order, were joined by some of the Spirituals who had formerly left it; but the F. and the Beghards as a body still held out, and continued at open war with the popes. They were severely persecuted by Nicholas V. and succeeding popes, but were not extirpated before the Reformation, at which time those that were left became Protestants. Besides their controversy with the Franciscans regarding poverty, the F. were distinguished by certain peculiar tenets, which were chiefly those promulgated by the pseudo-Abbot Joachim. They inveighed against the corruptions of the Church, and predicted a reformation and the restoration of the true gospel of Jesus. They also held that the true and eternal gospel of God, which indeed was to supersede that of Christ, was manifested to mankind by St. Francis. Hence it was that his *rule* was more to them than any number of papal bulls. See Mosheim's *Church History* (Reid's ed. 1860), and Milman's *Latin Christianity*.

Fratt'a-Maggio're, a town in the province of Caserta, S. Italy, 6 miles N.E. of Naples by railway. It has, among other industries, extensive rope-making, silk-culture, and fruit-rearing. Pop. 10,687.

Fraud. When F. enters into a contract, it prevents consent, and the apparent contract is void *ab initio*. F. giving rise to an agreement may be a ground of reduction of a contract, but it will have no effect in a question with a *bona fide* assignee for consideration. When the F. is not that of the party contracting, but of a third party, compensation can only be required from that party. F. may be by false representation, concealment of material circumstance, underhand dealing, or by taking advantage of imbecility or intoxication. In mercantile dealings, ordinary artifices to enhance the value of goods is not F. Every one is supposed to understand these, and to be capable of protecting himself against them. Neither is concealment of fact necessarily F., though circumstances may make it so. A knows and B does not that there is a mine on B's estate. In negotiating a purchase of B's estate A is not obliged to tell B of the mine. But if one man be in confidential relationship to another, he must not in negotiating with that other conceal material knowledge arising from the relationship. In this case the law requires *uberrima fides*, perfect good faith. Thus in Maddeford *v.* Austwick (1 Sim. R. 89) a contract was reduced by which the partner of a firm purchased the share of a copartner, the grounds of reduction being that the purchaser kept the books of the firm, from which he must have known that the price was inadequate, and that he concealed the inadequacy. It was, however, proved in the case that the book-keeping was intricate, that the plaintiff was not conversant with accounts, and that the defendant kept a private book. A contract will not be set aside merely because an honourable man would not have entered into it. There must be circumstances falling within some legal definition of F.

Fraud'ulent Bank'ruptcy is the wilful cheating of creditors by a bankrupt. The offence is usually committed by the bankrupt concealing part of his property, by falsifying his books, by stating fictitious losses, by connivance with fictitious or exaggerated claims, or by concealing important information from his trustee. The Bankruptcy Acts give ample powers to trustees in cases of F. B.

Fraun'hofer, Joseph von, a German physicist and optician, was born at Straubing, in Bavaria, 6th March 1787. In 1818 he became Director of the Optical Institute in Benediktbeuren, and in 1823 professor and conservator of the physical cabinet at Munich, where he died, 7th June 1826. He is celebrated as one of the founders of Spectrum Analysis (q. v.), the dark absorption lines of the solar spectrum being commonly known as *Frauenhofer's lines*. Of optical instruments invented or improved by F., we may mention a heliometer, an achromatic microscope, an annular microscope, and the great Dorpat telescope called by Struve the *giant refractor*.

Frau'stadt (Polish *Wszowa*), a fortified town of Posen, Prussia, near the Silesian frontier, 25 miles N.E. of Glogau by railway. It lies in a sandy plain, in which one can count 100 windmills, and has manufactures of cloths, yarn, dyes, &c. Pop. (1871) 6595. F. was founded by Germans, and belonged to the Princes of Glogau till 1343.

Fraxinell'a. See DITTANY.

Frax'inus See ASH.

Freckles. See EPHELIS.

Fred'eric (German). See FRIEDRICH.

Fred'erik I., King of Denmark and Norway, born in 1471, succeeded his nephew Christian II. in 1523. His policy was reactionary. The laws in favour of the peasants and the newly-printed books were publicly burned, the poor-schools were closed, and the Lutheran preachers expelled from the country. Shortly before the Diet of Augsburg there was an utter change in F.'s religious policy. He died in 1533.—**Frederik II.**, born in 1534, the eldest son of Christian III., succeeded his father in 1559. He completely crushed the Ditmarshers at the battle of Hejde. His foolish claim to bear the three northern crowns on his arms provoked the Seven Years' War with Erik XIV. of Sweden, in which the Danes ravaged Vestgoland, Smaaland, and Ostgoland, while the Swedes wasted Blekingen. Peace was secured at Stettin in 1570, Denmark giving up all claim to Sweden, and getting confirmed her rights to Norway, Skaania, Halland, and Blekingen. The statesman Peder Oxe restored order to the finances, improved the condition of the serfs, and introduced to Denmark many agricultural novelties. F. was a Lutheran, and compelled subscription by all Danish residents of twenty-five articles drawn up by Jacob Andreæ of Tübingen. He died in 1588. His daughter Anne was married to James I. of England.—**Frederik III.**, the son of Christian IV. and Anna Katherina of Brandenburg, was born in 1609, and elected to the Danish throne on his father's death in 1648. In 1657 began a war with Karl X. of Sweden, the result of which was the cession to Sweden of Trondhjem and Aggerhus in Norway, the old Danish provinces of Skaania, Halland, and Bleking, with the islands of Lesso, Anholt, Femern, and Bornholm. In 1659 the crown of Denmark was suddenly declared hereditary, and the sovereign absolutely independent. The royal secretary, Peter Schumacher, introduced important administrative changes and reforms in the naval, military, financial, and university affairs. F. died 9th February 1670.—**Frederik IV.**, born 11th October 1671, succeeded his father, Christian V., in 1699, and fought with Sweden and her allies. The war was ended by the peace of Frederiksborg in 1720. In 1721 the frivolous 'type quarrel' between F. and Count Görtz, regent of the Gottorp territory, and formerly minister to Karl XII. of Sweden, again produced war, and the duchy of Holstein-Gottorp was reunited to the Danish crown lands. F. by economy was able greatly to reduce the national debt. He also showed great benevolence in dealing with the pestilence which in 1710 cut off 25,000 people in Copenhagen, the fire which in 1725 destroyed two-thirds of the city, the inundation which in 1717 made useless the Ditmarsh pastures. F. sent out Ziegenbalg to the Danish mission at Tranquebar, and assisted the Greenland missionary Hans Egede. He also started a Greenland trading company. At home he did much for the serfs, and opened a number of free schools.—**Frederik V.**, born 31st March 1723, was the son of Christian VI., and succeeded his father in 1746. He married Louisa, daughter of George II. of England. After his marriage with Juliana Maria of Brunswick he became dissipated, and incurred heavy debts. Public affairs, however, were ably administered by Counts Schimmelmann and Bernstorf, the latter of whom encouraged trade, manufactures, and science. From Catherine II. of Russia Bernstorf obtained the treaty renouncing the Russian claims to Gottorp in exchange for Oldenburg and Delmenhorst. F. died 14th January 1766.—**Frederik VI.**, son of Christian VII. and Caroline Matilda, sister of George III. of England, was born 28th January 1768, and began to rule for his half-witted father in 1784. In 1788 a law giving complete freedom to the peasants was passed, and in 1792 the slave-trade was declared illegal in the Danish W. Indian islands. After the formation of the Second Armed Neutrality in 1800, however, the Danish practice of sending armed convoys with their merchant vessels led to Nelson's famous attack on Copenhagen. In 1807, England, suspecting a treaty between Denmark and France, sent Gambier and Cathcart to the Baltic, who destroyed the Danish fleet. When F., therefore, succeeded his father as king in 1808, the country was in a miserable state. In 1809 he issued 142,000,000 paper notes, which afterwards were suddenly reduced to one-sixth of their nominal value. This saved the literal engagements of the state, but greatly aggravated private misfortune. Even after the battle of Leipsic F. remained true to Napoleon, but was finally forced by the peace of Kiel (1814) to yield Norway to Sweden, obtaining instead Swedish Pomerania and Rügen, which were at once ceded to Prussia in return for Lauenburg and 2,000,000 rixdollars. Heligoland was ceded to England, and at the Congress of Vienna F. had to submit to be admitted to the German Confederation as Duke of Holstein and Lauenburg. Denmark slowly recovered from its depression, F. contributing much to the process by the establishment of a National Bank, and by the voluntary concession of Provincial Chambers in 1831. He died 3d December 1839.—**Frederik VII.**, born 6th October 1808, was the son of Christian VIII. On his father's death in 1848 Russian intervention caused the evacuation of Jutland by Mangol, and after some help had arrived from Oscar of Sweden, the great powers arranged the seven months' truce of Malmo, the duchies being put under five joint-commissioners. The contention of the duchies and of Prussia at this time was that the former constituted one state, subject to a male line of succession and part of the German Confederation. The Vorparlement, therefore, had jurisdiction to interfere by military executions. After more fighting at Ulleruss and Frederits, another arrangement for joint rule was made. In 1850 the Prussian general Willisen and the insurgent army were completely defeated at Isted, and the old Danish frontier, the Dannevirke, reoccupied. The duchies were then put under a Danish, Prussian, and Austrian commission. In 1850 F. granted a liberal constitution, which Denmark at present enjoys. He died at Glücksburg, 15th November 1863.

Fred'erick City, a city of Maryland, U.S., on the Baltimore and Ohio Railway. It has twelve churches, a handsome new town-hall, two collegiate schools, three foundries, three planing-mills, four large tanneries, three newspapers, &c. Pop. (1871) 8526.

Fred'ericksburg, a city of Virginia, U.S., on the S. bank of the Rappahannock, 92 miles from its mouth, and 61 N. of Richmond by railway. It has several large flour-mills, which are supplied with water-power by a dam stretching across the river. There are also iron-foundries, woollen-mills, and paper factories. F. was in great part destroyed in a battle between the Federals under Burnside and the Confederates under Lee, when the former were forced back across the river, with a loss of 12,321 men, 13th December 1862. Pop. (1870) 4046.

Fred'ericton, the capital of New Brunswick, in the Dominion of Canada, on a beautiful plain stretching along the right bank of the St. John, 84 miles from its mouth, and 105 miles N.N.W. of St. John by railway. It is the seat of a bishop, and has a university, a cathedral church, Government-house, courts, public libraries, &c. The river is navigable up to F. for large steamers. A steam-ferry connects F. with St. Mary's on the opposite bank of the river. Pop. (1871) 6006.

Fred'erikshald, formerly **Hald'en**, a seaport in the S. of Norway, in the amt of Smaalenen, on the Tistedal-Elv, an inlet of the Swinesund, 60 miles S.S.E. of Christiania. It is a splendid rock-bound harbour, and has a large export trade in timber and lobsters. In 1869 there entered the port 419 ships of 54,600 tons. F. is connected with Christiania by a regular line of steamers. In the Tistedal are beautiful waterfalls. To the E. of the port is the rock fortress of Frederiksteen, 400 feet high, which can boast of never having been taken in spite of many assaults. In one of these Karl XII. of Sweden lost his life (1718), and a monument was raised on the spot where he was killed in 1814. Pop. (1876) 9956.

Free Bench, a custom of dower which prevailed in some parts of England, under which the widow had the whole or the half of the lands held by her husband in Socage (q. v.), *dum sola et casta vixerit.*

Free Church of Scotland is the name assumed by the party which in 1843 withdrew from the Established Church and formed themselves into a separate religious body. From the first establishment of the Church after the Reformation there had been a constant tendency on the part of some Churchmen to claim that the Church was independent of the State, notwithstanding—nay, as some affirmed, even in consequence of—her establishment. And although the Revolution settlement appeared to give less ground for this claim than did the statutes of King James I., the Westminster Confession contains the assertion that 'The Lord Jesus, as King and Head of his Church, hath therein appointed a government in the hand of church officers

distinct from the civil magistrate.' It was a dispute regarding this claim that led to the Disruption of 1843, for the proper understanding of which it is necessary to go back to a point ten years previous to that event. The system of patronage, after being twice abolished by Parliament—in 1649 and 1690—was restored by the Act of Queen Anne, 1712. According to this statute a Presbytery was bound to ordain or induct to a vacant parish the qualified presentee of the patron, the call of the people being regarded as a mere form. The Evangelical party in the Church 'had always held it as a principle that the Church could not, without sin, act under any system of patronage which was subversive of the congregational call,' and that party, having now become the majority, passed in 1834 an Act called the Veto Act, according to which no minister was to be intruded on a parish contrary to the will of the people. In the autumn of that same year Mr. Young was presented by the patron to the parish of Auchterarder. But as a majority of the parishioners were opposed to his settlement, the non-intrusion party, as they were now called, in the Church declared the presentation to be null and void according to the Veto Act. Thereupon both the patron and the presentee appealed to the Court of Session, which decreed (1837) that the Presbytery proceed to ordain Mr. Young. The Court, in giving decree in this and all the subsequent cases, disclaimed any desire or any right to interfere with the Church, or to review or interfere with the decisions of her courts, when acting within her own recognised constitution; only it claimed, as representing the law, a third party, neither the Church nor the State, the right to decide, first, the *legal* point, that, in terms of the compact between the Church and the State, the former had no right to alter the constitution on the basis of which she was established, and therefore that passing the Veto Act was *ultra vires* of the Church; and, secondly, the *civil* case between parties within the Church, in which one party complained of being injuriously affected by the illegal proceedings of another.

As soon as this decision was given the non-intrusion party declared that the Church of Scotland was *the creature of the State*, or was Erastian in constitution, inasmuch as she recognised the right of the State to interfere, and of the civil courts to judge, in matters falling within the proper sphere and jurisdiction of the Church. And the same party declared in the General Assembly of 1838 (being a majority) that the supremacy and sole headship of the Lord Jesus Christ 'they would assert and at all hazards defend.' When the judgment had been confirmed on appeal by the House of Lords, May 1839, the General Assembly by a large majority passed a resolution pledging the Church implicitly to obey the civil courts in all matters of civil interest, but firmly refusing their control in things spiritual.

A case that had an important bearing on the controversy was the Stewarton case, which arose out of the Chapel Act, passed by the same Assembly which passed the Veto Act, and by the same party. According to that Act, districts in connection with 'chapels of ease' were to be erected into parishes *quoad sacra*, and their ministers to acquire the status of members of Presbytery. Such a parish was to be disjoined from the parish of Stewarton in 1840, when certain of the heritors applied for an interdict, which was granted, although the case was not decided by the Court of Session till January 1843. The non-intrusion party held the action of the civil courts in this case to be the most violent attack which had yet been made upon the Church, the foundation principle of which was Presbyterian—that all ministers are equal—and were prepared to accept an adverse decision as alone sufficient to drive them from the Church.

Meantime a number of other cases had been decided involving the same principle as the Auchterarder case. A second case arose out of the latter by the patron and presentee raising an action for damages against the Presbytery, which the Court of Session decided they were entitled to, a decision which was afterwards confirmed by the House of Lords. In the first case it had been decided by the Supreme Civil Court simply that the Presbytery had acted illegally in setting the presentee aside by the Veto Act; and from the injurious effects of this new interpretation (as the non-intrusion party considered it) of the law of patronage, the Church might have been protected by a change effected by the legislature in that law. When the negotiations for relief in that way failed, the party desiring it passed in the Assembly of 1842 their 'Claim, Declaration, and Protest,' which set forth the Church's constitutional principles concerning the headship of Christ, the various encroachments on her rights and liberties by the civil courts; the impossibility, consistently with her duty to Christ the Head, of submitting to the civil supremacy which had been assumed, and the necessity she would be under, if redress were denied, of withdrawing from her connection with the State. Matters were supposed to be made worse than ever by the decision of the House of Lords (August 1842), confirming on appeal that of the Court of Session in the second Auchterarder case. By this second decision it was declared that the obligation of the Presbytery to 'receive and admit' was a civil obligation, the violation of which was to be regarded and punished as a civil offence. The party held that the conditions produced by this new interpretation of the relation existing between the Church and the State (with which they always identified the civil courts, while the other party always regarded these as merely holding the legal balance between the Church and the State, and between different parties in the Church) were such that the Church could not fulfil them consistently with her principles. The crisis was produced by the decision in the Stewarton case (January 1843), and by the refusal of the Government (January) to take the Claim of Right into consideration, and the vote of the House of Commons (March) to the same effect. When the General Assembly met in May, the Moderator, Dr. Welsh, in his own name and that of 203 other members, read a protest, and the whole party withdrew and constituted themselves the Assembly of the F. C., with Dr. Chalmers as moderator. In the whole Church 474 ministers adhered to the Protest and resigned their livings. Since the Disruption, the F. C. has shared in the general prosperity of the nation. Its career has been marked (until recent years) by ecclesiastical vigour, well-defined policy, and able and energetic administration. As an evidence of the enthusiasm which marked its birth, it may be mentioned that the sum of £232,347 was contributed for its support during the sitting of its first Assembly. The maintenance of all the existing missions of the Establishment was boldly undertaken by the F. C., whose organisation was finally completed by the adoption of the Sustentation Fund (q. v.) and of an education scheme. In 1858 its doctrine of 'spiritual independence' brought it into something like collision with the State. The F. C. minister of Cardross was suspended for immorality. On the ground of irregularity in the ecclesiastical proceedings he appealed for redress to the civil courts. For this he was instantly deposed. The Court of Session, however, maintained its right to examine into the procedure of every 'voluntary association' for ecclesiastical purposes, not indeed to revise its ecclesiastical decisions, but to ascertain whether or not the compact between individual members and the society had been justly and equitably carried out. Negotiations with a view to the union of the Presbyterian Churches of Scotland were abandoned in 1873, mainly on account of the disinclination of the F. C. to modify its profession of the Establishment doctrine. The Reformed Presbyterian Church was received into the F. C. in May 1876. At the end of 1876 the F. C. had 984 ministerial charges, 34 'preaching stations,' and 39 foreign mission stations. Since the passing of the Education Act of 1872 most of the F. C. schools have passed into the hands of the School Boards. Colleges for the training of ministers and Normal Training Schools exist in Edinburgh, Glasgow, and Aberdeen. The aggregate sum raised by the F. C. of S. for all purposes from 1843 to March 31, 1876, was £11,782,978. See Innes's *Law of Creeds in Scotland* (Edinb. 1867); Buchanan's *Ten Years' Conflict* (Edinb. new ed. 1852); Brown's *Annals of the Disruption* (Edinb. 1876); Hanna's *Memoirs of Dr. Chalmers* (Edinb. 1854): on the other side, Bryce's *Ten Years of the Church of Scotland* (1850); *The Church of Scotland and the F. C., their Relation*, &c., by Veritas (Glasg. 1870); *Memoir of Dr. N. Macleod* (Lond. 1876).

Free Cities are in general those cities which became more or less independent during the middle ages, though the name is especially applied to the *free imperial cities* of Germany. These were at first closely connected with the emperors, and almost constantly at war with the nobles; but as the imperial power sank, they became practically independent, and formed leagues, such as the Rhenish League, which numbered seventy towns in the 13th c., and the great Hanseatic League, which, arising from a commercial treaty between Hamburg and Lübeck (1241), at one

time included eighty towns, monopolised the Baltic trade, had fleets and armies of its own, and opposed successfully the Swedish and Danish kings. Its various towns were divided into four sections, presided over by Danzig, Köln, Brunswick, and Lübeck —where the Diet was held. The League was broken up in 1630, about which time the German free towns fell into the power of oligarchies or petty princes. In Italy free commonwealths shone more brightly during the middle ages than in any other country. (See ITALY, HISTORY OF.) The French *communes* or free cities were in the S. of France relics of the Roman *municipia*, but in the N. arose mostly after the 11th c., when a fierce struggle began between them and the nobles. Aided by the king, the *communes* became in the 12th c. in a great measure independent of the feudal seigniors, but they never approached the political power and brilliance of the Italian commonwealths. Though having extensive local liberties, they had no influence on the state in general, and showed slight political activity, being often much influenced by feudal ideas. Never forming leagues, and weakened by the jealousy between their wealthy citizens and their poor inhabitants, they speedily yielded to the centralising tendencies of the monarchy. F. C. also arose in Switzerland, where they were united into a federation, but where their power was modified by the rural democracies. In England F. C. were hindered from appearing by the strength of the central government, and by the early diffusion of political power The cities of Aragon at one time held wide privileges. (See SPAIN, HISTORY OF.) See Gemeiner, *Ueber den Ursprung der Stadt Regensburg und aller alten Freistädte* (Munich, 1801); Guizot, *Civilisation en Europe* (Par. 6th ed. 1857).

Free'dom, Degrees of, in kinematics, are the number of independent variables in any displacement. For instance, a moving point has *three* D. of F., for the most general displacement it can take may be resolved into three parallel to three mutually independent directions, which are usually taken for convenience at right angles to each other. If the point be constrained to move on a surface, it has then two D. of F., for it cannot move along the normal, which may be chosen as one of three directions of resolution. If the point be constrained to remain on two intersecting surfaces, another degree of freedom is lost, the only possible motion being along the instantaneous tangent to the curve of intersection at the position occupied by the moving point. A free rigid system has evidently *six* D. of F., for besides having the three translations which the point has, it may have three independent rotations about three mutually rectangular axes. Fix one point, and the D. of F. are reduced to three—those, namely, of rotation. Fix another point, and the system has only *one* degree of freedom—a rotation round the straight line joining the two fixed points as axes. If a third point, not in line with the other two, be fixed, the system is fixed. If one point of the system be constrained to remain on a smooth surface, *five* D. of F. are left—two of translation and three of rotation; and each similar limitation to each of six points in succession removes one degree of freedom. A point constrained to move on a curve introduces two degrees of constraint, so the D. of F. are reduced to four. Other combinations will readily suggest themselves to the mind. See Thomson and Tait's *Natural Philosophy*, vol. i.

Free'hold Estate. The tenure of real estate in England is either freehold or copyhold. Freehold tenure owes no service to any one but to the sovereign.

Free Li'braries and Muse'ums. See LIBRARIES, FREE, and MUSEUMS, FREE.

Free'man, Edward Augustus, D.C.L., LL.D., one of the first of English historians, was born at Harborne, Staffordshire, in 1823. He is the son of John F. of Redmore Hall, Worcestershire, was elected scholar of Trinity College, Oxford, in 1841, and fellow in 1845. F. was examiner in the School of Law and Modern History in 1857–58 and 1863–64, and in the School of Modern History in 1873. He contested Mid-Somerset unsuccessfully in 1864; was made D.C.L. of Oxford in 1870, and LL.D. of Cambridge in 1874. He is a prolific author as well as a profound scholar. His works include *Church Restoration* (1846); *History of Architecture* (1849); *Architectural Antiquities of Gower* (1850); *Window Tracery in England* (1850); *Landaff Cathedral* (1860); *History of the Saracens* (1856; new ed. 1876); *History of Federal Government* (vol. i. 1863); *History of the Norman Conquest* (5 vols. 1867–76); *Old English History* (1869); *History of the Cathedral Church of Wells* (1870); *Growth of the English Constitution* (1872); *General Sketch of European History* (1872); *Historical Essays* (1st series, 1871); *Historical Essays* (2d series, 1873); *Comparative Politics and the Unity of History* (1873); *Historical and Architectural Sketches* (1876); *The Ottoman Power in Europe* (1877). Among the scholars who have devoted themselves to early English history, F. deserves the foremost place from his power of kindling interest in neglected epochs, and depth, freshness, and minute accuracy of learning, in which Gibbon alone is his peer among English historians. His *Norman Conquest* first disclosed the true nature of the Norman invasion, and in firm grasp of the subject, eloquence without exaggeration, and sound, far-reaching originality of judgment, is unequalled by any former English history. No book ever stated views so utterly subversive of all established opinion, which were yet so firmly based on historic fact. At times vividly pictorial, at times keenly critical and nobly reflective, the work is throughout steeped in learning, and bright with the enthusiasm of a patriot and a scholar. His *English Constitution* is a masterpiece of insight and brevity, and his *Essays* display his characteristic power of reconstructing without distorting history, of investing old-world contests with the interest of contemporary politics, and illuminating present questions from early annals.

Freeman's Roll. The Municipal Corporation Act directs that the town-clerks of nearly all the boroughs of England and Wales shall make out two lists of persons entitled to vote in the election of members of Parliament. One list is called the Burgess Roll (see BURGESS); the other is called the F. R. In it are the names of all who would have been entitled to vote before the passing of the Act.

Freema'sons are a fraternity consisting of persons of all ranks and professions, bound together by the ties of 'brotherly love, relief, and truth,' and founded in the 'practice of moral and social virtue.' In early times, prior to the invention of printing, freemasonry, or rather the masonic guild, was an institution of a more defined character, with an organisation springing immediately from the conditions under which building was carried on, with distinct purposes to subserve—with, in fact, a name to live. But the invention of printing has had an unfriendly influence upon it, mainly by abolishing the conditions in which the system naturally had its origin, and thus cutting away from it all justification for its continued existence. A minor evil which the printing-press has entailed upon freemasonry has been the facilities afforded for the ruinous support of injudicious literary 'brethren.' Masonic authors ascribe to the society an antiquity which varies more or less with the writer's credulity and ignorance. It is common, it not general, to date its origin from the period of the old Roman empire; but there are masonic writers who, unsatisfied with such a moderate degree of antiquity, trace the foundation of their system back to the days of the Pharaohs, to the building of Solomon's Temple, of the Tower of Babel, even to the days of the construction of the ark by Noah; while at least one author states that the founder of the brotherhood was Lamech, the sixth in direct descent from Adam, and that from his time the institution has been preserved inviolate and continuous down to the present day. That the institution of the thing now known as freemasonry is in any true sense ancient seems to be negatived on the ground that, were it so, an uninterrupted stream of architectural tradition, communicated to and understood by all the fraternity in every age, must have flowed onward through masonic societies down to the period when the invention of printing rendered tradition a superfluous method of transmitting information. But this was not the case, for we find that the technical secrets of the great builders of old died with them, and that even in comparatively modern times, after the age of ecclesiasticism had passed away, the Gothic architecture which in an earlier day it had called into being had vanished as a mode of architectural expression, and its principles, which by the theory of freemasonry should have been preserved and transmitted by tradition, were no longer known. The truth seems to be, that the masonic craft or guild, like the other crafts, sprang up after the Western nations had been taught to appreciate the luxuries of the East, and their growing wealth enabled them to gratify an improved taste. With the age of revival or *renaissance* crowds of artificers or craftsmen appeared, and

guilds, crafts, or trade societies were formed everywhere. There were special reasons why masons should form themselves into one great society. They were under the necessity of travelling from place to place in search of employment, and as it was desirable that a master-mason should be recognised as such wherever he went without being under the necessity of giving a fresh proof of his skill by way of testimonial in every new locality to which the necessity of finding employment led him, it was found to be convenient to establish a set of signs, words, &c., which, as the knowledge of them was intrusted to master-masons exclusively, had only to be communicated to prove membership of the craft. English F. profess to trace the existence of their craft as far back as the convention of masons held at York in 926, but there is not a shadow of evidence for such antiquity. The full title of the craft is the 'United Grand Lodge of Ancient Free and Accepted Masons of England,' under the protection of which there are over a thousand lodges. The Scottish F. are content to trace their descent from the builders of the abbeys of Holyrood, Kelso, Melrose, Kilwinning, the cathedral of Glasgow, and other buildings of the 12th and 13th centuries; but the date of the institution of the first masonic lodge is really unknown. The Lodge of Edinburgh (Mary's Chapel), however, has minutes of its transactions dating back into the 16th c., and in this distinction it has an advantage over the most ancient lodges in England and Ireland. The records of the lodge are in six volumes, still in good preservation, and the first of which contains the earliest lodge MSS. extant. The first minute is that of a meeting in 1599. The Duke of Athole is the Grand Master of Scotland. Modern or 'speculative' freemasonry dates from 1646—the earliest date at which non-professional masons are known to have been admitted into an English lodge. It is an invention of Elias Ashmole and some antiquarian friends, and all its quaint symbols—sun, moon, compasses, square, triangle, &c.—owe their symbolic meaning to the same learned source. The initiation of Frederick Lewis, Prince of Wales (father of George III.), by Dr. Desaguliers, the learned brother who in 1721 instructed the Lodge of Edinburgh in the secret ceremonial of English masonry, is the first undoubted instance of the admission to lodge membership of a prince of the royal blood. The evidence of this is the diary of one of the persons so admitted. In Scotland, however, as early as the latter part of the 16th c. the membership of lodges was not exclusively *operative*. For much interesting information on this subject, see the admirably temperate and scholarly *History of Freemasonry*, by David Murray Lyon (Blackwood, Edinb. 1873).

Free Port, a port where ships may be unloaded and goods deposited without payment of customs. If goods so deposited are reshipped, a mere transit-due is exacted; if they pass inland for consumption, they must bear the full duty.

Free Spirit, Brethren and Sisters of the, derived their name from maintaining that they were the true sons of God, brought into the most perfect freedom from the law, according to the words of St. Paul in Rom. viii. 2, 14. The sect made its appearance first in Strasburg in 1212, under the name of *Ortlibenses*, from a leader *Ortlieb*. Their doctrines spread among the Waldenses and Beghards. In Germany they sometimes got the name of *Schwestriones* ('sisterers'), and in France of *Turlupins*. Their doctrines, founded on Pantheism, were probably a revival of the Averroism of Amalric of Bena, condemned by the University of Paris, 1204. Their fundamental tenets were, that 'the universe came by emanation from God, and would finally return to him by absorption; that the universe, considered as one great whole, is God; that rational souls are so many portions of the supreme deity; and that a man by withdrawing his attention from all sensible objects might be so identified with the great first cause as to attain to perfect freedom.' Consequently they made religion to consist entirely in internal worship. Some seem to have interpreted the freedom of spirit they claimed to be superiority to every form of sensuality; others, if their orthodox persecutors are to be believed, to be freedom from shame and all manner of restraint on sensuality.

Free'stone, any building-stone that admits of being *freely* tooled and dressed. In Scotland sandstones are invariably so called.

Free'thinkers, as an historical name, is an epithet applied in England to the Deists (q. v.) of the 17th and 18th centuries. Otherwise it might be used to designate the great school of Rationalists who are to be found among all classes of Christians, and whose attitude towards Christianity is to represent its spirit and ideal without its dogmatic system and supernatural narratives.

Free'town, or **St. George**, the capital of Sierra Leone, W. coast of Africa, on the left bank of the river Sierra Leone, 5 miles from its mouth. It is the seat of the administrative, and has a garrison and a pop. of some 16,000.

Free Trade. The term expresses the condition of commerce left to follow its natural course, without legislative interference with the view of improving or influencing it. It was long the belief of the majority in England that the unfettered exchange of articles of commerce between one country and another was contrary to the general interest. Thus it would have been held, if London could supply Edinburgh with hats better and cheaper than Edinburgh could supply itself with them, that it would have been wise on the part of Edinburgh to tax the admission of London hats into its markets so as to make them dearer than those of home produce. It is now understood that, in the supposed case, it would only have been the hat-makers of Edinburgh who would have suffered by the free import of London hats into that city, and that the rest of its hat-wearing public would have gained money or—which is the same thing—saved it. The capital, labour, and ingenuity so driven out of the hat manufactory in Edinburgh would have borne fruit in some other industrial branch in which circumstances enabled Edinburgh to excel. The general wealth of London and Edinburgh would thus be increased, and the law of political economy in F. T. which prevails between London and Edinburgh has equal force between London and New York or between any communities of the world, the fact that London and New York are under different governments making no difference in the operation of the law. If *protection* be good between London and New York, it is equally good between New York and Boston—between Leeds and Bradford, or between one district of a town and another. The great battle between F. T. and *protection* has been fought in England on the field of the Corn Laws (q. v.). Since the victory then won by the advocates of F. T., the country may almost be said to have unanimously pronounced in its favour, the practical result having convinced the most obstinate incredulity. The average British and Irish exports for the period 1841–50 were of the value of £57,412,494; for 1871 their value was £282,380,726, showing an increase for 1871 over the period 1841–50 of £224,968,232. To some extent duties continue to be levied on foreign goods imported into England, but this is owing to the necessity of raising the imperial revenue. See BALANCE OF TRADE.

Free-Will. All human action, all social institutions, all that is known about the human mind, suggest that mental states (including volitions) succeed to one another in an orderly manner, and with the same apparent uniformity as purely physical changes. The connection of the mind and body being admitted within certain limits, the hypothesis of disorder or want of uniformity in the mind would necessarily affect the uniformity of the physical world. In cases like politics and individual character, not only have laws been traced, but accurate prediction has been made; and what are called incalculable elements in human nature and society are only so because imperfectly ascertained. A different theory was held by Socrates, who, believing that man himself was the proper subject of scientific knowledge, confessed that physics and astronomy were entirely in the control of the gods, and therefore unknowable except through the ordinances of religion. The modern theory of particular providences, *e.g.*, in deciding the obscure issues of disease, or grace deciding the soul to seize salvation, is merely a refined version of the view that the world is not governed by fixed laws. With the stoics and Philo-Judæus the 'free' man was the virtuous man, not in the sense of being free from restraint (at least moral restraint), but as the more dignified and elevated character. On the other hand, the bondage of sin was described as slavery. The distinct conception of freedom, in the sense of self-determination, there being a margin of indifference after the influence of every possible motive has been allowed for, was quite unknown to Plato or Aristotle, and was introduced to explain theological difficulties, original sin, and the Augustinian theory

of predestination. According to Augustine, Adam had F.-W., but none of his posterity. Evil was introduced by Adam's fall, and the human will is entirely governed by original sin on the one hand, and irresistible free grace on the other. Calvin went a step beyond this and rejected even Adam's F.-W. The opposite view of free choice (*liberum arbitrium*), as the foundation of the divine judgments and as limiting the divine foreknowledge, was upheld by Pelagius against Augustine, and in the 17th c. by Arminius against Gomar. Hobbes, in his tract on *Liberty and Necessity*, discusses the question without reference to theological interests. 'Doing or abstaining,' he says, 'necessarily follows the present thought a man hath of the good or evil consequence thereof to himself.' This occurs, however, only where the circumstances exclude deliberation, which is a succession of 'contrary appetites,' the last of them being the will. 'Liberty' he defines 'as the absence of all impediments to action that are not contained in the nature of the agent.' The will is the necessary cause of voluntary actions, and the will must have a cause else it would be eternal. Against this view Descartes appeals to consciousness: 'we are able to do or not to do the same thing,' however strong the motives on either side. It followed that the divine will was entirely indifferent, and this in a stricter sense than as regards the human will, because moral good and evil, the creatures of God's will, were not present to solicit it. Locke agrees with Hobbes and defines freedom as 'our being able to act or not to act according as we shall choose or will.' And he asks whether a man is free to will what he wills? Spinoza repudiates the notion of freedom in God, except in the sense of *unconditioned* existence and development, and of course human wills are not contingent, but are determined by the laws of the divine attributes. He points out that the favourite undetermined will of philosophers is a notion abstracted from all particular volitions, each of which has a cause. In his *Philosophical Inquiry concerning Liberty*, Anthony Collins adds a new argument to the controversy, viz., that except on the necessitarian view, punishment is inexcusable. Leibnitz applied to the problem his favourite principle of sufficient reason, which simply admits volition to be a case of universal causation, the agent being conscious. The pure-indifference notion was again stated by Samuel Clarke in the shape of a self-moving power which was equivalent to the spontaneity of the lower animals. This he defends by the whimsical objection that otherwise an abstract spiritual motive would be the cause of motion. The subject is nowhere better handled than in Jonathan Edwards' *Freedom of the Will*, which few books excel in clearness of language and vigour of thought. He examines in detail three meanings assigned to liberty:—(1) Self-determining power, the will causing its own volitions; (2) indifference or equilibrium; (3) contingency, or no fixed relations between motives and volitions. A thorough Calvinist, he supports his philosophical position by reference to the prescience of God. On the moral and practical side, Edwards truly says that what people love or hate is a good or a bad man, and not an ill-defined faculty of determination between two or more alternatives assumed to be perfectly neutral. A similar view was enforced by Priestley, who rashly declared that remorse was inconsistent with necessity. Reid reproduces at tedious length the opinions expressed much more clearly by Clarke and Price, and makes an impotent criticism of Leibnitz, saying that man is the cause of action. Hamilton, who said F.-W. was the only basis of morality and belief in God, considered the scheme of liberty, or of an absolute undetermined cause, and of necessity, or of an infinite retrogression of particular causes, as both inconceivable. Yet he rests his doctrine of liberty on the testimony of consciousness, or positive feeling, which is to be preferred to the causal judgment, because the latter depends on an infirmity of thought (the conditioned). Mr. J. S. Mill points out in his *Examination of Hamilton* that consciousness can only relate to what is or has been, and can therefore by no possibility disclose a power to do what is future. Mill also argues the point that it is just to punish a man for what he could not help, if that be the only way of enabling him or others to help it.

Free'zing and Fu'sing Points. One of the most important effects of heat is the alteration of the physical properties of bodies; the phenomena attending the transformation of solid into liquid or of liquid into solid will here be briefly noticed. When by the application of heat a solid *fuses* to a liquid, the temperature at which this change occurs is called the *fusing point*. When a liquid by cooling *freezes* to a solid, the temperature at which this change occurs is termed the *freezing point*. Thus when water, at ordinary pressure, is cooled to 0° C., it begins to freeze and become ice; and ice when heated to the same temperature begins to melt or fuse, and become water. Evidently, then, fusing point and freezing point, when used with reference to the same substance, represent one and the same temperature, though they imply reverse operations. When a solid fuses, it in general expands; and, according to the molecular theory, the molecules, formerly restrained to occupy the same mutually relative positions, now become free, through the diminution of the molecular forces of attraction, to shift about in the liquid. This has the obvious effect of giving to each molecule a motion of translation, that is, of increasing the internal energy of the substance, an effect which necessitates the disappearance of an equivalent amount of energy in some other form. Experiment shows that, as the solid is fusing, no rise or temperature is observed, though heat is being constantly applied. The thermal energy so absorbed is expended in changing the physical condition of the substance, and its equivalent is to be found in the probably increased internal energy. Precisely the reverse phenomenon is observed while a liquid is freezing or solidifying, the change of condition being accompanied with the evolution of heat. In all cases, however, while the change is taking place, there is no rise in temperature. That expansion is not essentially necessary for endowing the molecules with sufficient freedom of translatory motion is evidenced by the fact that some solids, notably ice, *contract* upon melting. Professor James Thomson deduced from the laws of thermo-dynamics that water, since it *expands* by freezing, should have its freezing point lowered by pressure, a theoretical result subsequently verified by the experiments of his brother, Sir William. The latter has extended the same law to embrace all similar phenomena, and has shown that solids which *expand* on fusing have their fusing points *raised* by pressure, and solids which *contract* on fusing have their fusing points *lowered* by pressure.

Freezing Mix'tures are combinations of two or more substances for the production of intense cold. One at least must be a solid, which is liquified when mixed with the other ingredients. This liquefaction requires the absorption of heat from surrounding objects, which is consequently lowered in temperature, and if liquid and near their freezing point, solidified. A quantity of pounded ice with half its weight of salt reduces a substance from +10° C. to −18° C.; while sulphate of sodium, nitrate of ammonium, and dilute nitric acid, in the proportions by weight of 6, 5, and 4, can reduce the temperature to −26° C. Other mixtures may be employed, and by a skilful combination of the best, very much lower temperatures obtained; but the minimum temperature hitherto obtained is about −90° C.

Fre'genal de la Sierr'a, a picturesque town in the province of Badajoz, Spain, in the wild valley of the Martiga, 30 miles S.E. of Badajoz. It has a quaint old castle, with a bullring, and industries in leather, linen, &c. Pop. 6948.

Frei'berg, a walled town of Saxony, on the Münzbach, a branch of the East Mulde, to the N. of the Erzgebirge, 20 miles S.W. of Dresden by railway. It is the administrative centre for the mines of Saxony, and the seat of a famous Mining Academy (since 1765), with thirteen professors and (1872) seventy-six students, Werner's celebrated mineral collection, and a library of 18,000 volumes. F. has a fine old townhouse (1410), and a cathedral with a 'golden gate' (1484-1512). Its manufactures are gold and silver wares, lace, woollens, chemicals, cutlery, and explosives: 150 mines of silver, copper, lead, cobalt, &c., are wrought in the vicinity. Pop. (1871) 21,673. The silver-mines of F. were discovered about 1190, but they have grown less productive of late years. See Benseler' *Geschichte F.'s* (1842).

Frei'burg ('the free or privileged city'), an old town in the Grand Duchy of Baden, lies on the Dreisam, at the W. base of the Black Forest, 45 miles S.S.E. of Strasburg by railway. It is the seat of an archbishop, and of a Roman Catholic university (since 1456). Its chief historical monuments are a beautiful Gothic minster in red sandstone (1152-1514), with a graceful tower 367 feet high, a quaint Kaufhaus (exhange) of the 16th c., and a grand ducal palace.

There are manufactures of leather, potash, starch, paper, &c., besides several dye-works, and a bell-foundry. Pop. (1871) 24,668.

Frei'burg, or the **Uecht'land** ('waste land,' so called because formerly a wild, uncultivated territory), is a western canton of Switzerland, lying between the lakes Neuchâtel and Geneva, and is bounded W. by Vaud and E. by Berne. Area, 563 sq. miles; pop. (1870) 110,832, of whom 93,051 are Roman Catholics, 16,819 Protestants, and 1400 Jews. F. is intersected in the S. by the Bernese Alps, which rise to the height in the Vanil Noir of 7346 feet, in Berra of 5307, in Dent de Brentlire of 7252, and in Follicran of 7215; it is watered by the Saane or Sarine, Broye, Seuse, &c. There is much fine wood and pasture. In 1870 the number of sheep was 23,206, of goats, 11,308, and of swine, 21,565. The chief industries besides husbandry are straw-plaiting, watchmaking, and the production of grass-tobacco, beet-sugar, and wine. Of the inhabitants 26 per cent. are German, 74 are French, the language of the latter prevailing, but in the form of a patois. The costumes are very picturesque. Since 1841 F. has been a member of the Swiss Confederation, and sends to the National Rath six representatives. The Jesuits were expelled in 1847.—**F.**, or **Fribourg**, capital of the above canton, is romantically situated in the deep valley of the Saane, and on its banks, which rise almost precipitously to a height of 918 feet. It is 17 miles S.W. of Berne by railway, is surrounded by old embattled walls, has twenty churches, five monasteries, four nunneries, one hundred inns, and many tanneries and dye-houses. The chief building is the beautiful Gothic church of St. Nicholas (1285–1500), which has a tower 280 feet high, a rare peal of bells, and a splendid organ of 67 stops and 7800 pipes. The river is crossed by four bridges, one of which has a single suspension span of 906 feet, a length exceeded by few bridges in the world. Pop. (1870) 10,904, mostly French Catholics. F. was founded by Berthold von Zahringen in 1175.

Freight (lit. 'that with which a ship is *fraught* or laded') is the price paid for the use of a ship to transport goods. It also denotes the goods transported. The terms of the F. are usually stated in the Charter-Party (q. v.), or in the Bill of Lading (q. v.). If a gross sum is stipulated to be paid for the whole ship or for any part of it, the money is payable though the freighter should not be liable to complete his lading. In payments by quantity, fractions of a ton, pipe, or pack, are not reckoned unless stipulated in the charter-party. F. is not due until the goods are delivered at the port of consignment; therefore if a ship be captured or lost, no F. can be claimed. But if advance-money has been paid, it cannot be recovered, nor can passage-money be paid in advance. If the agreement be for *landing* men or cattle, F. is due notwithstanding death, but if for transporting them, F. is not due for any dying during the voyage. No F. is due for an infant born at sea. If periodical payments are contracted for, and the ship be lost or captured, the owner is entitled to F. to the date of loss or capture. See AVERAGE, INSURANCE LAWS.

Frei'ligrath, Ferdinand, one of the most gifted of recent German poets, was born at Detmold, 17th June 1810, and was from 1825 till 1839 engaged in mercantile pursuits. Encouraged by the popularity of a collection of poems, he withdrew from commerce for a year or two, but political difficulties arising from the democratic spirit of his verses, led F. to return to business and settle in London in 1846. The commotions of 1848 brought him back to his fatherland, where he espoused the democratic side, and was prosecuted for his poem *Die Todten an die Lebenden.* Though acquitted now, F. had to retire to London again in 1851, where he was agent for a bank till its collapse in 1866. A national collection in Germany enabled him to spend his declining days in his native land. He published a few patriotic songs during the war of 1870, and died at Cannstadt, March 17, 1876. F.'s *Gedichte* reached a 27th edition in 1871, and collected editions of his works were published at New York (16 vols. 1858–59) and at Stuttgart (6 vols. 2d ed. 1871). F.'s translations have helped to make Burns and Longfellow known in Germany. His original poems are marked by wealth of imagery and glowing colour, with much true pathos, and a picturesque felicity of phrase more French than German; passion, however, often mars their beauty, especially in the numerous political and social pieces.

Frei'rina, a seaport of Chili, in the S. of Atacama, on the Huasco, with some export trade in copper. Pop. 10,000.

Frei'schütz is in German folklore the marksman who, by a paction with the devil, receives from him seven charmed bullets. Of these, six are sure to hit the mark, however distant; but over one of the seven the fiend has retained power to direct it as he wills. On this legend Weber's well-known opera is founded.

Frei'sing, an old town of Upper Bavaria, on the Isar, 20 miles N.E. of Munich by railway. It was the seat of a bishop from the 8th c. Its bishops were made episcopal princes by the Emperor Ferdinand (1619–37), but the see was secularised in 1803. The cathedral is a beautiful two-towered basilica of 1159. F. has manufactures of beer, spirits, tobacco, vinegar, &c. Pop. (1871) 7783.

Fre'jus, a town in the department of Var, France, on the Argens, 2 miles from the Mediterranean, and 45 N.E. of Toulon by railway. It is a bishop's see, and has many Roman remains, including an amphitheatre, part of an aqueduct, baths, &c. Pop. (1872) 2705. F. was founded by a colony from Marseille, and by the Romans was called *Forum Julii*, of which its modern name is a corruption. Its port, now silted up, was anciently of great importance. At St. Raphael, near F., Napoleon landed on returning from Egypt (1799).

Fremont', John Charles, a distinguished American explorer, of French extraction, was born in Savannah, Georgia, U.S., January 21, 1813, entered Charleston College in 1828, where he specially studied mathematics, engineering, and surveying, and where he graduated. In 1840 he was made lieutenant of engineers, and two years later explored the great South Pass in the Rocky Mountains, making valuable additions to our knowledge of the botany, geology, and geography of that region. During the next eleven years he made four expeditions westwards through territories then unknown, and in spite of terrible hardships and dangers, his dauntless courage and indomitable perseverance carried him successfully to the shores of the Pacific. His discoveries paved the way to the conquest of California, where he settled in 1849, and was chosen one of the United States' senators. The value of F.'s labours have been recognised in Europe. He is a member of the Geographical Society of Berlin, and has been awarded the founder's medal by the Royal Geographical Society of London. The new Republican party nominated him for president in 1856. His name elicited considerable enthusiasm, but he was defeated by Mr. Buchanan. He has since then devoted his time mainly to mining and to plans for trans-continental railways.

Fremont City, a town in Ohio, U.S., on the Sandusky river, and a station on the railway from Cleveland to Toledo, 30 miles E. of Toledo. It has three newspapers, good schools, a public park, and libraries, and carries on manufactures of cars, engines, boilers, and blinds. Pop. (1870) 5455.

French Beans. See KIDNEY BEANS.

French Berr'ies, or **Yell'ow Berries**, the fruit of the yellow buckthorn (*Rhamnus infectorius*), belonging to the *Rhamnaceæ* or buckthorn order. The name is also given to the fruit of the allied species *R. saxatilis* and *R. amygdalinus.* The berries afford a yellow dye when gathered in an unripe state. This dye, however, is not permanent, and has been superseded by mineral pigments. Y. B. are grown in the S. of France and in the Levant.

French Chalk, a variety of Steatite (q. v.) used for crayons.

French Hon'eysuckle (*Hedysarum coronarium*), a species of *Leguminosæ* included in the section *Papilionaceæ*, found in the S. of Europe, and having scarlet or white flowers. It grows to a height of 5 or 6 feet, and its pods, stem, and leaves are used as food for cattle. The stem is spreading, and the leaves are pinnate. F. H. is seen occasionally in gardens. *H. fruticosum* is a native of Siberia.

French Language and Literature. *French Language.*—The F. L. belongs to the Romance tongues which sprang from the Latin, and is at bottom a form, now vastly modified,

of the *Lingua Romana Rustica*, or vulgar Latin spoken by the Roman provincials, as distinguished from the Latin of literature. This provincial Latin arose from the colloquial Latin of the Roman soldiers and populace, which differed widely in pronunciation and vocabulary from the Latin of the classic authors, as we see from fragments of the *Atellanæ* or popular farces; and while the literary Latin sank into a dead tongue, the *Lingua Romana Rustica*, a modification of the *sermo plebeius* of Rome, developed into the Romance languages of France, Italy, and Spain, the leading differences between these speeches being due to varieties of race and climate, and to the respective distances of certain places from Italy. Even the literary Latin showed a tendency, in the times of the Empire, to become less involved, and make more frequent use of prepositions; and this tendency to simplify speech advanced far more swiftly in the vulgar Latin, which was guided by no high literary models. The *Lingua Rustica*, however, after it became the universal speech of Gaul, did not sink into a mere lawless jargon, but preserved several grammatical rules and the nominative and accusative cases. The nominative singular ended in *s*, because many Latin words had that termination in the nominative alone of the singular cases; on the other hand, the accusative plural was distinguished from the nominative plural by having the *s* ending, because in Latin the accusative plural often ended in *s*, a letter never affixed in the plural to the Latin nominative. A few Celtic words crept into the *Lingua Rustica* on its adoption by the Gauls, as *alauda*, *cervisia*, *margula*, *leuca*, the modern *alouette*, *cervoise*, *marne*, *lieu;* but the Celtic element in French is so small that M. Brachet pronounces its influence insensible, though it had a certain effect on the pronunciation of the *Lingua Rustica*. As the Gothic barbarians settled in Gaul in small detached bands, and differed considerably among themselves in dialect, they were forced to adopt the general speech of the Gallo-Romans, the *Lingua Rustica*; but they aided immensely to relax its grammar, as they seized on the part of a word which was unaltered by inflection, and ignored the endings, whose changes bewildered them. They also gave to the speech of the Gallo-Romans a number of Teutonic words, probably about 500 in all, mostly applying to war and hunting, and afterwards to feudal relations, and these words, like the Celtic element, were softened down till they seemed to be of Latin origin. (See DIALECT.) On the other hand, the old Latin words were shortened of their unaccented syllables, *e.g.*, from *securus*, *fidelis*, *legalis*, *surdus*, *solus*, *corpus*, *nasum*, came *seur*, *feal*, *loyal*, *sourd*, *seul*, *corps*, *nez*. When two consonants came together in Latin, one was dropped out, as in *advocatus*, which became *avoué*, or one of them blended with and changed the sound of the other, as in *altar*. *autre;* and when a Latin word began with *s* followed by a consonant, an *e* was prefixed for the sake of euphony, *e.g.*, *species*, *spissus*, *stringere* are now represented by *espèce*, *épais* (through the old *espois*), *étreindre* (through the old *estreindre*). The Latin ending *-sionem* or *-tionem* became generally *-son*, *e.g.*, *mansionem*, modern *maison*, the French words being almost invariably formed from the Latin accusative; *iculus -a -um* became *-eil* or *-il*, *e.g.*, *periculum*, modern *peril; -ilia* became *-eille*, *e.g.*, *mirabilia*, *merveille; aculum* became *acle; arius*, *aire; aticus*, *age*, &c. In place of the adverbial suffixes in *ter* and *e*, which vanished, because they were unaccented, the Gallic *Lingua Rustica* added *mens*—which was meant to denote in the manner or spirit of, and which is seen in the French *l'egalement*, *hardiment*, &c. The old conjugations were broken down, the old tenses, moods, and voices were abandoned. In the 9th c. the F. L. began to define itself from the other Romance tongues. It became rapidly more different from the written Latin, and in 813 a Council of Tours directed the bishops to translate their homilies from the Latin into the popular Romance. Our earliest specimens of the latter idiom are the fragment of a glossary (*Glosses de Reichenau*, about 770), and the Oaths of Strasburg in 842. The latter show that the Romance was, in the middle of the 9th c., the speech of the whole French army—Karl taking the oath before the Germans in Frankish—Hludwig taking it before the Roman-Franks or Frenchmen in Romance. The change of the Latin, through the *Lingua Rustica*, into French now went on rapidly, and in the 10th c. there were in France two strongly marked dialects—the *Langue d'Oil*, spoken N. of the Loire, and so called from using *oil* (Latin *illud*) for yes, and the *Langue d'Oc* spoken S. of the Loire, which used *oc* (Lat. *hoc*) as an affirmative. The *Langue d'Oc*, which was softer, more melodious, and more closely akin to the ancient Latin than was the speech of the N., early received a high literary polish from the *Troubadours* (q. v.), but was reduced to a provincial dialect after the civilisation of the S. was almost trampled out in the Albigensian crusades. The *Langue d'Oil*, spoken in the N., the land of the Franks, besides being less euphonious and graceful than the *Langue d'Oc*, was, unlike the speech of the S., broken up into many dialects, of which the most broadly defined were those of Normandy, Picardy, Burgundy, and the Isle of France. The last, from its central position, and from the political greatness of Paris, rose into pre-eminence, and became the classic form of the F. L., which, from the 11th c. onwards, was increased by words lifted from the old Latin almost in their original form (*e.g.*, *innocent*) through the influence of the learned, instead of having been, like the main body of the language, gradually changed by popular use from their old Roman into their modern French form. In the 12th c. *Old French*, as distinct from the *Lingua Rustica*, was fully developed. It was less synthetic than the Latin, but more so than modern French, and for a time kept the nominative singular and accusative plural in *s*, *e.g.*, nom. sing. *amis*, acc. sing. *ami;* nom. plu. *ami*, acc. plu. *amis;* but after the 14th c. the nominative of both numbers was disused, and *s* became the French plural ending, *e.g.* *ami*, pl. *amis*, the F. L. thus receiving a somewhat deceptive likeness to English, which about the same time chose *s* as its plural termination from one of its various endings in the older stage of the language. During the 12th and 13th centuries many Oriental words were introduced by the Crusades, and a number of Greek medical and philosophical terms were adopted, while several old Latin words were lost. There is considerable difference in spelling between old and modern French; thus, wherever there is a circumflex in the present dialect there was formerly an *s*, *e.g.*, *feste*, *fête*, *karesme*, *carême*, &c. The modern *peu*, *appui*, *sus*, *si*, are represented by *poys*, *apuys*, *super*, *sic;* words now obsolete are found, *e.g.*, *antan*, from *ante annum*, *sade*, agreeable, *aie* for *aide*, *het* from *hilaritas*, *oy* for the modern *ai*, *tiengne* for *tienne*, *querra* for *cherchera*, &c. In the 15th c. the language becomes simpler and more analytic, and is henceforth spoken of as modern French. During the 16th c. the F. L. received a large Italian infusion from the French expeditions into Italy and from the union between the house of Valois and Medicis, and was likewise imbued with a considerable Spanish element from the invasions of the Spaniards into France. When the revival of letters began to act on France, novel and pedantic terms were freely borrowed from the Latin, but this movement, which was justly satirised by Rabelais, had not a lasting influence. In the 16th c. Ronsard and the other members of the Pleiad wrote with assiduous nicety, showing a peculiar daintiness of phrase, as in their fondness for diminutives—*ondelette*, *fondelette*, *doucelette*, &c.—and Malherbe, Amyot, and Montaigne composed with rare copiousness, liveliness, and fluency; but on the founding of the French Academy (1635), a movement to prune and chasten the language set in, and though writers such as Voiture, Balzac, and Boileau made French admirably elegant, pure, and correct, the result of the prolonged and finical refining was to reduce the speech in the 18th c. to a state of colourless tenuity. From the middle of the 17th to the middle of the 18th c. the men of letters and the members of the fashionable circles united to polish and enfeeble the language; from which learned and technical terms, homely, colloquial, and picturesque words and phrases were alike filtered away, as unfit for polite society. Classic French, or the French used by all the writers—except La Fontaine, La Bruyère, and Voltaire—who come between Montaigne on the one hand and Rousseau on the other, is distinguished by strict order, delightful clearness, and antithetic brilliance, by the preference of general to special terms, by the absence of the old *Gaulois* brusqueness and freedom, and by a vocabulary shrunk to about one-third of its early wealth. The French Revolution, however, again altered the complexion of the language, which became elastic, fiery, and affluent, and which has received in the 19th c. a development unexampled in its history. Writers such as Chateaubriand, Hugo, and Gautier have enriched its vocabulary and shaken off the bonds imposed by the 'classical' school, the Romanticists in particular having gone back to the ample, delicate, and long-forgotten stores of the early French poets, and shown that sonorous strength and flowing sweetness may be qualities as characteristic of French as its more familiar merits of ease, precision, and lucid vivacity.

French Literature. —The Latin literature which flourished luxuriantly in Southern Gaul under the Empire, and which was mainly a polished, shallow imitation of the ancient classics, perished during the barbaric invasions, and it was not until the 11th c. that two great schools of poets arose in Northern and in Southern France. S. of the Loire there sprang up the lyrical school of the *Troubadours* (q. v.), who brought a wholly new species of poetry into Europe. Among the chief *Troubadours* were Bernard de Ventadour, Giraud de Borneill, Pierre Vidal, Bertrand de Born, Marcabrus, Rambaud de Vaqueiras, Folquet, &c. Their lyrics were exquisitely varied in metre, full of sweet and delicate though at times overstrained sentiment, and blithe vernal imagery, often flushed with Oriental colour, and occasionally reflecting the mystical, rebellious spirit which prevailed in Southern France about the end of the 12th c. Their measures depended on accent, as in modern verse, and not, as in Latin verse, on quantity, and have descended to us through the Latin hymns of the middle ages. Alongside of the *Troubadour* love poetry, whose deep subjectivity and ideal intensity of passion made it a poetry for the refined few, there seems to have been a more simple, gay, and homely literature of ballads, songs, and prose tales, of which the only known specimen is the charming story of *Aucassin and Nicolette;* but the popular as well as the aristocratic Provençal literature withered rapidly after the Albigensian crusades, the Langue d'Oc giving way to the Langue d'Oïl as the classic French dialect, and the *Troubadour* school becoming extinct before the end of the 14th c. The *Trouvères* (q. v.), or narrative poets of Northern France, far more than the *Troubadours*, were the fathers of F. L. The *Troubadour* poetry, despite its subtle pensiveness and enchanting melody, was fated to early decay; a strange, faint sickliness clung to it even in the time of its brilliant ripeness; and the *Chansons de Geste* of the *Trouvères*, far below the Provençal lyrics in artistic charm, were much more truly a national poetry. They dealt with war and adventure, and were mainly Gothic in spirit, though tempered by Gallic clearness and grace of expression, and lightness of fancy. The earliest known example of this Northern epical poetry is the *Chanson de Roland*, a heroic lay of the 11th c., belonging to the Carolingian cycle of the *Chansons*, which treats of the mythical Charlemagne and his twelve peers. This cycle includes such poems as *Ogier le Danois*, *Le Roman des Loherains*, *Charlemagne*, and is strongly feudal, but not yet chivalrous in sentiment. Chivalrous ideas are the leading feature of the second or Arthurian cycle, which began about the end of the 12th c., was largely drawn from Breton sources (see ARTHURIAN ROMANCE), and was followed by the Classical cycle, which transforms the history of Alexander, the Greek legends of Ulysses, Helen, Hector, and others, into wild tales of magic and knight-errantry. Among the foremost *Trouvères* were Chrestien de Troyes, Marie de France, Renaud de Montauban, Jean de Flagy, &c. In the 13th c. most of the *Fabliaux* (q. v.) were written, and lyrical poetry began to be cultivated in the N. of France, its authors, of whom Thibaut of Champagne was the earliest of note, at first imitating the *Troubadour Chansons*. Mock-heroic poems burlesquing the long chivalrous poems became popular in the 13th c., especially the famous *Roman de Renart* (see REYNARD). The greatest of the northern *Chansonniers* was Rutebeuf (q. v.). The long chivalrous epics gradually fell into disrepute, and quaint and frigid allegorical poems became common, the passion for symbolism taking fullest shape in the *Roman de la Rose*, where two great streams of French mediæval poetry—the allegorical and satirical—unite. (See MEUNG, JEAN DE, and LORRIS, GUILLAUME DE.) During the time of the Hundred Years' War, F. L. almost died out, Froissart (q. v.) being the only great French writer of the 14th c., and the poets Alain Chartier and Eustache Deschamps (q. v.) and the schoolman Gersen (q. v.) being almost the only notable authors in the first half of the 15th c In 1402 the first dramatic company, *La Fraternité de la Passion*, was founded. (For the French drama, see DRAMA, BASSOCHE, MIRACLE PLAYS.) History—which arose with Villeharduin (q. v.), Joinville (q. v.), and Froissart—is further developed by Philippe de Comines (q. v.), who substitutes the shrewd insight of a diplomatist for the simple gossip of the old chroniclers. During the 15th c. poetry is mainly taken up with the now trite themes and fancies of the earlier *chansons*, the praises of the spring, the sun, the grass, and the warbling of birds being tediously repeated. There is little original thought or deep feeling except in Charles of Orleans (q. v.), Saint-Gelais, and François Villon (q. v.). The last is the greatest French poet before Corneille, and from his blending of sadness, rich fancy, and wild mockery, foreshadows a characteristic phase of later F. L. He was the chief of the *bourgeois* poets, who paint the lowly and vagrant life of the middle ages, while Charles of Orleans represents the knightly aristocratic writers. Clement Marot (q. v.), who lived in the first half of the 16th c., is the last great writer of the old school—the last French poet who reflects the middle ages. The Renaissance began to act strongly on France in the early years of the 16th c., but did not, as in England, completely alter the course and the complexion of the national literature. In France the Renaissance literature was not a sudden growth of dazzling novelty and beauty, but was to a large extent the last flowering of the medieval literature with a fresh artistic subtlety and chastened splendour brought from Italy, the home of the new learning. At the end of the 15th and beginning of the 16th c. the rough, boisterous Gothic element seemed, as in Rabelais, about to absorb the Gallic lightness and literary grace which had played furtively across the old *chansons de geste*, and which were saved when the Renaissance became a potent influence on French poetry and prose. In the middle of the 16th c. the Renaissance movement was at its height in France, and the Gothic spirit, which had mainly produced the Northern epics, was blended with a new delicacy of style, the leader of the movement to refine the literature being Ronsard (q. v.), who founded the Pleiad, a poetic school so called because it included seven important writers. Its members wrote French verse with unwonted nicety of diction and exquisite variety of lyrical form, delighting in fantastic imagery, quaint learning, and ingenious rhymes; but the charm of their work was somewhat ephemeral, and their insatiable thirst for fine turns of language and rhythm taking hold of other writers, rendered poetry for a time trite and flimsy, the imitators of the Pleiad pursuing mere verbal felicities, to the neglect of true feeling and original thought. Henceforth French lyrical poetry languished until the beginning of the 19th c.

The chief writers in the first half of the 16th c. are Amyot (q. v.), the translator of Plutarch; Brantôme (q. v.), one of the most entertaining of French memoir-writers; Montaigne (q. v.), the earliest essayist; Rabelais (q. v.), the greatest of French humourists, who seems to gather together the Gaulois mirthfulness which runs riot through French medieval literature; Ronsard (q. v.), who was called the 'prince of the French poets,' and his associates in the Pleiad—Jodelle (q. v.), the first writer of a tragedy modelled on the Greek drama, and Joachim du Bellay (q. v.), the earliest memorable French critic, and the author of at least one exquisite lyric. At the end of the 16th and beginning of the 17th c. F. L. became more trifling and affected, though more polished in manner. Except in the *Satyre Ménippée* (1593), a scathing attack on the League, and in the works of Théophile de Viaud (q. v.), a graceful and pathetic poet, and Regnier (q. v.), a satirist who imitated Horace, and in a measure anticipated Boileau, there was little passion or earnestness among the writers of verse. The fashionable poet Malherbe (q. v.) purified the language from the antique words which Ronsard and his followers had coined, but while he gave the tongue new lucidity and precision, stripped it of the mellow and autumnal richness which hangs around the writings of the Pleiad. (See FRENCH LANGUAGE.) From 1600 to about 1650 euphuism was at its height in France. Long and unspeakably tedious romances, embroidered with fantastic ornaments in the manner of Gongora, full of cold and insipid gallantries, and affecting a mawkish purity of sentiment and stilted dignity of language, were composed by Gomberville, La Calprènede, and Mdlle. de Scudéry (q. v.); there was an endless supply of madrigals and other verses of society, where unblushing indecency was conveyed in flowery periphrases; sparkling frivolous verses were produced by Voiture (q. v.); and Scarron (q. v.), a really original writer, introduced burlesque into France. To this period of Spanish literary influences, of dreary euphuism, and polished immodesties belong, however, three of France's chief writers—Corneille (q. v.), her first great dramatist, and Descartes (q. v.) and Pascal (q. v.), who rank among the deepest European thinkers. During the period from 1650 to 1700, which may be called the age of Louis XIV., F. L. flourished in unexampled luxuriance. Boileau and Molière destroyed the euphuistic

school by the force of their ridicule, and a literature was developed rich in poetry, and marked by exquisite order, supreme good taste, and elegant rhetoric, but destitute of passion, depth, and spontaneous grace. The chief poets of the period were Molière (q. v.), Racine (q. v.), Boileau (q. v.), La Fontaine (q. v.); the leading prose writers were Malebranche (q. v.), Bossuet (q. v.), Fénélon (q. v.), Flechier, Bourdaloue, La Rochefoucauld (q. v.), La Bruyère (q. v.), and Madame de Sévigné (q. v.). In the 18th c. F. L. changes vastly in character; the formalism, equanimity, urbanity, and conservative indifference of the Louis XIV. period give place to bold sceptical discussion in politics and religion, and to a more free and varied literary manner. The old *esprit Gaulois* of Villon and Rabelais, which almost vanished under Louis XIV., reappears, while classical lucidity and order are in general preserved; literature, pervaded by a new philosophy born in England, no longer holds coldly aloof from everyday life; authors cease to re-set insipid generalities in graceful language, but grapple boldly and often rashly with practical questions. There is no longer the similarity between writers which prevailed during the latter half of the 17th c., the chief bond of union now being that the leading authors are mostly animated with identical philosophical tastes, and that all, save Buffon (q. v.), dabble in indecency. Saint Simon (q. v.), Fontenelle (q. v.), and Le Sage (q. v.) in a measure link the Louis XIV. school with the more characteristic authors of the 18th c., of whom the chief are Montesquieu (q. v.), Voltaire (q. v.), Diderot (q. v.), and Rousseau (q. v.). Montesquieu was the first to point out the true import and dignity of history; Voltaire, the incarnation of the century's scepticism, distilled the prevailing philosophy into tales, essays, histories, dramas, dictionaries, and burlesques, writing with unique piquancy and clearness; Diderot, a more vehement revolutionist, broke away wholly from the classic tradition, his powerful thoughts being mostly crudely though earnestly expressed; Rousseau is the earliest apostle of modern democracy, and from his passionate subjectivity, from the glowing liquid richness of his style, is the true parent of French Romanticism. The chief poet at the end of the 18th c. is Chenier (q. v.), and the chief dramatist is Beaumarchais (q. v.). Among the foremost writers during the early years of the 19th c. are Chateaubriand (q. v.), Du Staël (q. v.), Lamartine (q. v.), and Beranger (q. v.). In 1830 the French Romantic school was definitely recognised, and began a fierce struggle with the Classicists. Its leading members were Hugo (q. v.), De Musset (q. v.), Sainte Beuve (q. v.), Gautier (q. v.), De Vigny (q. v.), Dumas (q. v.), &c. (See ROMANTICISM.) Among the chief French authors of this century are Villemain (q. v.), Guizot (q. v.), Thierry (q. v.), Sismondi (q. v.), Michelet (q. v.), Thiers (q. v.), Louis Blanc (q. v.), in history; Hugo (q. v.), Nodier (q. v.), Balzac (q. v.), George Sand (q. v.), Mérimée (q. v.), Murger (q. v.), About (q. v.), Sandeau (q. v.), Dumas the Younger (q. v.), Gautier (q. v.), Janin (q. v.), Paul de Kock (q. v.), Alphonse Karr (q. v.), Madame Girardin (q. v.) Flaubert, Feuillet (q. v.), Sue (q. v.), &c., in fiction; Cousin (q. v.), Comte (q. v.), Courier (q. v.), Jouffroy (q. v.), Fourier (q. v.), St. Simon (q. v.), St. Marc Girardin (q. v.), Lamennais (q. v.), De Tocqueville (q. v.), Taine (q. v.), Ampère (q. v.), Littré (q. v.), Renan (q. v.), &c., in philosophy, politics, scholarship, and criticism; Hugo, Gautier, De Musset, Murger, Baudelaire, Banville, De Lisle, Deschamps, Dupont, Gérard de Nerval, Barbier, &c., in poetry. The Revolution inspired F. L. with novel audacity and wealth of thought, novel freedom and splendour of style. The French Romanticists, though they loved to select their subjects from the middle ages, did not, like the German Romanticists, become retrograde in politics from a false conception of medieval beliefs and manners of life. Their peculiar grace of style and bizarre fancifulness are still—as in Feuillet—visible in F. L.; but the most recent French fiction is largely characterised by feverish sensationalism and a coarse fondness for glaring colours, licentious plots, and morbid reflections. The French poetry of the 19th c. is rich in lyrical and dramatic masterpieces, is often full of deep passion and stormy ardour, and is generally characterised by a crystal lucidity combined with a sweetness of cadence formerly unknown to the language. See Villemain's *Tableau de la Littér. au Moyen Age* (1857), Fauriel's *Histoire de la Poésie Provençale* (Par. 1846), Littré's *Histoire de la Langue Française* (1867), Geruzez's *Histoire Littéraire de la France* (1865-73), Besant's *Early French Poetry* (1868), Gidel's *Histoire de la Littérature Française* (1875).

French Pol'ish is composed of shellac dissolved in wood-spirit or spirits of wine, and sometimes a little gum-elemi, copal, or mastic is added. The polish is applied to cabinet-work with a rubber, consisting of a woollen rag, gathered into a ball-form, and covered with linen. The rag is slightly soaked with the polish, and before commencing work, the surface of the linen is touched with raw linseed oil. The rubber is plied freely and lightly in short circular strokes till the whole surface has a smooth uniform coat of polish. The linseed oil is finally removed with a cloth moistened with spirits of wine, rubbed very lightly in the direction of the grain of the wood.

French Prot'estant Church. The first seeds of the Reformation in France were perhaps sown by Lefèvre, a teacher in the Sorbonne, who, as early as 1512, turned from the study of the lives of the saints to that of St. Paul's epistles. He it was who infected with his own love for the Bible his pupil Farel (q. v.), and perhaps also Olivetan (q. v.), the former of whom kindled the flame in Switzerland, after helping his master to do it in France, and the latter first translated the Scriptures into French-Swiss, and converted his nephew Calvin (q. v.) from the Romish doctrines. The Sorbonne raised the cry of 'Heresy' against Lefèvre, and drove him from Paris; but the disciples of Luther had meanwhile arrived there, and multitudes 'assumed the liberty of interpreting the Bible for themselves.' Lefèvre retired to Meaux, where, about 1521, he and Farel began openly to preach the new doctrines, and where, about 1523, he published a translation of the New Testament. The clergy were alarmed, and appealed to the Sorbonne, which succeeded in exciting the Parliament against 'the heretics of Meaux.' An interdict was issued against them in 1523, and the congregation there dispersed. Lefèvre found an asylum with the Queen of Navarre; Farel fled to Basel; Pavanes was burnt in 1524, and Berguin in 1529. Calvin dedicated his *Institutes* to François (1529) in a preface imploring his protection for the Protestants, but the only effect of this was to increase the persecution. In 1534 Paris was thrown into excitement by placards which appeared all over the city, violently attacking the mass, the Pope, cardinals, bishops, and monks. Whether this was done by Protestants, or, as some say, by the clergy for a purpose, a rumour went that 'the Lutherans' had laid a plot to burn the city and massacre the Catholics, and soon the cry was raised of 'Death to the heretics.' The order was given to seize all heretics dead or alive, and the prisons were soon crowded. Six of the most prominent were burnt, and an ordinance published for the extermination of the sect. The Waldenses (q. v.) of Provence, who had declared the Protestants their brethren, were treated with indescribable barbarity. The same persecuting policy was pursued by Henri II., who succeeded his father in 1547; but all attempts to exterminate the Protestants were fruitless. In 1555 the first congregation was formed in Paris, and in 1559 a national synod met at the same place, when the F. P. C. was organised, with a Confession of Faith and an ecclesiastical polity essentially Calvinistic.

The same year Henri met his death, and was succeeded by François II., a youth of sixteen, and the husband of Mary Queen of Scots. The uncles of Mary, the Cardinal of Lorraine and the Duc de Guise, were appointed regents, and the Guise faction did their utmost to exterminate the Protestants. Under the leadership of the three brothers Coligny, D'Andelot, and Chatillon, nephews of the Constable Montmorency, they took up arms in desperation to relieve themselves from the tyranny of the Guises; but their plan failed, and many were slaughtered and imprisoned. About this time a third of the population of France were Protestants, and these the choice portion of the nation—the burgesses of the towns, three-fourths of the educated and learned, and half of the nobility, including the King of Navarre and the Prince of Condé. When François II. was succeeded in 1560 by his younger brother, Charles IX., through the influence of the queen-mother, Catherine de Medici, who was jealous of the power of the Guises, the Bourbon party were again received at court; and when the Guises entered into an alliance with Spain, to preserve the balance of power she sought the friendship of the Protestants, and showed them favour. In 1561 an edict of toleration was issued by Parliament to all the presidial courts; but the immediate consequence of this was an outbreak of intolerance, as the

edict was rebelled against wherever the Catholics were more powerful than the Protestants. A second edict, to the effect that the Protestants might meet for worship outside the towns, was no better observed than the first, and a furious and cruel temper was displayed on both sides.

The massacre of a number of Protestants at Vassy by the followers of the Duc de Guise, which was followed by similar outrages elsewhere, was the signal for the outbreak of a civil war which raged, with intervals of peace, for forty years. On the assassination of the Duc de Guise in 1563 a peace was concluded, in terms of which the Protestant worship was to be tolerated in particular places. The war being renewed in 1567 by the Protestants under Condé and Coligny, they suffered a defeat in the battle of St. Denis; and after that the Protestant soldiers, who had hitherto submitted to strict discipline, were guilty of savage reprisals on the Catholics. After a peace of six months, in 1568 the fighting was resumed; the Protestants were again defeated, and Condé fell in the battle of Jarnac. The cause was all but lost, when Coligny suddenly defeated the royal army, and marched on Paris; and a peace on favourable terms was concluded in 1570. The lull was followed by the fearful tragedy of St. Bartholomew's Day (q. v.), which crushed the Church for twenty-six years, during which time only six national synods were held; but it revived after the publication (1598) of the celebrated Edict of Nantes (q. v.), the revocation of which in 1685 by Louis XIV. was fatal alike to France and Protestantism. The new edict enacted that all Protestant pastors should quit France within fifteen days; that the children of Protestants should be educated as Catholics; that Protestants found emigrating should be sent to the galleys for life if men, or imprisoned for life if women. Notwithstanding these penalties, a regular exodus took place. At least 300,000 found their way to other countries; thousands perished or were caught and imprisoned in the attempt; about 1,000,000 were left in the country.

Notwithstanding that there was now no longer a nobility to lead or a clergy to instruct them, and that persecution was unabated, the Protestant cause revived, for the heartless cruelty with which the Protestants were pursued had the effect of exciting much sympathy with them. So galling and atrocious was the persecution in the Cevennes, that in 1702 the inhabitants rose in rebellion. (See CAMISARDS.) They were able to hold their own so well that the Government was glad to come to terms with them, and there followed a period of comparative quiet. The fanaticism of the Camisards was held in check by Antoine Court, called 'the Restorer of Protestantism in France,' by whom the Church was now reorganised *in the wilderness*, and a theological seminary established at Lausanne, which supplied pastors to the Church till the time of Napoleon. Persecution again raged for a time when Louis XV. published (1724) a recapitulation of all the most severe measures passed during the reign of Louis XIV., but from 1730 to 1744 the Church enjoyed comparative quiet, and in the latter year a national synod was convened in Lower Languedoc. This, however, was the signal for the publication of enactments more tyrannical than ever, and a thousand acts of merciless oppression were perpetrated, so that a fresh emigration was the result. A sudden outburst of persecution in Languedoc in 1748 was followed by a period of comparative quietness. Two synods met in 1760, and the ordinary meetings for worship were unmolested. But this calm was interrupted by two wanton executions at Toulouse, which, however, had the opposite effect from that intended, for they excited a feeling of shame and indignation on the part even of many Catholics. Public opinion now gradually became so strong against persecution, that in 1787 the Edict of Toleration was passed by the Assembly of Notables, allowing Protestants to live in France unmolested for their religion, and to marry, baptize, and bury according to their own forms. In 1789 the Constituent Assembly declared 'all citizens equal in the eye of the law.' Under Napoleon as First Consul, the Catholic clergy and Protestant pastors were on an equal footing, with the one exception of state support, which the latter did not receive. But as this left the Protestant Church comparatively independent, along with supplementary support to the pastors, he gave it a new constitution, placing it entirely under the control of the state. On the restoration of the Bourbons in 1815, an attempt was made to renew the old persecution; indeed, 'another Bartholomew' was planned, and was near being executed. The second revolution in 1830 again placed all religions on an equal footing, and in spite of petty persecution by the Jesuits, Protestantism increased. In 1838 the Reformed (Calvinistic) Church had about 460 pastors; the Lutheran about 260. From 1659, when Louis XIV. intimated that such meetings would no longer be permitted, no synod had met with the sanction of the state till 1872. An attempt at one in 1848 was a comparative failure. The proposal to draw up a Confession of Faith was negatived, whereupon those who wished it seceded and formed themselves into the Union of the Evangelical Churches in France. Since no Confession was included in the constitution provided for the Church by Napoleon in 1802, and the old one was then obsolete, the Church had practically been without one from that time. Accordingly the conservative party in the synod of 1872 wished to endow the Church with a genuine Confession, and by a narrow majority succeeded in carrying their point; but its extremely general terms is an immense departure from the Predestinarian theology of the old one. Now that Alsace and a part of Lorraine, where a numerous Lutheran population had gathered, are severed from France, there do not remain in it above 800,000 Protestants, of whom 70,000 to 80,000 are Lutherans. See De Félice's *Hist. des Protestants de France* (Par. 1850), and MM. Haags' *La France Protestante* (Par. 1847-59).

French River, in the Dominion of Canada, province of Ontario, is an outlet of Lake Nipissing, and flows into Lake Huron after a course of 55 miles, part of which, through bare rock, looks like an artificial cutting. It is impeded by many rapids, but forms a channel for the fur trade of the Red River settlements.

Frere, John Hookham, was born in London in 1769, entered Parliament in 1796, and became Under Secretary of State for Foreign Affairs in 1799. He was one of the founders of the *Quarterly Review*, and the author of *Translations of Several Plays of Aristophanes* (1840), *Theognis Restitutus* (1842), and other writings, chiefly humorous. In 1808 he was appointed Minister to Spain, married the Countess of Erroll (1816), and removed to Malta, where he died at Pieta, 7th January 1846. His works were published with a memoir in 1872.—**Sir Bartle Edward F.**, nephew of the preceding, was born in 1815, educated at Haileybury College, and entered the Indian Civil Service in 1834. He was made British Resident in Scinde in 1856, and Chief Commissioner in 1860, and for his conduct during the Mutiny twice received the thanks of Parliament and was created a K.C.B. From 1862 to 1867 he was Governor of Bombay, and in the latter year was made a K.G.C.S.I., and returned to England, where he became Vice-President of the Royal Geographical Society. As special British commissioner he brought about the abolition of slavery by the Sultan of Zanzibar in 1873. He was sworn a member of the Privy Council on his return, and appointed Governor of Cape Colony in 1876. His writings include *Pandurang Hari, or Memoirs of a Hindoo* (new. ed. 1873), and *The Impending Famine in Bengal, and how to Prevent Future Famines in India* (1874).

Fre'ron, Élie-Catherine, a French critic and jealous champion of monarchy and the Christian faith against the tendencies of the time, was born in 1719 at Quimper. He is best known by his critical journal, which ultimately appeared under the name *L'Année Littéraire*, and which he conducted from 1746 till his death, 10th March 1776. F.'s fame is less due to his own talents than to his perpetual feud with Voltaire and the Encyclopedists, maintained on both sides with the intensest bitterness.

Fres'co (Ital. 'fresh'), a method of decorative painting executed upon wet or *fresh* plaster with raw pigments mixed with water or hydrate of lime. In drying, the colours are incorporated with the plaster, and are thereby rendered as durable as itself. The *intonaco* or F. ground is composed of two parts fine river sand and one part lime. It is floated on about one-eighth of an inch thick, and in quantities that the artist can overtake at one painting. A copy of the F. design on paper is laid on the wet plaster, and the outlines are indented through by means of a bone stylus. The colours, chiefly simple earths, are then applied with great breadth and freedom, brushes of hogs' and other hair being used. No colours of vegetable origin, and few compounded mineral pigments, withstand the chemical action of lime. To produce a successful F., considerable artistic and technical skill and experience are required. A design of masterly com-

position and careful drawing, the selection of permanent colours, and rapid work without retouching, are the chief essentials. A pure atmosphere is necessary for the permanence of a F., damp is fatal to it, and smoke and the products of the combustion of gas and coal are also very injurious. The failure of many of the experiments in F.-painting made in England of late years, in the Houses of Parliament and elsewhere, is traceable partly to climatic and other influences, and partly to the use of unsuitable pigments.

F.-painting is a most ancient art. Remains of it are still found in Egypt, and among the Romans it was extensively practised. Ancient examples of this mode of painting are to be seen in Pompeii, Rome, and other places. The art attained perfection on the revival of the arts in Italy. The highest pictorial efforts of Michael Angelo, Raphael, Giotto, Correggio, and others, are executed in F. in churches and palaces in Italy. After falling into disuse the art has been revived in Germany and in England.

Fresco Secco is distinguished from the foregoing, *buon* F., or true F., by the painting being executed on dry plaster, which is moistened with lime-water before the colours are applied. Many of the wall paintings of the ancients were executed by this method, and in Italy at the present time it is commonly practised.

Fresh'-Water Herr'ing. See CORECONUS.

Fresh'-Water Muss'el, a popular name applied to various kinds of Lamellibranchiate *Mollusca* inhabiting fresh-water streams and lakes. The genera *Unio* and *Anodonta* contain examples. This mussel is not to be confused with the true marine mussel, which belongs to an entirely different family—that of the *Mytilidæ*. The F.-W. M. has a shell generally equivalve, with a large external *ligament* used for opening the shell. The anterior hinge teeth are thick and striated, the posterior teeth being laminated in structure or wanting. The mantle-lobes are united between the (*siphonal*) apertures, and the foot, which is large and compressed, has the power in the embryonic state of secreting a *byssus* or 'beard,' such as is seen in the marine mussels. Of the genus *Unio* itself, the *U. littoralis* and *U. pictorum* are familiar species. The *U. margaritifera* produces pearls which, especially those found in Scotch rivers, are sometimes of large size and of considerable value. The swan or river mussel (*Anodonta cygnæa*), the *A. ensiformis*, and the *A. angulata* are examples of the second genus.

Fresh'-Water Stra'ta, in geology, are deposits which have been formed by lakes, rivers, or fresh water filtering into caverns. As a rule, they are of small extent compared with marine deposits, but they are important as indicating the presence of land, and frequently the nature of the fauna and flora of inland regions.

Fres'nel, Augustin Jean, a distinguished French mathematician and physicist, was born at Broglie (Eure), 10th May 1788. In his seventeenth year he entered the École Polytechnique, where he gained high distinction. He was afterwards appointed engineer to the department of Vendée, and later to that of Drôme, where he stayed till 1815. About the year 1814 he began the study of light, his researches in which in 1827 obtained the Rumford medal of the Royal Society of London. F. died at Paris, July 14, 1827. Though later in attacking the subject of light than the celebrated Young, his superior power of mathematical analysis enabled him to far outstrip that distinguished philosopher, and to establish still more the probability of the truth of the undulatory theory of light. The simplicity of his explanations of reflection, refraction, diffraction, and polarisation is itself a powerful argument in favour of his theory. He also greatly improved the apparatus for lighting lighthouses. His memoirs are published in the *Annals de Physique et de Chimie* and in the *Mémoires de l'Académie des Sciences*, which contain an *Éloge* on F. by Arago.

Fresnill'o, a town of Mexico, state of Zacatecas, on a branch of the Santiago, 30 miles N.W. of Zacatecas. It has a good mining school, and in the vicinity are rich copper and silver mines. Pop. 7015.

Fret, in heraldry, is a figure in which two lines, interlaced with a mascle, cross the shield transversely. The shield is said to be *fretty* ('broken,' from Lat. *fractus*) when it bears several such lines.

Freu'denstadt ('town of joy'), a town of Würtemberg, Germany, in the circle of the Black Forest, near the Murg, 40 miles S.W. of Stuttgart. It has some cotton-spinning, weaving, and smith-work, and a trade in wood, cattle, and fruit. Pop. (1872) 5145. F. was founded in 1559, and its first inhabitants were Lutheran refugees from Austria.

Frey'a, a Teutonic goddess, daughter of Niörd, and sister of Freyr, young and beautiful, was the wife of Odin, who deserted her, and the goddess of love but also of death. That she was originally the same as *Frigg*, another wife of Odin, is doubtful. The latter, however, was known to the Old English, Frisians, and other Low Germans as *Frea* and *Fria*, and her name is still preserved in *Friday*, originally *Frigdaeg* (Old Ger. *Frîatac*).

Freyr, son of Niörd, a Teutonic god, worshipped in early times by the Swedes as the supreme deity. His temple was at Upsala and his festival at Yule. He was wise and peaceful, ruler of sea and air, and the giver of fertility to earth and to mankind.

Frey'stâdl (Hung. *Galgocz*), a town of Hungary, on the banks of the Waag, 84 miles N.W. of Pesth, and nearly opposite the fortified Leopoldstadt. It has a castle, a tower of supposed Turkish origin, some manufactures of wooden articles, and a trade in cattle. Pop. (1869) 6098.

Frey'tag, Gu'stav, called by his admirers 'the father of the modern German novel,' and known also as a poet and journalist, was born 13th July 1816, at Kreuzburg, in Silesia. After some years spent as a *docent* in the University of Breslau, he became, in 1848, editor of the journal *Die Grenzboten*, with which he was connected till 1870. He first acquired fame by his dramas *Valentine* (Leips. 1847) and *Graf Waldemar* (Leips. 1848). In 1855 appeared the successful comedy *Die Journalisten*, and in 1859 the antique drama *Die Fabier*. F.'s earlier novels are thoroughly modern in subject and spirit. *Soll und Haben* (1855), translated into English under the name *Debit and Credit* (1858), is a vigorous, truthful, and lively picture of the life in a German provincial town, and thoroughly deserves its great popularity (in 1871 the 16th edition appeared). Other works of F. are *Neue Bilder aus dem Leben des Deutschen Volkes* (Leips. 1862, Eng. trans. 4 vols. 1862-63), and *Die verlorene Handschrift* (1864, Eng. trans. 1865), which draws on university circles. In the novels *Bilder aus dem Deutschen Vergangenheit* (4 vols. 6th ed. 1871) F. has gone for his subjects to mediæval German history, and has treated them with patriotic spirit, deep insight, and artistic skill.

Fri'ar (Fr. *frère*, Lat. *frater*, 'brother') is a name common to members of all religious brotherhoods, but generally confined to the Mendicant Orders, which were reduced by Leo X. in the Council of Lyon (1272) to four—the Dominicans, Franciscans, Carmelites, and Augustinian Eremites. The Franciscans (q. v.), called by their founder *Fraterculi*, or *Fratres Minores* (Minor Friars), got the name in England of *Grey Friars*, from the colour of their habit. The Dominicans, first called *Preaching Friars*, were afterwards called *Major Friars*, in contradistinction to the Franciscans, and in England *Black Friars*. The Carmelites were the *White Friars*. In a more restricted sense still, F. is applied to the members of these orders who are not priests. Those in priest's orders are called Fathers.

Friar's Bal'sam (*Tinctura benzoini compositus*), sometimes called *traumatic B.*, is a compound of benzoin, 8 parts; prepared storax, 6; balsam of tolu, 2; socotrine aloes, 1½; and rectified spirit, 80; prepared by maceration and filtration. It is given internally for chronic cough, and is applied externally to languid ulcers, cuts, and wounds. See BENZOIN.

Fric'tion is the resistance to relative motion experienced at the surfaces of two portions of matter in contact. In the case of the sliding of solids, the laws of F. established by experiment are very simple, and require the mere statement for their comprehension. 1. F. is proportional to the pressure; 2. F. is independent, *ceteris paribus*, of the areas in contact; 3. F. is independent of the relative velocity. The same laws hold approximately for rolling bodies, except that in certain instances increase of velocity increases the F., an effect due no doubt to the *sliding* motion which must be present when the velocity is greatly increased. The resistance experienced by a solid moving through

a fluid is due in great measure to *fluid F.*, which depends upon the viscosity of the fluid. On account of this viscosity, vortices or eddies are generated in the fluid when a solid moves through it, and this vortex motion necessitates the disappearance of a portion of the kinetic energy of the solid. It is thus apparent that the study of the phenomena arising from F. must hold an important place in many questions of practical moment. As examples, the gradual retardation of the earth's diurnal motion through the loss of energy by tidal F., and the diminution of the period of revolution of Encke's comet due to the presence of a resisting medium may be cited. In all cases, F. acts against the motion; and a definite quantity of energy must always be expended in overcoming it. The equivalent of this lost energy is to be found in the heat ultimately generated. Electrical effects also are known to accompany the rubbing of bodies together. Delicate experiments, however, have shown that contact of heterogeneous bodies and separation are sufficient without F. to generate electricity; and this suggests that F. may, partly at least, be due to attractive force which is called into action when separation is effected between the two oppositely-charged portions of matter originally in contact. The *coefficient of F.* for any two bodies is the ratio of the F. to the pressure, and is an important mathematical *constant* in the study of statics.

Frid'ericia, originally **Fred'eriks-Odde**, a fortified seaport of Denmark, on the E. coast of Jutland, occupies the peninsula of Skandse-Odde. It is the port where are collected the dues of the Little Belt, and it has twenty-two factories and an active manufacture of tobacco. Pop. (1873) 7186.

Fried'land, a small town of E. Prussia, on the Alle, 26 miles S.E. of Königsberg, notable as the scene of the victory of Napoleon I. over the Russians under Bennigsen, which led to the peace of Tilsit, 14th June 1807.—Another F., in Bohemia, on the Wittich, is the capital of a district, and gave the title Duke of F. to the great Wallenstein. Pop. (1869) 4260.

Friedland, Valentin, an eminent educationist, was born at Trotzendorf in Upper Lusatia, 14th February 1490, and from this place he derived his popular surname. After a course of study, chiefly memorable for the knowledge of Greek which he acquired, he embraced Lutheranism, formed at Wittenberg the acquaintance of Luther and Melancthon, and, according to report, placed himself in the service of a converted Jew for two years, on the understanding that as a salary he should obtain lessons in Hebrew. He is memorable for the success which attended his efforts as rector of the Gymnasium at Goldberg in Silesia, to which he was appointed in 1523. Pupils flocked to it not only from the surrounding district, but from neighbouring countries such as Poland, Austria, and Hungary. F. died at Liegnitz, April 26, 1556. See Pinzger's *Valentin F., genannt Trotzendorf* (Hirschberg, 1825; Breslau, 1856).

Fried'rich, a common name of German rulers. Some of the more famous are here noticed.

Romano-German Emperors.—**Friedrich I.**, surnamed *Barbarossa* ('red-beard'), the second of the Hohenstauffen line, was born in 1121, perhaps at Waiblingen. He was the son of Duke Friedrich of Swabia, and grandson of Emperor Heinrich IV. He succeeded his uncle Konrad III. in the imperial dignity in 1152, being crowned at Aachen by Arnold, Archbishop of Köln. Connected himself through his mother, Judith of Bavaria, with the Welf party, F. at once began a policy of conciliation. The quarrel of Knut V. about the Danish throne and the claims of Heinrich the Lion to Bavaria were settled; aid was promised to the Pope against Arnold of Brescia. It required some hard fighting to vindicate his authority in Milan, but in 1155 he opened the ancient *comitia* of the duchy at Roncaglia, and was crowned at Pavia. There was more fighting at Rome, where Arnold was burned alive. A difference now rose between F. and the Pope, Adrian IV., about the lands of the Countess Matilda of Tuscany, bequeathed to the Holy See, but claimed by F. as feudal suzerain. On his return to Germany, F. found ample employment in stopping the brigandage of the *burggrafen*, and in removing some of the heavier restrictions on commerce. He repaired the finances, controlled the dukes, exalted the central power by multiplying nobles of the second rank, afterwards the 'College of Princes,' and tried to supersede local and conflicting Teutonic customs by the Lombard feudal code, and the civil law which the new school of glossatores was now teaching in the great universities. To the great towns, *e.g.*, Köln, Trier, Mainz, Worms, Speyer, Nürnberg, &c., he gave municipal franchises and independent jurisdictions, which made them a counterweight to the local oligarchy. From 1158 to 1162 there was war in Italy, in which F., trying to impose an absolute government by Podestas of his own nomination on the towns which had democratic consular institutions, naturally roused them into fierce revolt. As an instance of the extent of the imperial power at the time, it may be mentioned that at the Diet of Besançon F. invested Waldemar with the royal dignities Denmark, Sweden, and Norway, and gave to Raymond of Provence a portion of the kingdom of Arles, and soon after compelled the Pope to canonise Karl the Great. The Lombard League of cities was now, however, gathering strength, and after several campaigns F. at last was defeated by the Milanese at Legnano, 29th May 1176, and by the good offices of Sebastian Ziani, the Doge of Venice, a meeting of peace was arranged between Pope Alexander and the Emperor, where the latter confessed the papal supremacy, the Antipope Calixtus III. retiring. In 1183 the more durable peace of Constance was entered into, which for some time was the guarantee of freedom in N. Italy. The news that Saladin had taken Jerusalem (1189) determined F. to lead a crusade to the Holy City. Crossing the Hellespont with 100,000 men, he obtained a great victory at Iconium (1190). Soon after he was accidentally drowned while bathing in the Cydnus. In the midst of his vast political and military activity F. found time to patronise the *Minnesingers*. It is an old German legend that F. still lives in a limestone cave in the Untersberg (Salzburg), whence he will issue with his crusaders and re-establish the golden age of Germany. When the German Empire was revived in 1871, men said the old legend had come true. See Prutz's *Kaiser Friedrich I.* (1871).—**Friedrich II.**, grandson of the preceding, was born at Jesi, in the March of Ancona, 26th December 1194. His father died in 1197, and his mother, Constance of Sicily, committed to Pope Innocent III. the education of her son. He became an accomplished scholar. The old description of him was—'Armorum strenuus, linguarum peritus, rigorosus, luxuriosus, epicurus, nihil curans vel credens nisi temporale: malleus Romanæ ecclesiæ.' In 1212 he married Constance of Aragon, and two years later was crowned King of the Romans at Aachen. The same year Innocent III., who had in 1201 published his celebrated brief to the effect that the empire really belonged to the Church, was succeeded by Honorius III., who at once insisted on F. performing his promise to make a crusade. The latter was, however, too much engaged with the rebellious Palatinate and the town of Brunswick to leave Europe, and by a series of ingenious excuses he delayed until 1220, when, after crowning his son Heinrich King of the Romans, he came to Rome, where he was himself crowned by the Pope, whose suspicions were allayed by the concessions of jurisdiction and exemption which F. had made to the ecclesiastical princes of the empire. For seven years F. governed the empire from Italy, or rather Sicily; he cultivated art and letters, founded the University of Naples, and his chancellor, Petrus de Vineis, published a code of laws. After his marriage with Jolante, daughter of Jean de Brienne, titular King of Jerusalem, F. was in 1227 driven by the new Pope, Gregory IX., to fulfil his promise of a crusade. By an injudicious attempt to curtail the freedom of the towns in N. Italy he resuscitated the old Lombard League, and by his reluctance to start for Palestine he drew down on himself the ban of excommunication. The angry letters which he now sent to Rome were the boldest which the world had yet seen. He calls the Pope an insatiable leech, who, unlike Christ, prefers war instead of peace, and amasses wealth by unjust means instead of remaining poor like Peter. He even entered Rome with a body of Arabian troops. The crusade consisted in a treaty or *mosapha* between F. and Kamel, the Sultan of Egypt, for a ten years' joint occupation of the Holy City by Christians and Mohammedans. Disputes with the Pope, the Lombards, and his son Heinrich fill up the period till 1235, when F. dethroned Heinrich, made his son Konrad King of Germany, and married Isabella of England, sister of Henry III. The victory of Corte Nuova on the Oglio (26th and 27th November 1237), in which Milan lost the *caroccio*, or standard-chariot, made the chief Lombard cities submit, and so alarmed Gregory that he again excommunicated the Emperor, alleging that he blasphemed, that he called Moses and Christ impostors, and denied the possibility of a birth from a

virgin. In spite of F.'s services to Christendom in turning back the Mongol invader at Olmutz (1241), the new Pope, Innocent IV., continued the traditional hostility, and finally declared him to be deposed, and all his subjects freed from their allegiance. This encouraged Heinrich Raspe of Thuringia and Willem of Holland successively to declare themselves emperor. They were both defeated, but soon after F. died at Fiorentino, 12th December 1250. See Shirrmacher's *Kaiser F. II.* (Gött. 3 vols. 1859–64), and Winkelmann's *Geschichte Kaiser F.'s II. und seiner Reiche* (Berl. 1863).—**Friedrich III.**, the Pacific, twenty-ninth Romano-German emperor, the son of Duke Ernst of Styria, was born at Innsbruck, 21st September 1415. He succeeded to the imperial throne in 1440. He allowed Sforza to establish himself at Milan. The death of his ward Ladislaus brought him Lower Austria, but his expectations of Bohemia and Hungary were disappointed by Podiebrad and Corvinus. F. studied botany, alchemy, and the stars, while the Turks were advancing through Carniola to Salzburg. At last Bohemia and Hungary began war against him. He was obliged to renounce many of his possessions and claims, and retired from Vienna to the Netherlands, where his son Maximilian, by Eleanor of Portugal, had married Maria of Burgundy. The death of Corvinus in 1490 brought back Lower Austria, but Hungary fell to Podiebrad. After crowning Maximilian King of the Romans, F. died at Linz, 19th August 1493. The only good or vigorous work which he did in this stirring period of Hussite heresy, Turkish invasion, early renaissance, and the decay of feudal power, was the formation of a peace league among the Swabian cities. See Chmel's *Geschichte Kaiser F.'s IV.* (Hamb. 2 vols. 1840–43).

Electors of Brandenburg.—**Friedrich Wilhelm**, Elector of Brandenburg, known as the 'great Elector,' was born at Köln, on the Spree, February 6, 1620, and succeeded his father, Georg Wilhelm, as Elector of Brandenburg in 1640. In 1641 he entered into a treaty of neutrality with Sweden, and in 1644 reannexed Kleve and the county of Mark to his dominions by making an armistice with Hessen-Kassel. He devoted himself successfully to strengthening his army, by turns aided Poland and Sweden when war broke out in 1655, and entirely freed Prussia from the sway of Poland, on which it was till then dependent. In 1672 he formed an alliance with the Dutch Republic, but on the French invading the Netherlands, was crippled in his efforts to oppose them by the jealousy of the Austrians, and in 1673 made a treaty with France, breaking off his league with the Dutch. In 1675 he defeated the Swedes, who had invaded his territory, at Fehrbellin, but being unsupported by the other German rulers, was forced to yield to the French demands, and by the treaty of St. Germain, 1679, to restore the land which he had won from Sweden. He afterwards brought about an armistice between France and Germany, and sent 8000 men to aid Austria against the Turks. F. did much to consolidate and improve his possessions. On the revocation of the Edict of Nantes he afforded protection to 20,000 French refugees, who gave a great impulse to the industries of Prussia. He enlarged Berlin, and founded the University of Duisburg. He died at Potsdam, April 29, 1688. See Orlich's *Geschichte des Preuss. Staats im 17ten. Jahrh.* (3 vols. Berl. 1838–39); Förster's *Geschichte F. Wilhelm's des grossen Kurfürsten* (4 vols. Berl. 1855); Erdmannsdörffer's *Urkunden und Actenstücke zur Geschichte des Kurfursten F. Wilhelm von Brandenburg* (Berl. 1864 *et seq.*); and Peter's *Der Krieg des grossen Kurfursten gegen Frankreich* (1870).

Kings of Prussia.—**Friedrich I.**, King of Prussia, son of the Great Elector, was born at Königsberg, 22d July 1657. He succeeded his father in the Electorate of Brandenburg in 1688, and was a firm adherent of William of Orange and the other allies against Louis XIV. In 1700 he procured the title King of Prussia from the Emperor, whom, in return, he promised always to support in the Diet and in the field. In 1701 he placed the crown on his own head at Königsberg, and continued to oppose France until his death, February 25, 1713. He founded the order of the Black Eagle, the University of Halle, and the Royal Academy of Berlin, a city which he greatly beautified. Carlyle describes him as 'a perfect gentleman, and a courageous and high though thin-skinned man.'—**Friedrich Wilhelm I.**, King of Prussia, son of Friedrich I., was born August 2, 1688, married Sophia-Dorothea, daughter of the Elector of Hanover—afterwards George I. of England—in 1706, came to the throne in 1713, and devoted himself to improve the finances, and above all to strengthen the army of Prussia. He opposed Charles XII. of Sweden, interfered to protect the Protestants in adjoining states, and did much to develop the industries of his kingdom. He was ludicrously fond of tall soldiers, and spared no pains to procure them for his forces. He was a wise, vigorous monarch, but a man of coarse tastes and almost no culture. He died May 31, 1740, leaving Prussia with an army of 70,000 men, whom he had collected and drilled with unflagging assiduity. Probably Carlyle was the first to look wisely into his real character, and to detect the worth that lay beneath the transcendent rudeness and brutality of his manners.—**Friedrich II.**, the Great, the ablest ruler of the 18th c., son of the preceding, was born January 24, 1712. When 'one of the prettiest, sprightliest lads,' he quarrelled bitterly with his father, who thwarted his tastes for poetry and music, and forbade him to receive any other than a military training. The dissension increased, and F., taken when trying to fly to the court of his uncle the King of England, was kept in strict confinement, his father, it is said, having at one time been only deterred from sentencing him to death by the intercession of the Swedish and Polish kings. In 1733 he was brought back to court to marry the Princess Elizabeth-Christina, daughter of Ferdinand Albrecht, Duke of Brunswick-Bevern, and lived in retirement at Rheinsberg, where he wrote his *Anti-Machiavel* and other works, associated with *literati* and corresponded with scholars, especially with Voltaire, until on his father's death he became king in 1740. Taking advantage of the death of the Emperor Karl VI., he demanded from Maria Theresa the Silesian principalities of Jägerndorf, Liegnitz, Brieg, and Wohlau, to which the house of Brandenburg claimed a reversionary right. The demand being refused, F. entered Silesia and defeated the Austrians near Mollwitz, 10th April 1741. France and Bavaria now joined him, and after his victory at Czaslau (17th May 1742) the first Silesian war ended, Prussia obtaining Upper and Lower Silesia. After the second Silesian war, in which he defeated the Austrians and Saxons at Hohenfriedberg (4th June 1745) and Sorr (30th September), Hennersdorf (23d November) and Kesselsdorf (15th December), F. devoted himself during the eleven years of peace which followed to bettering the condition of Prussia, organising his army, and likewise to occasional literary labours, writing his *Mémoires de Brandenbourg*, and his poem *L'Art de la Guerre*. Hearing of an alliance between Austria, Russia, and Saxony, and dreading to lose Silesia, in 1756 F. entered Saxony, and the third Silesian or Seven Years' War (q. v.) began. Opposed by France, Austria, Russia, Saxony, with only England as an ally, F. triumphed signally over his enemies. Of the sixteen great battles which F. and his generals fought, he was victorious at Lowositz (1756), Prag, Rossbach, and Leuthen (1757), Krefeld and Zorndorf (1758), Liegnitz and Torgau (1760), and Freiberg (1762). When the war ended by the peace of Hubertsburg (1763), F. had shown a military genius previously unequalled in modern history, and had laid the foundation of a united Germany. Henceforth Prussia was recognised as a great force in European politics. F. now strove to lighten the taxation of his subjects, practised the strictest economy, founded various useful institutions, opened his magazines to aid the agricultural population, and established an excise on the French system. In 1772 he took part with Russia and Austria in the partition of Poland (q. v.), and by the treaty of Teschen (1779) brought about the union of Franconia with Prussia. In 1785 he formed the confederation of the German princes, and in August 17, 1786, died at Sans Souci, leaving Prussia in a flourishing financial condition, with a population raised from 2,240,000 to 6,000,000, an army of 200,000, and a greatly extended territory. F.'s moral character has many dark blemishes—he was dishonourable, vindictive, and callous, the somewhat fantastic sensibility of his youth hardening into icy cynicism, into an arch contempt for humanity which was embittered by his Voltairian creed. On the other hand, his intellectual breadth and keenness, his foresight and adroitness, his sagacious promptitude and marvellous firmness, his dazzling administrative and military genius are unexcelled in history. In all likelihood he was unaware of the mighty results of his policy, he probably looked merely to the founding of a strong, independent Prussia. In this he succeeded, but his career was pregnant with other consequences. He was a great leader of the movement which changed the old to the new Europe. His campaigns put an end to the dynastic and per-

sonal strifes which had racked Europe for a century before the Seven Years' War. He checked the Jesuits, who were strangling freedom; led the way in forwarding religious toleration; made international, not personal, relations the ground of war; and gave the first example to modern times of a new type of monarchy, which practised thrift, exercised a regal supervision over the kingdom, and favoured industry and the people's welfare, as opposed to the essentially mediæval despotisms of Austria and France. He strove to make Berlin an academic centre, and was a zealous admirer and student of French literature, though blind to the merits of the rising school of German authors. An edition of his works was issued by the Berlin Academy (1846-51). See Kolb's *Das Leben F.'s des Einzigen* (4 vols. Speyer and Leips. 1828); Förster's *Leben und Thaten F.'s des Grossen* (2d ed. Leips. 1842), and *F. der Grosse* (4 vols. Berl. 1860); Kugler's *Geschichte F.'s des Grossen* (Leips. 1860); and Carlyle's *History of F. II.* (4 vols. Lond. 1858-65).—**Friedrich Wilhelm II.**, nephew of the above, was born September 25, 1744. A coolness between him and the great Friedrich was dispelled by his courage at the battle of Neustädtel, in the war of the Bavarian succession (1778), and he came to the throne in 1786. He made various aimless and costly political interferences, declaring war with Holland and the French Republic, abandoned his uncle's wise neutrality in theological questions, squandered his revenues, indulged unworthy favourites, and shared in the second partition of Poland in 1793. He died November 17, 1797, leaving Prussia with additional territory, but with a debt of 22,000,000 thalers. See F. von Cölln's *Vertraute Briefe*, &c. (6 vols 1801-9).—**Friedrich Wilhelm III.**, eldest son of the preceding, was born August 3, 1770, married the Princess Louise of Mecklenburg-Strelitz in 1793, and became king in 1797. He began his reign by retrenching the public expenditure, organising the finances, and abolishing monopolies. During the Napoleonic struggle he at first sought to remain neutral; then became an ally of France, receiving in reward Hildesheim, Paderborn, and Münster; and at length, after vacillating between Russia and Napoleon, who treated him with open contempt, declared war with France. The Prussians were defeated at Jena, Eylau, and Friedland, and by the treaty of Tilsit (1807) he was stripped of three-fourths of his dominions. He laboured vigorously, however, to improve the fraction of Prussia which remained to him, and passed several wise decrees, framing the constitution anew, removing the privileges of the nobles, and promoting free trade. To this period of political degradation also belongs the reorganisation of Prussia's educational system, which has raised her to the foremost place among civilised nations. After the French retreat from Moscow, F. again proclaimed war against Napoleon, who had continued to shower insults upon him while striving to restore his humbled kingdom. The Prussians were at first checked in the field, but afterwards had the largest share in the victory of Leipsic (1813). After the fall of Napoleon, F. recovered all his former and other additional territories. He divided Prussia into ten provinces, each ruled by an *ober-präsident*, enacted that every man must serve in the army, developed commerce by founding the *Zollverein*, and forwarded industry generally, but broke his promise to create a new constitution, and showed himself hostile to Liberal principles. He died June 7, 1840. See Eylert's *Characterzüge und historische Fragmente aus dem Leben des Königs von Preussen F. W.* (3 vols. Magdeb. 1842-46).—**Friedrich Wilhelm IV.**, eldest son of F. W. III., was born at Berlin, October 15, 1795. While a youth he was noted for his accomplishments, and served in the campaigns of 1813-14. After peace was made, he returned to artistic pursuits, and visited Paris and Italy. He began to reign in 1840, and at first raised bright hopes by promising reform and seeming to sympathise with Liberalism. But he soon discarded his Liberal counsellors, and pursued a retrograde and absolutist policy, until, in 1848, his guards being beaten in a street fight with the Berlin populace, he was forced to swear that he would grant a new constitution. This promise he never kept. He prosecuted the Liberals and favoured the Ultramontanes, besides being greatly under the influence of Russia. F. W. at last became partly insane, and in 1857 Prince Wilhelm of Prussia became regent, the king thenceforth living in retirement until his death at Sans-Souci, January 2, 1861. See Varnhagen's *Tagebücher* (14 vols. 1861-70), and his *Blätter aus der Preuss. Gesch.* (5 vols. 1868-69.) There were twice attempts to murder F. W.—in 1844 by Tschech, a burgomaster, and in 1850 by Sefeloge, a discharged soldier.

Friedrich, Karl Nikolaus, imperial prince of Germany, eldest son of Prince Karl, second brother of the emperor, was born March 20, 1828, commanded in the Danish war of 1864, led the first army through Saxony against Austria, and won the battle of Königgratz with the aid of the Crown Prince in 1866. In the Franco-Prussian war he commanded the second German army, defeated General Froissart at Speichern, and invested Metz until Bazaine capitulated. He then drove back the Army of the Loire, retook Orleans, and forced General Chanzy to retire. F. was made a field-marshal October 28, 1870.

Friedrich Wilhelm, Crown Prince of Prussia, and son of King Wilhelm I., was born 18th October 1831. He took part in the Slesvig-Holstein war (1864) under Wrangel, and in the war with Austria (1866) received the command of the second army, and fought at Nachod, Trautenau, Skalitz, Soor, Schweinschädel, Königinhof, and Königgratz. In the Franco-Prussian war of 1870 he was in command of the third army, and took part in the battles of Weissenburg, Wörth, and Sedan.

Friedrich Wilhelm, Duke of Brunswick, son of Karl Wilhelm Ferdinand, was born October 9, 1771, accompanied the Prussian army into France in 1792, was made commander of a regiment, and in 1806 was taken prisoner along with Blucher at Lübeck. His rights to the Duchy of Brunswick being set aside by Napoleon, he continued to fight in Bohemia until the Austrians were totally overthrown, when he executed a masterly retreat with 1500 men, defeating Reubel with 4000 troops at Aelper (1809), and sailed for England, where he was received with enthusiasm. Along with his men, the 'Black Brunswickers,' he joined the English service, fought in Spain, and fell bravely at Quatre Bras, June 16, 1815. His biography was written by Spohr (Brunsw. 1861).

Friend'ly or **Ton'ga Islands,** a group to the E. of the Fiji Islands, in the Pacific Ocean, between lat. 13°-25° S. and long. 172°-177° E. They are over 150 in number, the smaller ones being of coral formation, the larger ones of volcanic. Some 30 are inhabited, and the total population amounts to 25,000. They have few native animals, but are richly productive in yams, sweet potatoes, bread-fruits, cocoa-nuts, &c. The largest island is the Tongatabu or Sacred Tonga, with 8000 inhabitants. The group was discovered by Tasman in 1643, received its name from Cook, and was first visited by missionaries in 1797. A Wesleyan mission was founded here in 1827, and King George, the chief native ruler in the group, embraced Christianity.

Friendly Societies. See BENEFIT SOCIETIES.

Friends, Society of, is a sect of Christians better known by the name of Quakers. The name is derived from their practice of addressing each other as 'Friend,' rather than by any title. The history of the origin of the sect is simply a history of the life of George Fox (q. v.). At the outset his followers exposed themselves to imprisonments and other punishments by their rude and fanatical conduct. For the first few years they seem to have interrupted public worship in the parish church wherever they opened their missions—the example having been set by Fox himself—sometimes in a most annoying and indecent manner. They spoke in a most offensive way against what they called the abominations of all existing Churches. Some even desecrated the Lord's Day, as a legal ordinance which ought to be treated with contempt. But, on the other hand, their errors were magnified, and their indiscretions punished as outrageous crimes. In many cases the peculiar garb and mode of speech, proclaiming the simple fact of their being Quakers, were of themselves a sufficient condemnation. It is a sad proof of the intolerance of the age that they were treated worst of all under the Commonwealth by the Puritans, who themselves had just been relieved from the tender mercies of the Star Chamber and the Court of High Commission. Indeed, when some of them betook themselves to New England, expecting to receive at least indulgence from the Puritans who had fled thither on account of persecution for conscience' sake, they were persecuted with an intolerance which has no parallel but in the annals of the Inquisition. In 1658 a law was passed 'that for the first offence (*i.e.*, of being a Quaker), if the offender were a male, one of his ears should be cut off, and he be kept at work in the house of correction till he should be sent away on his own charge. For the second, the other ear, and be kept in

the house of correction as aforesaid. If a woman, to be severely whipped and kept as aforesaid; and for the second offence, to be dealt withal as the first. And for the third, he or she should have their tongues bored through with a hot iron, and be kept in the house of correction close at work till they be sent away on their own charge.' This law, as a preventive measure, having proved an utter failure, another Act was passed the same year, which condemned Quakers to banishment, and inflicted the penalty of death if they revisited the colony. Under this Act many Quakers suffered exile, and some were put to death.

In England a paper was laid before Parliament in 1659, in which they recount their sufferings, from which document it appears that during the preceding six years about 2000 had suffered in their goods or persons. Some of their sufferings, it must be confessed, were the fruit of their own extravagance. After the Restoration in 1660, 700 Quakers were released from various prisons. The king was prepared even to grant them the free exercise of their religion, when Venner's insurrection happened. The Quakers were confounded with the Fifth Monarchy Men, and a general persecution began. An Act was passed in 1662 'for preventing mischiefs and dangers that may arise from certain persons called Quakers and others refusing to take lawful oaths.' Under this Act a Quaker thrice convicted of the offence might be sold into perpetual slavery at Tunis, Jamaica, Barbadoes, or Virginia; and the Act was rigidly enforced. Matters were only made worse by the Conventicle Act (q. v.) of 1670, under which William Penn (q. v.) was tried for preaching.

On the accession of James II. (1685) a petition was presented to the king and Parliament setting forth 'the suffering condition of the peaceable people called Quakers, only for tender conscience towards Almighty God.' During the previous reign above 5000 of their number had been imprisoned; about 1380, including 300 women, were still confined; of these, 300 were imprisoned only because they refused to take an oath. Since the Restoration above 320 had died in prison. In the gaol of Newgate they were crowded in such numbers that they died of suffocation and malignant fever. The tenderness of conscience for which they suffered implied, it is true, a refusal to pay tithes, and an obstinate perverseness in interrupting the public worship of other Christians; but the severity of the punishments inflicted, as described in this petition, was quite unjustifiable.

The persecution of the Friends came to an end when James II. set aside all penal laws against dissenters by his own 'dispensing power,' that is, by proclamation. The Toleration Act of 1689 permitted the Friends to hold their meetings in peace on condition of signing three documents, a declaration against transubstantiation, a promise of fidelity to the government, and a confession of Christian belief. Since that time there is little of importance to record in the history of the society In America during the present century there have been some outbursts of latitudinarianism in the body—e.g., the 'Hicksite' movement, which was begun in 1827 by Elias Hicks, and almost rent the sect in twain. The total number of members belonging to the society is about 120,000, of whom 90,000 are in the United States.

The following account of the doctrines, practice, and discipline of the S. of F. is taken from an authorised statement of their own published in 1800:—

1. *Doctrine and Practice.*—They agree with other professors of the Christian name in the belief in one eternal God, the creator and preserver of the universe, and in Jesus Christ, his Son, the Messiah and the Mediator of the new covenant. To Christ alone they give the title of the Word of God, and not to the Scriptures, although they highly esteem these sacred writings in subordination to the Spirit, from which they are given forth.

It is their belief that in order to enable mankind to put in practice the sacred precepts of Scripture, many of which are contradictory to the unregenerate will of man, every man coming into the world is endued with a measure of light, grace, or good spirit of Christ, by which, as it is attended to, he is enabled to distinguish good from evil, and to correct the disorderly passions and corrupt propensities of his nature. Being thus persuaded that man without the spirit of Christ inwardly revealed can do nothing to the glory of God or to effect his own salvation, they think this influence especially necessary to the performance of the highest act of which the human mind is capable, even the worship of the Father of lights and of spirits; therefore they consider as obstructions to pure worship all forms which divert the attention from the secret influence of this unction from the Holy One, and believe it to be their duty to wait in silence to have a true sight of their condition bestowed upon them. On the same principle it follows that the ministry they approve must have its origin from the same source. Hence arises their testimony against preaching for hire, in contradiction to Christ's positive command—'Freely ye have received, freely give;' and hence their conscientious refusal to support such ministry by tithes or other means.

As they cannot encourage any ministry but that which they believe to spring from the influence of the Holy Spirit, so they do not restrict this influence to the male sex alone, but allow such of the female sex as seem to be endued with a right qualification for the ministry to exercise their gifts.

The two sacraments in use among most Christians they regard as useless, holding, as regards baptism, that it belonged to an inferior dispensation, and as regards the Lord's Supper, that since communion between Christ and his Church is maintained only by a real participation of his divine nature through faith, it is unnecessary to attend to that which is merely the shadow of this reality

Few of their tenets are better known than their testimony against oaths and against war. With respect to the former of these, they abide literally by Christ's command (Matt. v. 34), 'Swear not at all.' From the same authority (Matt. v. 39, 44, &c.), the example of Christ himself, and the convictions of his spirit in their hearts, they are led to believe that wars and fightings are utterly repugnant to the gospel. They inculcate submission to the laws in all cases where conscience is not violated. But they hold that as Christ's kingdom is not of this world, it is not the business of the civil magistrate to interfere in matters of religion at all.

They have always disused the ordinary names of the months and days because these were given in honour of heathen deities, and the custom of speaking to a single person in the plural number, because it arose from motives of adulation. They condemn all compliments, superfluity of apparel and furniture, outward shows of rejoicing and mourning, the observance of days and times, public diversions, and all other vain amusements.

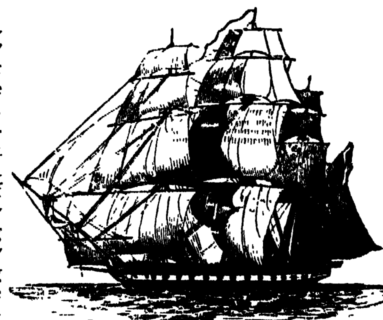
2. *Discipline.*—The chief purposes which their discipline has in view are the relief of the poor, the maintenance of good order, and the recovery of such as are overtaken in faults. The principle on which their discipline is practised is that laid down by Christ himself (Matt. xviii. 15-17). For purposes of discipline quarterly meetings were at first appointed to be held. Afterwards subordinate monthly meetings were appointed for subdivisions of the districts which met quarterly, and in 1669 a yearly meeting was established to superintend the whole.

A monthly meeting is composed of several congregations. Its business is to provide for the subsistence of the poor, and for the education of their children; to judge of the fitness of persons desiring to be admitted as members; to excite due attention to the discharge of religious and moral duty, and to deal with disorderly members; to grant certificates of membership to members changing their residence; to allow marriages; and to appoint overseers to see that the rules of the discipline be put in practice. Several monthly meetings compose a quarterly meeting, at which are produced written answers from the monthly meetings to certain queries respecting the conduct of the members, which are sent, all digested into one set of answers to queries, to the yearly meeting. The yearly meeting has the general superintendence of the Society in the country, and therefore gives its advice and makes such regulations as circumstances seem to require. It also finally determines appeals from the quarterly meetings. As women are permitted to have a share in the support of their discipline, they also have their monthly, quarterly, and yearly meetings of their own sex. The yearly meeting of 1675 appointed a meeting to be held for the purpose of helping in cases of suffering for conscience' sake, which, as a standing committee of the yearly meeting, has continued to the present day under the name of the Meeting for Sufferings. See Fox's *Journal*; Sewel's *History of the Christian People called Quakers* (Lond. 1722); Bevan's *Refutation of some Modern Misrepresentations of the S. of F.* (Lond. 1800); Gurney's *Observations on the Peculiarities of the S. of F.* (Lond. 1824); *A Summary of the History, &c., of the S. of F.*, issued by the Meeting for Sufferings (1800); Neale's *History of the Puritans* (Toulmin's ed.).

Fries, Elias Magn., a Swedish botanist, born 15th August 1794, in the district of Femsjö in Smaland, studied at the University of Lund, and in 1824 became a titular professor there. In 1834 he left Lund for Upsala to hold the chair of Practical Economics, to which the professorship of Botany was united in 1851, but in 1859 he retired on a pension. F. was elected a member of the Swedish Academy in 1847. Most of his earlier works treat of fungi and lichens, *e.g.*, *Observationes Mycologicæ* (1815-18), *Scleromycetes Sueciæ Exsiccati* (1818), *Lichenes Sueciæ Exsiccati;* and it was as a mycologist and lichenologist that F. first took a place in science. His *Systema Mycologicum* (3 vols. 1820-32), with the supplementary *Elenchus Fungorum* (1828), *Epicrisis Systematis Mycologici* (1836-38), *Monographia Hymenomycetum Sueciæ* (2 vols. 1857-63), &c., made an epoch in this branch of botany. In *Lichenographia Europæa Reformata* (1831), a work which the Academy of Science rewarded with the Linnæan gold medal, he appears to mediate between old and new views, and especially he has struggled to preserve the often misunderstood Linnæan nomenclature in describing Scandinavian plants. Of his works in this direction, the chief are *Novitiæ Floræ Suecicæ* (2d ed. 1828), *Novitiæ Floræ Suecicæ Continuatio* (vols. i.-iii. 1832-42), *Flora Hollandica* (1817-18), *Flora Scanica* (1835), *Summa Vegetabilium Scandinaviæ* (1846-49). In the last-named works he unfolds a natural system, in many respects different from those of Jussieu and Decandolle, based on morphology and biology, the leading features of which he had already sketched in the incomplete *Systema Orbis Vegetabilis* (1st part, on fungi, algæ, and lichens, 1825). F. has also published some works of a practical kind, *e.g.*, *Sveriges ätliga och giftiga Svampar* (1860 66), &c., with many popular tracts on the history, physiology, and geography of plants. These last are mostly collected in the form of *Botaniska Utflygter* (3 vols. 1843-64). F. died 8th Feb. 1878.

Fries, Jakob Friedrich, a German philosopher, was born at Barby, in Prussian Saxony, 23d August 1773, studied at Leipsic and Jena, became a professor at Heidelberg in 1805, and died 10th August 1843. His standpoint is in the main that of Kant, with a supplementary doctrine of philosophical anthropology—an attempt to analyse the nature of the soul and the conditions under which it apprehends truth. The aim of his 'system' was to effect a reconciliation between the critical philosophy and faith. His chief works are *System der Philosophie als evidente Wissenschaft* (Leips. 1804); *Neue oder anthropologische Kritik der Vernunft* (3 vols. Heidelb. 1807); and *Die Lehren der Liebe, des Glaubens, und der Hoffnung* (Heidelb. 1823). See Henke's *Leben des F.* (1867).

Fries'land, or **Vries'land.**—1. W. F., or simply F., with the islands Ter Schelling, Ameland, and Schier Monnikoog, constituted by the Treaty of Utrecht in 1579 one of the Seven United Provinces, is a province of Holland, bounded by the North Sea, the Zuyder Zee, and the provinces Overyssel, Drenthe, and Gröningen. Area, 1253 sq. miles; pop. (1874) 311,246. It is a flat country, partly protected by dikes, the N. and W. being marsh, while in the S. and E. are found great heaths, and stretches of peat bog. Internal communication is easy, from the large number of canals, streams, and lakes. The soil is rich, and well suited for pasturage and tillage, especially where it is recovered fen-land. The chief productions are wheat and rye, but flax, hemp, chicory, colza, and clover are also largely cultivated. Butter and cheese are exported to England in great quantity. The chief towns are Leeuwarden, Harlingen, Franeker, and Sneek. The inhabitants are well educated and prosperous, and are chiefly of the Calvinistic persuasion. All the dikes and canals are placed under a Board of Control, which levies a direct tax on landowners for their maintenance.



2. E. F., now known by the name Aurich, the smallest of the six high bailiwicks of Hanover, is bounded by the North Sea, Holland, Aremberg, and Oldenburg. Area, 1144 sq. miles; pop. (1871) 195,394. The natural features of the land and occupations of the people are the same as in W. F. Chief towns, Emden and Aurich.

Frieze (Fr. *frise*, Ital. *fregio*, 'a fringe of ornament'), in classical architecture, is the portion of an entablature between the cornice and architrave. The name was also applied to a broad band of relievo sculpture carried round the *cella* of a Greek temple, just under the ceiling of the portico. An ornamental F. is often added to the modern cornice.

Romanesque Frieze in Denkendorff.

Frig'ate (Fr. *frégate*, Ital. and Port. *fregata*, of doubtful origin, but probably meaning an 'undecked ship'), a name first given to a long, narrow, and swift vessel propelled by oars or sails, or both, used in the Mediterranean. During the last century and the first half of the present a F. was a ship of war built specially for speed, carrying not more than fifty guns, and belonging to a class below the larger, more powerful, but less handy, line-of-battle ship.

Frigate.

With the alterations in the navy which have followed on the use of iron in construction, of steam propulsion, of armour plates and heavy guns, the name F. has lost its special meaning to a great extent, and is applied to such vessels as the *Warrior*, *Northumberland*, &c., which combine the highest speed and the greatest fighting power.

Frigate Bird (*Attagen* or *Tachypetes aquila*), a genus of Natatorial or Swimming birds, famous for their powers of flight. They are included in the Pelican family (*Pelecanidæ*), and are distinguished by the bill being longer than the head, rounded above, concave below, and hooked at its tip. The wings are very long and narrow, the first and second quills being longest. The tail is also elongated and deeply forked. The tarsi are short and partly feathered.

Frigate Bird.

The throat is naked, and appears capable of being dilated at will to form a kind of pouch, analogous to that structure in the Pelicans (q. v.). The colour is black glossed with green, but the throat 'pouch' is scarlet. The total length of the bird is 3 feet, and the expanse of wings from 6 to 8 feet. The F. B. inhabits the tropics, and is hence named the 'tropic bird.' It may be seen hovering for lengthened periods in mid air without a movement of the wings being perceptible.

Frin'ges, in optics, are the coloured bands of light observed in Diffraction (q. v.) phenomena.

Fringe-Tree, a name given to a species of plants belonging to the *Oleaceæ* or olive order, and to the genus *Chionanthus*. The F.-T. or 'snow-flower,' as it is also named, is the *C. Virginica* of botanists, and grows in the United States of America, attaining a height of from 20 to 30 feet. The name is derived

from the form of the corolla, which has the appearance of being divided into four elongated portions.

Fringill'idæ, a large family of Insessorial birds belonging to the Conirostral section of the order, and represented by the finches, sparrows, linnets, &c. A large number of sub-families are included in this group, in which the bill is conical with a sharp tip, the upper mandible not being toothed. The claw of the hinder toe is usually longer than that of the other digits. The neck is short, and the tarsi are of moderate size.

Frisch'es Haff (*i.e.*, 'fresh-water bay'), a lagoon of the Baltic, on the coast of Prussia, between Elbing and Königsberg, which receives the Fregel, Friesching, Passarge, and Vistula, is 60 miles long, from 4 to 12 broad, and has an area of 318 sq. miles. It was separated from the Baltic by a long narrow spit of land called the Frische Nehrung till 1510, when the waters of the Haff burst through the barrier and formed a *gatt* or channel of communication with the outer sea. The *gatt* is not more than 15 feet deep, and all large vessels, therefore, unload at Pillau at its mouth, whence the cargoes are conveyed to the lagoon ports by lighters.

Fris'ians (in their own language *Frisan;* the Lat. *Frisii*, later *Frisiones*, *Frisones*), a Low German people often referred to by Tacitus. The Romans first met with them in the N.W. corner of Germany and conquered them. They took part in Civilis' insurrection in 70 A.D. Including the kindred Chauci (between the Ems and Elbe), they peopled the coast of the North Sea from the islands of the Rhine and Scheldt as far N. as Slesvig. The Zuyder Zee divided them into Frisii Majores on the W. and Frisii Minores on the E. After their subjugation about the beginning of the 8th c. by Pippin of Heristal and Karl the Hammer, the name Frisian was restricted to the eastern section, whose lands were now divided into W. Friesland or simply Friesland, between the Zuyder Zee and the Lauwer Zee, and E. Friesland; while those on the peninsula of Jutland and the adjacent islands were called N. or Shore F. Among the descendants of the Frisii Minores (on the W. of the Zuyder Zee), the Old Frisian language, intermingling with Frankish and Lower Saxon, produced the 'Dutch' language. Among these there arose, from the 10th and 11th centuries, numerous hereditary lords and counts; but in the 13th c. the territory came under Holland. All these F. were distinguished for their free communal institutions, set forth in their old laws, which are recognised in the oldest English laws, for the F. were an essential element of the English conquerors of Britain. In 802 Karl the Great formulated their laws anew in the *Lex Frisionum*. In the 15th c. the F. were forced to become subjects of the German empire, and in 1523 they were joined to Burgundy by Karl V. Their subsequent history belongs to Holland and Hanover.

In free spirit and skilful seamanship the F. are very like their northern neighbours the Scandinavians, and Rask pointed out that Frisian is, much more than any other Low German dialect, a transition to Scandinavian. The resemblance of Frisian to English is still more striking. On this point see Davies *On the Races of Lancashire*, in the *Trans. of the Philol. Soc.* (1855), and *Archaic and Provincial English compared with Dutch and Friesic*, ibid. (1858), by M. de Haan Hettema, who gives 1000 words that are the same in those three languages. Several English poems, even some of Shakespeare's plays, have been put into Frisian almost word for word. The F. regarding, with some reason, Hengest as a Frisian exile, claim kinship with the English, as in their proverb :—

'Good butter and good cheese
Is good English and good Freese.'

The likeness descends to inflexions, *e.g.*, the English sign of the infinitive *to* is found in Old Frisian, and in no other Germanic dialect.

The oldest form of the language is in the old law-books, the most interesting of which are *Emsiger Domen* (beginning of 14th c.), *Brokmerbrief* (after 1250), and *Asegabuch* (about 1200). Every district had its dialect. From the 15th c. onwards the Frisian language was pressed on all sides by Dutch, German, and Danish. New Frisian is the name given to country dialects spoken in the different Frisian districts. There are several minor poems written in this dialect by Hansen (the comedy *Di Gidtshals*, Sonderb. 1833) and Foocke Hoissen Müller (1857). Epkema published in 1820 the older poem *Friesche Rymlerye* of Gilbert Japicx, with a vocabulary. Noteworthy are the popular comedy *Waatze Gribbert's brilloft* (beginning of last century) and the popular book *It Libben fen Aagtje Ysbrandts*. Hettema, E. and J. G. Halbertsma, Salverda, and Veen are well-known philologists. *De Vrije Fries*, a Frisian periodical, has been published since 1850 by the Frisian Society, established at Franeker in 1829. Grimm has treated the language in his great German grammar. The best dictionaries are Richthofen's *Altfriesisches Wörterbuch* (1840) and Outzen's *Glossarium* (1837). Rask's highly useful *Frisisk Sproglaere* (Copenh. 1825) has been translated into Dutch by Hettema (Leeuw. 1832).

Frit, or **Fritt** (Fr. *fritte*, Lat. *frictus*, 'dried'), in glass-making, the calcined mixture of the constituents of glass before being melted.

Frit, a name given to the *Chlorops* or *Oscinis* F., a species of Dipterous insects or flies. The larvæ are exceedingly destructive to barley crops, especially in N. Europe. The adult fly is very small and of blackish colour.

Frith, William Powell, R.A., was born near Ripon in Yorkshire in 1819, entered the Royal Academy in 1838, and in 1839 exhibited his 'Malvolio before the Countess Olivia.' Since then he has produced an extraordinary number of bright and 'taking' works, always interesting in subject, graphic, gay in colour, and marked by a certain superficial finish. He has sought subjects chiefly in Shakespeare, Goldsmith, Molière, and Sterne; and among his principal pictures, most of which are well known from engravings, are his 'Duet Scene' from *Twelfth Night*, 'Falstaff and the Merry Wives of Windsor,' 'Sterne in the Grisette's Shop,' the 'Village Pastor' (which secured his election as Associate in 1845), and later his 'Coming of Age' (1849), one of his best works, and 'Life at the Seaside' (1854). F. was elected R.A. in 1853. His 'Derby Day' (1858) and 'Railway Station' (1862), his most popular works, were sold for immense sums—the latter, it is said, for about £10,000. In 1872 he was commissioned by the Queen to paint the 'Marriage of the Prince of Wales.'

Frit'illary, a name given to several distinct species of *Lepidoptera* or butterflies—the term being suggested by the resemblance presented by the wings of the insects to the coloration of the flower of the plant of the same name.

Fritillary (*Fritillaria*), a genus of Endogenous plants belonging to the natural order *Liliaceæ*, and represented by the 'crown imperial' (*F. imperialis*), so named from its depending flowers resembling the form of a crown. This beautiful plant is a native of Persia, and is grown in our gardens. Its bulb is said to be poisonous, and the leaves of its *perianth* or floral envelope (see FLOWER) have nectar glands or depressions at their bases. The common F. (*F. meleagris*) flowers in May or even earlier, and grows wild in the southern parts of England. Its flower is flesh-coloured.

Fritillaria imperialis.

Friu'li (Ger. *Friaul;* a corruption of the Lat. *Forum Julii*), a fertile stretch of coast-land in the N. of the Adriatic, which in the middle ages formed an independent duchy, but is now divided between the Italian province of Undine and the Austrian district of Görz-Gradiska. Area, 3905 sq. miles. The *Furlani* are mostly Italian, but speak a peculiar dialect.

Friv'olous and Vexa'tious, a legal term under the Act regulating the trial of election petitions. If a petition or opposition to a petition be reported to the House as F. and V. by its committee, the party in fault is liable in full costs.

Fröbel, Friedrich, a notable German educationist, was born at Oberweissbach, in Schwarzburg-Rudolstadt, 21st April 1782,

studied at Jena, and in 1803 became a teacher in Frankfurt. His model was Pestalozzi, in whose Institute at Yverdun he worked as a private tutor during 1808–10. Thence he went to Göttingen and Berlin to complete his imperfect culture, took part in the campaigns of 1813–14 as a volunteer, and in 1817 established at Keilhau, near Rudolstadt, a school which soon became famous for its excellent teaching. Here he first gave to the world an outline of his pedagogic system in his *Die Menschenerziehung* (Keilhau, 1826), which consists in viewing the mind not as a series of independent faculties, which should be separately cultivated, but as a living organism in which all the parts should co-operate to produce an harmonious unity. The application of his 'idea' to the education of children of tender years was an undoubted benefit; and as the founder of the now famous *kindergärten* (1836–42) he is certain to be remembered in the annals of pedagogy. After spending some time in Switzerland, where he established some schools on his own system, he returned to Germany, and devoted himself exclusively to the education of children. He died at Marienthal, 21st June 1852. F.'s *Mutter- und Koselieder* (1843) is fairly described in its fuller title as 'poetry and pictures for the noble nurture of child-life,' with border-drawings, explanatory text, and accompanying songs. Its faults are superficial; its merits deep and enduring. The title-page also bears a characteristic summons: *Kommt, lasst uns unsern Kindern leben* ('Come, let us live for our children'). See Hanschmann's *Friedrich Fröbel* (Eisenach, 1875).—**Julius F.**, a nephew of the former, was born at Griesheim in 1805, held the mineralogy chair at Zürich University 1833–44, edited a Radical paper, removed to Germany (1846), and became a member of the Parliament at Frankfurt in 1848. Along with Blum (q. v.) he conveyed the congratulations of the 'Left' to the insurgents of Vienna, and was arrested on the recovery of the city. Escaping to Switzerland, he fled thence to the United States, where he was in turn editor, lecturer, merchant. In 1857 he returned to Germany, became editor of a journal first at Vienna (1862), then at Munich (1866), and was appointed German consul at Smyrna in 1873. His chief works are *System der Socialen Politik* (2 vols. 1847); *Theorie der Politik* (1861–64); *Aus Amerika* (2 vols. 1857–58; Eng. trans. 1859); and *Die Wirthschaft des Menschengeschlechtes* (1870).

Fro'bisher, Sir Martin, the first famous English navigator who devoted himself to the search for a N.W. passage from the Atlantic to the Pacific and to India, was born at Doncaster about the middle of the 16th c. Respecting the discovery of the passage, he considered that it 'was the only thing of the world that was left yet undone whereby a notable mind might be made famous and fortunate.' After vainly appealing to the London merchants for support, he obtained the patronage of Dudley, Earl of Warwick, and was enabled to fit out a squadron of three vessels, whose united burthen was under 70 tons, and set sail 8th June 1576. As the expedition passed Greenwich, Queen Elizabeth bade the mariners farewell 'by shaking her hand at them out of the window.' Passing the S. coast of Greenland, he crossed to Labrador, and discovered the inlet which still bears his name. Five of his sailors going ashore against orders were carried off by the natives and never heard of more. After collecting a quantity of mica, which was said to contain a large quantity of gold, F. set sail for England and arrived in October. A second voyage was undertaken in 1577, and a third in 1578, but without noteworthy results. F. died at Plymouth, 7th November 1594, of a wound received at an attack on Brest.

Frobisher Bay or **Inlet** (formerly misnamed a strait), extending W.N.W. from the S. of Davis Strait, on the N. side of the peninsula of Meta Incognita, which intervenes between it and Hudson Strait. The middle of its entrance is in lat. about 63° N. It is about 100 miles long and 20 broad.

Frog, the name given to various genera of Vertebrate animals included in the class *Amphibia* (q. v.), and in the order *Anoura* or *Batrachia*. Frogs are not *reptiles* in a zoological sense, since, like all Amphibians, they possess *gills* or branchiæ in early life, though afterwards they breathe solely by lungs. The order *Anoura* ('tailless'), to which the F. belongs, is characterised by the adult being destitute both of gills and tail, the larva possessing both. Two pairs of limbs are present, the hinder limbs exceeding the fore-limbs in length. In the F. the five hinder toes are webbed, the four toes of each anterior limb being free. The skin is soft and scaleless. The dorsal vertebræ are hollow in front and convex behind. There are no ribs, but the transverse processes of the dorsal vertebræ are very long. The F. breathes by *swallowing* air rather than by *inhaling* it. The radius and ulna of the fore-limb, and the tibia and fibula of the hind-limb are ossified together. The upper jaw carries small teeth; the lower jaw is edentulous. There are only ten vertebræ in the spine. The tongue is fleshy, and is attached in front to the jaw, but is free behind. Consequently, it is the hinder extremity of the tongue which is protruded. The tympanum of the ear is not covered externally. Like all other *Amphibia*, frogs undergo a series of changes in passing from the young to the mature form. These changes collectively constitute the *metamorphosis*. The *tadpole*, or larval F., is fish-like, and is provided soon after its birth with horny jaws, and with external gills springing from the sides of the neck. These give place to internal gills, connected with cartilaginous arches borne on the hyoid bone; the young F. thus breathing after the fashion of a fish. The hind-limbs first appear, and have the form of small protrusions, whilst the fore-limbs are found within the branchial or gill chamber of the embryo. The larval tail is retained up to this date, but now begins to decrease in size. Lungs are meanwhile being developed, and as the latter organs appear, the gills disappear; the F. ultimately leaving the water, and during its adult life breathing atmospheric air, like other terrestrial animals. The oft-repeated stories of frogs being found enclosed in rocks reputed to have been of *solid* nature, are not to be credited. It is certainly true that these animals, on account of their cold-blooded nature and slow circulation, can maintain life on a limited supply of air, since the skin largely assists in the respiratory process. But the notions that they have been enclosed in solid rocks (often belonging to a geological period antecedent to that in which the earliest fossil traces of the F. are found), and that they could have lived thus for ages, only require mention to ensure their rejection as mere childish credulities. Dr. Buckland many years ago performed a series of experiments on frogs by enclosing them in cells cut in blocks of stone, with the view of testing whether or not any truth existed in such popular beliefs. He found that the duration of the existence of frogs and toads when enclosed in air-tight cavities was limited to a year or a little more. The common or grass F. (*Rana temporaria*) is too well known to need any description. The hind-limbs of the edible F. (*R. esculenta*) are, when properly cooked, esteemed delicate morsels by various nations on the continent of Europe, particularly the French. The latter species is somewhat larger than the grass F. The Bullfrog (q. v.) is another species common in America, and a second American species of the same name is the *R. clamitans* of naturalists. An African bullfrog is named *Tomopterna adspersa*, and to the genus *Rana* belong the pickerel F. (*R. palustris*) of N. America, and the shad F. (*R. halecina*) is also an American genus. The banded F. (*R. fasciata*) of S. Africa is a prettily-marked creature. Some more uncommon species of F. are the horned frogs (*Ceratophrys cornuta*) of S. America, which has horn-like points on the upper eyelids; and the nurse F. (*Alytes obstetricans*) of Europe, the males of which species have the curious habit of carrying the impregnated eggs in masses twisted round their legs, and of so supporting them during their development. The tree frogs or *Hylada* form a separate family.

Frog-Fish (*Batrachus*), a peculiar genus of Teleostean fishes belonging to the family *Batrachidæ*. The *B. grunniens* is a familiar example. It occurs in the Ganges and E. Indian seas, and is so named from the resemblance of the head to that of a toad or frog. The *Lophius piscatorius*, a great broad-headed fish frequently cast up on our shores, is also named F.-F., or more frequently 'fishing-frog.' See ANGLER-FISH.

Froissart, Jean, perhaps the most famous chronicler of the middle ages, was the son of a cabinet-painter, and was born at Valenciennes in 1337. At the age of twenty he undertook, at the request of Robert of Namur, to write the history of the wars of his time in France, England, Scotland, Spain, Brittany, Gascony, Flanders, &c., particularly those occurring after the battle of Poitiers. The first part of the Chronicle, which he laid at the feet of Queen Philippa at London in 1360, was founded on the Chronicle of Le Bel, the Canon of Liége. By Philippa's aid he travelled into Scotland, followed the Black Prince to Bordeaux, passed through Germany, and was present at the Visconti fêtes at Milan. In the employment as secretary

of the Duke of Brabant, and then of the Comte de Blois, he continued to move about for the purpose of noting down what wars were being carried on, and to verify the narratives of past wars. In particular he visited the chivalrous court of Foix. Most of the Chronicle was written in 1390–94, after which F. visited England, and gave an illuminated and illustrated copy of the 'book in scarlet velvet, with ten large silver studs set in gold, and golden clasps with rosework, also in gold,' to Richard II. He died at Chiamy about 1410. F. is imbued with all the vices of the chivalric system. No word of sympathy for any class but the nobility escapes him. Courage, courtesy, and the patronage of letters are his three virtues; they are compatible with many unpleasant types of character. His moral tone is lower than that of Joinville and Villehardouin, the chroniclers of the crusades. It has not even the serious purpose of history, like the Chronicle of the Monk of St. Denis. It is written to amuse, and its quaint garrulity and vivid descriptions, its constantly repeated moral and religious commonplaces, are probably as amusing to this age as to the 14th c. The best editions of F. are those by Buchon (3 vols. 1835–36) in the *Panthéon Littéraire*, by Siméon-Luce for the *Société de l'Histoire de France* (4th vol. 1875), and by Baron Kervyn de Lettenhove (16th vol. Bruss. 1876). There are two English translations, one by Lord Berners (Lond. 1525), and another by Johnes (1803–5). The language used by F. is of varying inflection. He often uses the rustic Romance idiom of a final *s* in substantives, and also the dialect called *ouchi Français*, from the frequent occurrence of *ch*. F.'s *Poésies* have been collected and published by Buchon in his edition of the Chronicle.

Frome, or **Frome Selwood**, a picturesque old town in the E. of Somersetshire, on a small river of the same name, a branch of the Avon, 12 miles S.S.E. of Bath by railway. It is near the remaining portion of the famous forest of Selwood, and has a handsome principal church and a grammar-school founded under Edward VI. The river is here crossed by a bridge of five arches. F. is noted for its ale, and has manufactures of broadcloths, kerseymeres, &c. It returns one member to Parliament. Pop. (1871) 9753.

Frond (Lat. *frons, frondis*, 'foliage'), the name given to the so-called *leaves* of ferns and other cryptogamous plants. Fronds differ from the leaves in that they bear the *fructification* or fruit of Ferns (q. v.). The name *thallus* is frequently employed in a technical sense as synonymous with F.

Fronde (from Lat. *funda*, 'a sling'), a name which arose during the sittings of a committee appointed by the French Parliament in 1647 to consider the arbitrary rights of taxation claimed by Mazarin for the king. The Duc d'Orleans acted as a sort of mediator, and as the members of the committee spoke more boldly in his absence, one of them, Buchaumont, compared his colleagues to the schoolboys slinging under the city walls, who stopped as soon as they saw the police. Mdlle. Montpensier, however, says that the word was used in the debates for 'having a shy' at the Cardinal without naming him. The party was called *La Fronde*, and each member a *Frondeur*. This reforming committee had many public rights under discussion; but the subjects on which perhaps they felt most bitterly were the taxes on articles brought into Paris. The arrest, by the Queen, of Broussel was the signal for an insurrection in Paris, of which Gondi, the Coadjutor, and Madame Martineau were the leaders. Anne temporarily granted the constitutional demands, but immediately after withdrew them. At this there was an open rupture, and Conti, Longueville, and Beaufort, the King of the Markets, put themselves at the head of the popular party in Paris. After a few small victories had been gained by the troops of Condé, and many provincial parliaments had declared for the king, a temporary peace was arranged. Then Condé and D'Orleans joined the F., while Molé, Gondi, and ultimately Turenne, went over to the court. Turenne, not yet converted, marched into Picardy, demanding the liberation of Condé and the other princes whom Mazarin had thrown into prison. After a siege of Bordeaux, this stage of the contest was closed by the treaty of Bourg. Mazarin's position was strengthened by the defeat of Turenne in Champagne by the Marshal Duplessis Praslin; but immediately after he was compelled to free the princes, and the Parliament resolved to banish him and all his relatives. Mazarin retired to the Elector of Köln at Bruhl, Condé was made Governor of Guienne, and the young king fell into the power of Gaston of Orleans. The successful leaders soon quarrelled, and after a vast deal of plotting, the Coadjutor Gondi was selected by the queen-regent as minister in room of Mazarin, and was made Cardinal de Retz. Public favour now turned against Condé, who left Paris, and strove to rekindle civil war. In 1651 he assembled at Bordeaux a force of 5000. Against the rebels were Turenne and Harcourt, the ablest soldiers in France after Condé. A few defeats at Cognac and Rochelle were counterbalanced by the return of Mazarin, which caused a revulsion of feeling, the Parliament passing a sentence of outlawry. In 1652 the prince's friend De Rohan was defeated in Anjou by D'Hocquincourt, who then with Turenne invested Orleans, which was saved for the F. by the singular energy of Mdlle. de Montpensier. Condé now came to Orleans, and defeated the royal army at Blesneau. Then followed the march of the hostile armies to Paris, and the terrible fight of St. Antoine, where Condé and Turenne displayed equal skill and courage, and the brutal attack on the Town Council of Paris. Some months of anarchy followed, the Frondeurs being divided into factions. At last the Parliament withdrew to Pontoise, dismissed Mazarin, and proclaimed Condé guilty of high treason. The latter fled to the Champagne frontier, and the war was continued for some time in Guienne by Conti, Marsin, and Genet. See Sainte-Aulaire's *Histoire de la F.* (3 vols. Par. 1827), and *Mémoires* of De Retz, Montpensier, and Rochefoucault.

Fronti'nus, Sex'tus Jul'ius, a Roman writer of the 1st c. He was *prætor urbanus* in 70 A.D.; was in 75 A.D. made governor of Britain, where he conquered the Silures and extended the Roman power. He was afterwards appointed *curator aquarum* and augur, and from an epigram in Martial seems to have been twice consul. He died about 104 A.D. F.'s works comprise *Strategematicon* (ed. princ. Rome, 1487), which treats of military matters; *De Aquæductibus Romæ*; fragments on measuring land, &c. They throw considerable light on Roman architecture and land tenure. The best edition of the *Strategematicon* is by Oudendorp (Leyden, 1779); of the *De Aquæductibus*, by Dederich (Wesel, 1841).

Fron'tispiece (Fr. *frontispiece*; Lat. *frons*, 'front;' *specere*, 'to see,' 'look at') is sometimes, but seldom, used to denote the principal façade of a building. Commonly the name is applied to the title-page of a book when it is surrounded with ornamental work or enriched with a vignette, or to the engraving placed opposite the title-page, and the subject of which illustrates the subject or text of the work.

Front'let is the name in the Old Testament (Exod. xiii. 16; Deut. vi. 8, xi. 18) for the article worn by the Jews which in the New Testament is called Phylactery (q. v.).

Fron'to, Mar'cus Corne'lius, a famous rhetorician of the 2d c., born at Cirta, in Numidia, settled at Rome, and gained the favour of Hadrian and Antoninus Pius. He was made tutor to M. Aurelius and to Commodus, who both entertained a warm affection for him, was offered but declined the dignity of proconsul, amassed great riches, and died about 170. F.'s contemporaries declared him to be, as an orator, second to Cicero alone, and a body of rhetoricians arose who chose him as their model, and were styled *Frontoniani*. Except a treatise, *De Differentiis Vocabulorum*, no work of F.'s was known to be extant until 1819, when Mai discovered at Milan a number of letters by F., which he published in 1815. Mai afterwards unearthed, in the Vatican, additional correspondence between F. and M. Aurelius and Commodus. These letters mostly relate to trifles, and are very tamely written. F.'s works were published by Mai (Rome, 1823), and by Naber (Leips. 1867).

Frosch'dorf, or **Frohs'dorf**, a village and stately castle in Lower Austria, 30 miles S. of Vienna, on the Leitha, and at the foot of the great Kaiserwald. The castle belonged to the Crottendorf family in the 13th c., and after passing through many hands, became the residence of the Duchesse d'Angoulême in 1844. It was the refuge and rendezvous of the elder Bourbons. The Comte de Chambord, its present occupant, has greatly improved the castle.

Frosino'ne, an old town of S. Italy, province of Latium, built on heights overlooking the confluence of the Cossa and

Sacco, 48 miles S S.E. of Rome by railway. It is identical with the Volscian *Frusino*, and has inconsiderable remains of an amphitheatre, walls, &c. The dresses of the inhabitants are very picturesque. Pop. 9234.

Frostbite is caused by cold of great severity, or applied for a long time to the surface of the body. It chiefly attacks those parts most distant from the centres of innervation and circulation, viz., the feet, hands, ears, nose, chin, cheeks, and the surface of the body generally. F. is characterised by insensibility or numbness, diminished or arrested circulation, and loss of motion or stiffness, and it may vary in severity from Chilblains (q. v.) to freezing and death of the part. In the one case there is suspension of vitality, and in the other complete death. When the stage of reaction occurs, the part not absolutely destroyed becomes red, swollen, and hot, and afterwards blue and livid, indicating a state of inflammation. This redness terminates in an abrupt line, called the *line of demarcation*, and the dead part remains contracted, and shrivelled, and finally becomes gangrenous, separating in a slough, or dropping off, if it be a part of a limb. Treatment:—Endeavour to bring about a return of sensibility and circulation *slowly* by placing the patient in a cold room, and applying friction with the hand. Snow or cold water may be rubbed on the part first, then friction by the hand alone, or with a little starch powder to prevent attrition. Afterwards some mild stimulating liniment may be used, and finally the part may be covered with cotton wool or flannel.

Froth-Fly, Frog-Fly, or **Froth-Hopper,** names applied to various species of Hemipterous insects, belonging to the family *Cercopidæ*, a group nearly allied to that of the *Cicadæ* or Cicadas. The common F.-F. or 'cuckoo spit,' as it is also named, is the *Aphrophora spumaria* of the entomologist. It produces while in the larval state a large quantity of a frothy exudation, formed from the juices of the plants to which these insects attach themselves. The larvæ and pupæ closely resemble the perfect insect, which, however, has wings. A Madagascar species (*A. Gondotii*) secretes a clear watery-like fluid without the frothy exudation. A second species common in England is the spotted hopper (*Cercopsis dorsivittata*).

Froude, James Anthony, an English historian, son of Archdeacon F., was born at Dartington, Devonshire, April 23, 1818, was educated at Westminster and at Oriel College, Oxford, and was made Fellow of Exeter College in 1842. He was at first a follower of the Rev. J. Newman. His *Shadows of the Clouds* (1847) and *Nemesis of Faith* (1849) were censured by the university authorities, who deprived F. of his fellowship. He wrote for *Fraser's Magazine* and the *Westminster Review* from 1850 to 1856, when he issued the first and second volumes of his *History of England from the Fall of Wolsey to the Defeat of the Spanish Armada*, the twelfth and last volume of which appeared in 1870. In 1867 his *Short Studies on Great Subjects* were published, and in 1869 he was elected Rector of St. Andrews University. F. was at one time editor of *Fraser's Magazine*, but gave up the position in 1871. In 1872 he lectured in the United States on the relations between England and Ireland, and his strictures on the Irish drew him into a lively controversy with Father Burke. In 1874 he was sent to the Cape of Good Hope by the Secretary of State for the Colonies to inquire into the Caffre insurrection. He returned to England in 1875. His latest work, *The English in Ireland in the Eighteenth Century* (3 vols. 1872–74), has been very severely criticised. F.'s history is, in a large degree, an elaborate defence of Henry VIII., and although the author is generally regarded as having failed in his special pleading, the work is of high value for the ample and fresh research which it displays, and for its glowing, polished, and animated English. F. has scarcely been surpassed as a master of language, but his authority has been greatly lessened by the animus which he has carried into history.

Fro'zen Strait, a passage leading N.W. along the N. coast of Southampton Island to Repulse Bay, is in lat. about 66° N., and is usually heavily encumbered with ice. It was navigated by Parry in 1821, but was found impenetrable in 1836-37 by Captain Back.

Fruc'ted, in heraldry, means fruited or bearing fruit, and the term is applied to a tree. The fruit is (heraldically) of a different colour from the tree.

Fruc'tidor ('fruit-month'), the name in the French republican calendar of 1792–1806 for the last month of the year, from August 18 to September 14. On September 4, 1797, Carnot's party in the Directory was overthrown, and sixty-five deputies were condemned to deportation on the charge of having conspired to restore monarchy.

Fruc'tose, or **Fruit-Sugar,** occurs, as its name implies, in ripe fruits. It is also present in molasses, the uncrystallisable syrup remaining after cane-sugar has been separated from the juice of the sugar-cane by concentration and crystallisation. F.-S. is uncrystallisable, and has the composition expressed by the formula $C_6H_{12}O_6$; but if it be boiled for some time with dilute sulphuric acid, it takes up a molecule of water, and becomes Glucose (q. v.), $C_6H_{12}O_6,H_2O$, a substance which may readily be obtained in the crystalline condition. The crystallisation of honey after it has been kept some time, and the formation of nodules of sugar in dried fruits—the raisin for example—are due to the same cause. The sugar of fruits is formed in all probability by the hydration of cellulose, brought about by the action of the acid of the unripe fruit. See CELLULOSE.

Frugo'ni, Carlo Innocenzo, an Italian poet, was born at Genoa, November 21, 1692. In his youth his family placed him against his will in a convent, from which he was freed by the influence of Cardinal Bentivoglio. He then filled the chairs of *belles lettres* at the universities of Brescia, Bologna, Modena, Genoa, and Rome, and was made poet-laureate, first to Antonio Farnese, Duke of Parma and afterwards (1749) to Philip of Spain, who had acquired Parma. F. died at Parma, December 20, 1768. He is an elegant prose writer, and his lyrics are pure in diction and smoothly versified. His *canzoni* are especially beautiful. His works were published at Parma in 1779; a more complete edition (15 vols.) at Lucca in the same year.

Fruit (Fr. *fruit*, from Lat. *fructus*), the name applied in botany to indicate the ripe *pistil;* but as popularly used, it denotes a great variety of structures. Botanically it should be confined to the result of the fertilisation and ripening of *one* pistil; but even in a scientific sense, it is given to collections of mature pistils which are aggregated together (as in the mulberry and pine cone) to form an apparently single fructification. The F. botanically may also include parts of the flower which, to a greater or less extent, have remained in contact with the pistil. Thus in the *acorn*, the fruit of the oak, the scale-like *bracts* or flower-leaves unite to form the 'cup' of the acorn; or in the strawberry, the bulk of the F. popularly so named is formed by the swollen fleshy *receptacle* (see FLOWER) covered with little yellow and ripe carpels or parts of the pistil. The study and determination of the F. involves several important considerations. (1) The due examination of the pistil itself is necessary for the determination of the nature and mode of formation of the F. (2) The result of certain parts or organs of the flower or pistil being *suppressed* in the F. has also to be allowed for. (3) The addition or formation of new parts or accessory organs which come in due time to form part of the F. Fruits have been very variously classified by botanists, but a proper classification founded on structural and physiological considerations is still a desideratum. A simple but hardly philosophical classification divides them into (1) *dehiscent* fruits, or those that open to allow of their contained seeds being scattered, and (2) *indehiscent*, or those fruits which simply rot on the ground, and allow the seeds to come in contact with the soil through their decay. Of dehiscent fruits, good examples are seen in the *pod* or *legume* of the pea, and in the *siliqua* or pod of the wallflower. Indehiscent fruits are exemplified by two sets—(1) those which are *dry*, such as *nuts* (acorn, &c.), and *achenes* (seen in buttercup, strawberry, &c.); and (2) those which are *fleshy* or *succulent*. The latter group of indehiscent fruits is exemplified by the apple, gooseberry, peach, &c. Such a mode of arranging fruits gives little or no information regarding their exact nature, and their relations to the flowers or plants of which they form part. A better classification may be founded on the homology of the pistil, and on its relations to the flower. Thus we may divide fruits (1) into *aggregate* or *multiple* fruits (such as are formed by *many* flowers), and (2) into *simple* fruits, formed by the pistil of *one* flower. Of the aggregate fruits the mulberry is a good example. It is formed of a 'head' of fruits, each derived from a single flower, and con-

sisting of a little one-seeded indehiscent nut enclosed in four fleshy pieces representing the perianth or modified flower envelopes. The *fig* represents another example of this group, since the fig F. is formed by a hollowed *peduncle* or flower-stalk, contained within which are numerous fruits, each consisting of a little single-seeded *achene*, with withered floral envelopes. A *pine cone* is a third example of a truly multiple fruit, since each woody scale or modified bract has two seeds at its base. *Simple* fruits which are each formed by the pistil of *one* flower, may be divided into (1) *indehiscent*, fruits formed of *one carpel*, as in the plum, cherry, &c. The plum (or cherry) is a *drupe* or 'stone' F., its *pericarp* or seed-vessel possessing a fleshy outer and a stony inner coat, the 'stone' containing a single non-albuminous seed. In wheat we have an achene or single-seeded F. with a thin pericarp and an albuminous seed. In nettle we also find an achene, but with a non-albuminous seed. The fruits of thistle and dandelion may be classed in the present group, since each little floret gives rise to an achene, the persistent *calyx* being developed to form the superior woolly down or pappus by means of which the F. is wafted about by means of the winds. The second division of simple fruits is (2) that in which the F. is *dehiscent* and consists of *one* carpel. The pea or bean exemplifies this group, as also does the F. of the willow. A third division is formed by (3) *indehiscent* fruits of several *free* carpels. In the buttercup numerous free carpels form the pistil and F., each carpel becoming an achene, and containing a single albuminous seed. In the bramble and raspberry (liable to be confused with mulberry) we likewise find the product of a single flower consisting of many carpels, represented by fleshy drupes, placed on a dry elevated floral receptacle. In the strawberry, again, we have many separate carpels imbedded in a fleshy mass formed by the succulent receptacle. Here, as in the bramble and raspberry, the solitary seed of each achene is without albumen. In the rose we find few or many carpels (achenes) contained within the hollowed extremity of the peduncle or flower-stalk. The fourth division of simple fruits is constituted by (4) those *indehiscent* fruits which are each formed of several *united* carpels. In the ash, for example, the fruit is a dry-winged achene or 'key,' formed of two united carpels; in the maple it is almost identical in every respect; in mallow it is formed by a whorl or circle of single-seeded carpels (achenes) united by their faces. Dead-nettle has a F. formed of four dry achenes; holly has a drupe formed of four carpels; in olive the F. is also a drupe formed of two carpels; in the potato we find a berry consisting of two fleshy carpels; in the apple, pear, quince, &c., a fruit (termed a *pome*) formed of five carpels enveloped in the succulent top of the peduncle; in the gooseberry and currant the F. exists as a berry composed of two carpels; in the carrot we find a similar number of carpels; and in the acorn three carpels exist, although only one of these is destined to ripen. A fifth division of simple fruits is that (5) in which *dehiscent* fruits, each composed of *several* united carpels, are included. Examples of this group are seen in the horse-chestnut, where a F. formed of three combined carpels is developed; and in the cowslip and primrose, where five carpels unite to form a pod. In the violet also three carpels combine to form a pod, and in wallflower two carpels unite to form the *siliqua* or pod, which opens or dehisces from below upwards. In the poppy many carpels form the F., the seeds escaping by pores under the stigma. The sixth group of simple fruits is that (6) in which *dehiscent* fruits are contained, each F. consisting of several *free* carpels. Of this group are the fruits of aconite, larkspur, &c., where three or more dry pods exist, and split in a longitudinal manner. Fruits present many interesting points in connection with their physiology. The dispersion of the seeds is secured by such contrivances as winged appendages (maple, ash), pappus (dandelion), hooked processes for attachment to the fur of animals, and means for forcible dehiscence (as in balsam, where the seeds are scattered by the valves of the F. acting after the fashion of miniature pop-guns). Of the facts connected with the physiology of F. the most important are, firstly, recognition of the fact that F. is not perfect, botanically speaking, unless it contains duly-fertilised seeds. Some *cultivated* fruits, however, such as certain varieties of oranges and grapes, contain no perfect seeds; and the banana and plantain fruits are most palatable when seedless. Old trees (*e.g.*, orange) often produce seedless F. Fruiting appears, and necessarily, to impoverish a plant. Annuals die after fructification. Fruits are often greatly improved by pruning operations, and by checking the growth of the roots, so that the energies of growth are detracted from the formation of wood to that of F. Cultivated fruits are greatly improved by allowing only a moderate quantity to ripen. The chemistry of fruits is a complicated subject, the composition of a F. varying greatly at various stages of its progress. Briefly stated, the changes which occur in the process of ripening consist chiefly in a diminution of the quantity of *water* and *woody matter*, and an increase in the quantity of *sugar*. The time which elapses between the expansion of the flower and the ripening of the F. varies considerably in different plants. Thus some oaks require eighteen months to produce F. after flowering; and cedars require twenty-seven months; strawberries ripen in two months; apples, walnuts, plums, &c., in from three to five; and lower plants (such as mosses) require usually a long period of twelve months or more. An increase of temperature accelerates *fruiting*; and different fruits ripen best in different climates. Apples and pears thrive best in temperate climates, while mangoes and breadfruit require a tropical heat. See FRUIT TRADE.

Law regarding Fruits.—Fruits, as part of the soil, belong to the proprietor of it; but when they are the produce of industry and yearly seed, they are in England and in Scotland held to be personal estate. Fruits gathered are the property of the *bona fide* possessor.

Fruit, Malicious Injury to. See GARDENS OR ORCHARDS, STEALING FROM.

Fruit-Crow, the name applied to several species of Conirostral *Insessores* belonging to the sub-family *Gymnoderinæ*. Of this group the *Gymnoderus fœtidus*, or bare-necked F.-C. of Brazil and Guiana, is a typical example. It attains a size averaging that of a common Jackdaw (q. v.), and derives its name from the naked state of the upper part of the head, neck, and throat. The bald F.-C. (*Gymnocephalus calvus*) is another example, and belongs to a different genus. It is common in Cayenne, Guiana, and other parts of S. America: the entire front of the body is destitute of feathers. This species is also named the 'capuchin baldhead.' The fruit-crows eat snails, worms, &c., in addition to their vegetable diet.

Fruit-Garden. The cultivation of fruits has been practised by man from the earliest times. Especially in the records of Eastern nations are evidences of the successful practice of fruit-culture even in very early times to be met with. Some facts relating to the cultivation of fruit have been detailed in a preceding article. The general law that the process of fruiting is one which detracts from the nutrition of the plant as a whole lies at the root and basis of the fruit-grower's operations. Thus, while due attention may be paid to the nourishment and growth of the plant prior to flowering, excessive attention to the general growth or flowering tends to lessen the fruit-producing qualities of the plant. Anything which deflects the nutritive powers from the fruit of necessity injures the latter; and hence we find that by checking the growth of the root, by 'ringing the bark' (that is, cutting out a ring of bark so as to accumulate sap above the wound and near the fruit), and by pruning, fruit-growers contrive to nourish the fruit at the expense of other parts and organs of the plant. The careful selection of a site for a F.-G. bears a most important relation to the successful growing of fruit; so does the construction of Hothouses (q. v.), &c. An acquaintance with the various methods of growing fruit-trees, and of providing for their nourishment, as also of the diseases to which they are liable, is necessary to the fruit-gardener. He must also be acquainted with such operations as Grafting (q. v), Pruning (q. v.), and Transplanting (q. v.).

Fruit-Pigeon, the name given to a species of Pigeons (q. v.) belonging to the genus *Carpophaga*, in which a knob exists during the breeding season at the base of the upper mandible. The wings have the second to the fourth quills longest. The tail is long, and the outer toe longer than the inner. The Oceanic F.-P. (*C. Oceanica*) of the Pelew Islands is the best-known example. It attains a length of 14 inches, and is grey above glossed with green; the same colour, but of a lighter tint, also prevailing in the under parts. Fruit-pigeons aid in disseminating the nutmeg tree: they feed on the outer husk, swallowing the hard seed, which is voided along with the fæces, and is thus placed amid conditions favourable to its growth.

Fruit Trade, an industry of great and growing importance, extent, and variety. Two causes have of recent years conspired to give an enormous impetus to the trade—(1) the increased facility and rapidity of intercourse by steam communication, thus enabling fresh and tender fruits to be sent to distant markets; and (2) the development of the art of preserving fruits in many ways, such as by 'tinning,' by treatment with sugar, the manufacture of jams, jellies, &c. In the Board of Trade returns fruits are classified under various heads—as raw fruits, which apparently includes all fresh and succulent fruits excepting those of the orange tribe. Of these there were imported in 1874 2,622,914 bushels. Of oranges and lemons there were imported 2,405,054 bushels; fruits preserved in sugar and otherwise, 4,189,717 bushels; currants, 972,455 cwt.; and raisins, 505,361 cwt.; besides plums, prunes, and miscellaneous dried fruits. Among fruits are also reckoned almonds, of which there were imported 77,284 bushels; and nuts, which includes walnuts, hazel-nuts, and chestnuts, to the value of £550,463. These figures, of course, give only the faintest idea of the F. T., which in its proper signification includes the great vine culture, as well as the growth of apples for cider, cherries for Kirschwasser, and other fruits used for liqueurs.

Frumen'tius, St., the apostle of Ethiopia, was born at Tyre about the beginning of the 4th c. In his early life he sailed to Ethiopia, where all the ship's company were captured and slain, save himself and another youth named Edesius. These two were carried as slaves to the Ethiopian court, where F., soon winning the royal favour, was made secretary to the king, and, on the king's death, tutor to the young prince. The Queen placing wide authority in F.'s hands, he took advantage of his power to introduce Christianity, and founded the first Christian church built in Ethiopia. Aided by Edesius, who had likewise obtained considerable influence, he organised missions which made numerous converts, and on removing to Alexandria in 326, asked Athanasius, bishop of that city, to appoint a special bishop for Ethiopia. Athanasius made F. himself Bishop of Auxuma, whereupon he returned to Ethiopia and proselytised with great success. He died about 360. See Ludolf's *Historia Æthiopica* (Frankf. 1687).

Frus'tum, in solid geometry, is a portion of a solid, usually a pyramid or cone, bounded by two *plane* sections.

Fry, Elizabeth, an English philanthropist, was born at Bramerton, near Norwich, 21st May 1780. She was the daughter of John Gurney, a rich merchant and banker, and a member of the Society of Friends. After a gay visit to London, where she had met Peter Pindar (Dr. Wolcot), Mrs. Inchbald, and Amelia Opie, Elizabeth was greatly affected by the preaching of an American Quaker, William Savery. In 1800 she married a strict Quaker in Joseph Fry, and henceforth devoted herself to a life of pious charity. She visited Newgate (1813), and found some 300 women suffering, under the old prison system, the greatest privations and misery. Having supplied them with clothes, and otherwise relieved their condition, she further received permission to establish a school and factory in the prison (1817), and also organised a ladies' association for reforming prisoners. She subsequently carried improvements into most of the gaols, asylums, and hospitals of Britain, and made several journeys with a similar object into France and Central Europe. She died at Ramsgate, 12th October 1845. See *Memoirs of E. F.* (2 vols. Lond. 1847), by her daughters.

Fryxell', Anders, a Swedish historian, born 7th February 1795, at Hesselskog, in Dalsland, studied at Upsala, where he graduated in 1821, and in 1828 was made Rector of the Grammar-school of St. Mary in Stockholm. In 1834 he undertook a tour for historical inquiry in Denmark, Prussia, Poland, Austria, Belgium, and Holland, returning in 1835, when he was appointed parish minister of Sunne, in Vermland. He became a member of the Swedish Academy in 1840, doctor of theology in 1845, and a member of the Swedish Academy of Science in 1847. F.'s *Berättelser ur Svenska Historien* ('Narratives from Swedish History,' 40 vols. 1823–71) has made its author the most popular of all historians in Sweden. Other important works are *Handlingar rör. Sveriges Historia* (4 vols. 1836–43); *Om Aristokratfördömandet i Svenska Historien* (4 parts, 1845–50), a polemical work, directed against Geijer; and *Bidrag til Sveriges Literaturhistoria* (9 parts, 1860–62). Translations of the first volumes of the *Handlingar* have been published in English by Schoultz (2 vols. Lond. 1844), and in German by Homberg (2 vols. Stockh. 1843). The part relating to Gustav Adolf was translated into German by Homberg (2 vols. Leips. 1842–43), into French by Mademoiselle N. du Puget (Par. 1839), and into Dutch by Radijs (Utrecht, 1844), and the part treating of Gustav Vasa into German by Ekendahl (1831).

Fuad-Mehmed Pasha, a Turkish statesman and man of letters, was born in Constantinople about 1814. His father was a poet of eminence, but his property was confiscated by Sultan Mahmud, and F. had to study medicine. In 1834 he was appointed physician to the Admiralty, and as such accompanied an expedition to Tripoli. After this, however, he became a diplomatist, filling in succession the posts of attaché (1840) of the Turkish embassy in London, second dragoman of the Porte (1843), special commissioner during different years to Spain, Portugal, and Russia, first dragoman, grand referendary of the Divan, and commissioner-general in the Danubian Principalities, Minister of the Interior, and Minister of Foreign Affairs. He resigned this office in 1853, being opposed to the Russian policy of the time, but returned to it, and became in 1861 Grand Vizier. Throwing up his post in two years, he became Minister of War, returning however in 1867 to his old office of Minister of Foreign Affairs. He died at Nice, whither he had gone for the benefit of his health, February 11, 1869. F. was extremly popular on account of his knowledge of European languages and customs, his personal amiability, and his brilliant diplomatic powers. He published a *Turkish Grammar* in 1852, and was one of the earliest members of the Turkish Academy of Literature and Science. During the Eastern crisis he wrote a pamphlet, *La Vérité sur la Question des Saints Lieux* (1853), which irritated the Czar as much as it pleased his countrymen.

Fuca'ceæ, or **Melanosper'meæ**, a division of the great natural order *Algæ* or seaweeds. They include the brown-coloured seaweeds, or marine plants of an olive-green or brown colour composed of multicellular fronds. The fructification exists in the form of *conceptacles*, which contain moving cells. The typical genus is *Fucus*, and a large number of genera and species are included in the group. Most of the F. are provided with air-receptacles enabling them to float on the surface of the water. To the F. belong the tangles (*Laminaria*) and many other well-known Algæ—the genera *Sargassum* (Gulf weed), *Halidrys*, *Padina*, &c.

Fuca, San Juan de, Strait, between Washington Territory, U.S., and the S. shore of Vancouver's Island, leads from the Pacific to the Gulf of Georgia, is 60 miles long, and has a breadth of 10 miles. The possession of the largest of several islands in the strait, San Juan, was disputed by Great Britain and the United States, and was awarded to the latter on the arbitration of the Emperor of Germany in 1872. The strait was discovered by the navigator Juan de Fuca in 1592.

Fu-Chow-Fu ('happy city'), the capital of the province of Fu-Kien, China, on the river Min, 25 miles from its mouth. It has a good harbour, and is surrounded by old walls 30 feet high, 12 feet thick, 6 miles in circumference, and surmounted by many towers. The river, which is here crossed by a bridge of 40 or 50 arches 12 feet wide and 1200 feet long, presents a curious, lively appearance with its junks and floating houses. F. has a large arsenal on a European plan, which was founded in 1867, is superintended by a Frenchman, and employs fifty European engineers and teachers and some 1200 Chinese workmen. The city was opened to foreign commerce in 1842, and has a great tea trade. In 1872–73, 75,000,000 lbs. of tea were exported—50,000,000 to Great Britain, 17,000,000 to the colonies, and 8,000,000 to America. In 1874 the total value of imports from foreign ports, including Hong-Kong, was £1,332,388; of the exports, £4,397,321; while the number of British and other foreign vessels that cleared the port was 254 of 164,355 tons. The business of foreign houses is confined to ship brokerage, to the export of tea, and the import of opium, and lead for lining tea-chests. Native merchants import all the cotton and woollen goods from Hong-Kong. Some 500 vessels of 250,000 tons clear the port yearly. F. is noted for its lacquer-work, the making of which is the secret of a single family. Estimated pop. 600,000.

Fuchs'ia, a well-known genus of plants included in the natural order *Onagraceæ*, or that of the evening primroses. Many species and varieties of these beautiful and favourite plants are known, the process of cultivation causing them to exhibit many remarkable variations in colour. The fuchsias are remarkable for having a *coloured* and funnel-shaped calyx. The fruit is a four-celled *berry*. These plants are of moderate size. Their original habitat was S. America and the S. parts of N. America. The cultivation of fuchsias has largely increased, owing to the readiness with which they can be grafted and propagated by cuttings. The *F. gracilis*, *F. coccinea*, *F. globosa*, and *F. longiflora* are well-known species grown in hothouses.

Fuci'no, Lago di (*Lacus Fucinus* of the ancients), formerly a lake of S. Italy, in the Central Apennines, province of Aquila, 2181 feet above the sea. It had no natural outlet, and its sudden risings often proved disastrous to the ancient Marsi and to their descendants. In the reign of the Emperor Claudius, Monte Salviano was pierced with a tunnel (*emissarius*) 3½ miles long (1⅝ through solid rock) to let off the surplus waters. The completion of this work, in which some 30,000 men were employed for eleven years, and which is only inferior to the Mont Cenis Tunnel, was celebrated by a gladiatorial naval contest attended by vast numbers, A.D. 52. There were, however, serious defects in its construction, and despite the efforts of Trajan and Hadrian it gradually became choked up. Many vain attempts were made to reopen it, and the waters continued steadily to rise. In 1852 the Italian Government made a grant of the basin of the lake to a company on condition that they should drain it, a privilege subsequently sold to Prince Torlonia of Rome. Eventually the work of clearing and improving the old channel was completed in 1862, after an outlay of £1,200,000. Some 36,000 acres of good corn land were reclaimed, but the work was then abandoned for a time, partly on account of the valuable fisheries, chiefly because of the enormous expense of draining the deeper S. end of the lake. In 1861 its circumference was 37 miles, and its depth 60 feet; these numbers were reduced to about one-third in 1871. At last in 1874 the drainage was completed, and 45,000 acres in all reclaimed. The neighbourhood is dotted with charming antique villages. To the N. rises abruptly from the plain the double-peaked Monte Velino (8792), visible from Rome.

Fu'cus. See FUCACEÆ.

Fu'el, a term applied to 'substances which may be burnt by means of air with sufficient rapidity to evolve heat capable of being applied to economical purposes' (Dr. Percy, *Metallurgy*, vol. i.). Numerous and different as these substances are, they all owe their special properties as F. to the presence of two elements only, carbon (C) and hydrogen (H). The chemical and physical properties of the various fuels will be found described under the headings COAL, COKE, PEAT, &c. We shall here consider their economical employment in relation to the theory of combustion.

In combustion the C or H combine with oxygen (O), and the combustion is said to be 'perfect' when combination takes place with the maximum amount of O with which the element can form a stable compound. The perfect combustion of C produces carbonic acid (CO_2); and of H, water (H_2O). The *calorific power* of a F. is the quantity of heat (in thermal units or in foot pounds) which can be developed by the *perfect* combustion of one unit of weight of it; it is independent of the *rate* of combustion. *Calorific intensity* (in degrees) is the thermometric effect of the same combustion, and is thus proportional in the same body to the rapidity with which the combustion takes place. Taking 1 lb. as the unit of weight, the calorific power of C is about 14,500 thermal units (*i.e.*, 1 lb. of it, in combining with 2⅔ lbs. of O to form CO_2, will develop sufficient heat to raise 14,500 lbs. of water 1° F.); and of H, about 62,000 thermal units. If 1 lb. of C undergo an *imperfect* combustion and be converted only into carbonic oxide (CO) instead of CO_2, only 4452 thermal units will be developed, *i.e.*, the calorific power will be reduced to less than one-third its former value. The importance of this will appear shortly. It may be noted here that the calorific power is *not* proportional to the quantity of O combining, as has often been stated.

If the required quantities of C and O were simply brought together and caused to combine, and the whole heat of combination were spent in raising the temperature of the CO_2 produced, the resulting calorific intensity would be 18,329° F. (supposing the pressure to be kept constant during the operation). The calorific intensity of the combustion of H, calculated in the same way, would be 12137°; and of C converted into CO, only 7697°. If the O were supplied in the form of air, the other conditions remaining the same, the temperature would be reduced, because of the quantity of nitrogen (N) which would have to be heated along with the other gases. The resulting calorific intensities would in this way be reduced to 4892°, 4831°, and 2674°.

The assumption here made that the whole heat generated by the combustion should be expended in raising the temperature of the gases produced is obviously not one of which the fulfilment would be desirable. The object of the combustion is generally to raise the temperature of some substance or object placed near or in contact with the F., and not that of the gases produced. We may examine the effect of this upon the available calorific power and intensity in the case of the furnace of an ordinary steam boiler. Here the escaping gases are required to be somewhat hotter than the air when it enters the furnace, in order to create a draught. This difference of temperature may be about 500° F. All the heat but what is required to create this rise of temperature should be absorbed by the water in the boiler, this absorption reducing the gases from the high temperature of the furnace to the required limit as they pass along the flues. By a simple calculation it can be shown that the heat available under these circumstances for heating the water will be—for each pound of C converted into CO_2, 13,000 thermal units; for each pound of H converted into H_2O, 47,000 thermal units; and for each pound of C converted into CO, 3600 thermal units. The usual standard of evaporative power is the number of pounds of water at 212° which one pound of the given F. will convert into steam of the same temperature. Each pound of steam so formed requires 966 thermal units for its formation, so that, dividing the quantities already given by 966, we obtain the following results:—

Combustion of	Number of pounds of water at 212° converted into steam of the same temperature by the combustion of one pound of F.	
	Total.	Available after raising gases 500°.
C into CO_2.	15·06	13·52.
C into CO	4·61	3·75
H into H_2O.	64·21	48·72.

The assumption is very commonly made that the calorific power of any F. containing known quantities of C and H can be found at once from data such as those just given. This involves the assumption that every pound of C or of H in the coal will behave in its combustion just as it would were it by itself. This assumption has not been verified by recent experiments, which have shown in many cases (*a*) that the calorific power of particular specimens of coal measured in the Calorimeter (q. v.) was considerably *greater* than that found by calculation from the percentage of C and H which they contained; and (*b*) that the calorific power of fuels having the same analysis often differs considerably. The cause of this may probably lie in the fact that as yet we are almost entirely ignorant of anything but the *ultimate* constitution of coal and other fuels; their *proximate* constitution, the way in which their constituents are combined among themselves, we know next to nothing of. In the absence of further experiment, it is at the same time often accurate enough for practical purposes to find the evaporative power of a unit of weight of any given F. by multiplying the quantities of C and H in it—expressed as fractions—by constants such as those given in the table above. It must be remembered that if there be any O in the F., only as much of its H must be considered available as F. as is *in excess* of the amount required to form water by combination with that O.

In practice no F. reaches such a high evaporative power as that given in the table above. The principal reasons for this are the following:—

(*a*) Radiation takes place from the boiler and the furnace; heat is wasted in heating the 'ash' or incombustible residue of the F., and is lost with the falling ash and cinder. These causes of loss cannot be entirely prevented, but by covering the boiler with non-conducting material and managing the fire carefully they can be kept within small limits.

(*b*) From $1\frac{1}{2}$ to 2 times the net quantity of air required has to be passed through the furnace in order that sufficient O may come into contact with every portion of the F.; the whole of this air has to be raised to the temperature of the escaping gases. Considerable loss from this cause is unavoidable; it can in general only be reduced to a minimum by careful trials in each particular case.

(*c*) Some portion of the C passes away incompletely oxidised, *i.e.*, converted only into CO instead of CO_2. If the F. be in a tolerably thick layer, the CO_2 formed at the lower part of it will be converted into CO (by combination with another equivalent of C) as it passes upwards; and if there be a deficiency of air at the top of the F., it will pass away in this state.

(*d*) The compounds of H and C (hydrocarbons) which occur in many bituminous coals, and which are volatilised at an early stage of the combustion are decomposed if raised to a high temperature with any deficiency of air, and their C is deposited in the flues, &c., on cooling, as soot.

The last two causes of loss are both serious; they can only be obviated by a very careful adjustment both of the quantity of air admitted, the part of the furnace (above, below, at the side of, or behind the F.) at which it enters, and the time at which it is admitted. The hydrocarbons, for instance, require for their perfect combustion a considerable quantity of air entering above the F.; but they are all burnt within a short time after each supply of fresh F. is put on the grate; and after this such a quantity of air, if it were still to be supplied, would have no further result than to cause loss as mentioned at (*b*).

A F. of which the calculated calorific power is equivalent to the evaporation of about $15\frac{1}{2}$ lbs. water from and at 212° may in exceptionally favourable circumstances evaporate as much as 12 lbs. in a very efficient boiler, but 10·5 lbs. would be considered very good work, and engineers are often contented with much less. With inferior fuels the evaporation is often as low as 5 or 6 lbs. of water per 1 lb. of coal.

Fuel, in law. See TURBARY, COMMON OF; FEAL AND DIVOT (Scotch law).

Fuen'te de Oveju'na (*i.e.*, 'the sheep's fountain,' so named from its springs), a walled town in the province of Cordova, Spain, on a hill between two tributaries of the Guadiata, 45 miles N.W. of Cordova. It has linen, woollen, and leather industries, and near it are several coal-mines. Pop. 5500.

Fuen'tes de Ono'ro (*i.e.*, 'the fountains of honour'), a Spanish village on the Portuguese frontier, and in the province of Salamanca, 14 miles W. of Ciudad Rodrigo, celebrated as the scene of a fiercely-contested battle between the English, commanded by Wellington, and superior numbers of the French under Massena, which terminated the French invasion of Portugal, 5th May 1811.

Fu'ero (from Lat. *forum*) is a Spanish word primarily meaning a place of justice, and then the customary law administered there. It is now confined to the rights and privileges of municipal constitutions of provinces and towns in the Basque provinces, including Navarre. The Visigothic code of Spain, collected by Egiza, 687–701, is called the *F. juzgo*. It is to some extent territorial in its character. It recognises slavery; a man may not marry a woman older than himself; the *arras* is the same as the Latin *dos* and German *morgengrab*; the *patria potestas* is asserted, and divorce is granted for adultery only; sexual crimes are severely punished. To this succeeds the period of many provincial and local customs, *e.g.*, *F. de Leon*, collected by Alfonso V. in 1020; *F. viejo de Castilla* (known also as *F. de hijos dalgo, libro de los jueces*), published by Pedro of Castile; *F. de Sobrarbe* of Aragon; and a crowd of *fueros municipales*—as of Salamanca, Toledo, Leon, Naxerd. Many singular institutions are contained in these fueros; they recognise, for instance, concubinage for life, settled by written contract, the concubine being entitled to bread, table, and knife (*a pan, mesa, e cuchello*). The F. of Plasencia goes so far as to say that the *barragania* who has been faithful has right to one-half the acquired property of her paramour. The amount of dowry on marriage is publicly regulated by many of the fueros. In Leon and Castile the rare custom of *gananciales* obtained, *i.e.*, all acquired property was divided equally between the spouses. There is also found a usage named *unidad*, by which the surviving spouse, *so long as not re-married*, has the possession of the whole estate. The bachelor suffers many penalties; he cannot give evidence nor acquire burghal rights. After this comes a period of consolidation, beginning with the *F. viejo*, known as the Statute of Burgos or Castile. Then comes the *F. real* of Alfonso the Wise, followed by the *partidas*; Isabella and Ferdinand published the eighty-four *Leyes de Toro* (7th March 1505). The final consolidation was by Philip II., in the famous *Recopilacion de las Leyes*. The *F. juzgo* and the *partidas* were also in force in Portugal. As already stated, however, greater interest attaches to the 'political' part of the fueros, especially in Biscaya and Navarre, in which districts their consolidation is traced to Count Juan in 1371 and King Theobald in 1236 respectively. In Biscaya there is a Junta General, meeting yearly; and the executive consists of a corregidor, with six regidores, together forming the regimiento. The King of Spain is entitled only to the name of Senor. In Navarre, again, there is a Great Council and a Contaduria, or Chamber of Finance. The Basque provinces claim exemption from military service, from direct land-taxes collected for the national treasury, and from the tobacco monopoly and other customs regulations. To such claims the Spanish Government has always been bitterly opposed; hence the support received by Don Carlos from the Basque people, who have besides a peculiar language and a territory separated from the rest of Spain. To the spirit of local management shown in the Basque *juntas forales*, and which has produced better charities, prisons, and roads than any other portion of Spain, the central Government has not recently been opposed. Spanish politics are in a state of continual fluctuation, but in the constitution of 1869 at least great prominence was given to the powers of *diputaciones provinciales* and *ayuntiamentos* (or municipalities).

Fuer'te de Andal'gala, a town in the province of Catamarca, Argentine Republic, near which are rich copper-mines. Pop. 5000.

Fuer'te Ventu'ra. See CANARIES.

Fugg'er, Family of, a race of merchant princes, were early admitted amongst the hereditary nobility of Germany. The founder of the family, Johann F., made a small fortune as a weaver at Graben near Augsburg. His eldest son, also named Johann, was a leading man amongst the weaver burgesses of Augsburg about 1370, and at his death in 1409 left 3000 florins. This sum was used to such purpose by his son Andreas that he was soon known as 'the rich F.;' for as a money-lender he had begun the business which was destined to establish the brilliant fortunes of the family. Andreas' three nephews, Ulrich (1441–1510), Georg (1453–1506), and Jakob (1459–1525), were ennobled by the Emperor, and were able on one occasion to lend Maximilian 170,000 ducats. But it was under Karl V. that the splendour of the family culminated. The brothers Anton (1493–1560) and Raimund (1489–1535), sons of Georg F., were made counts of the empire, and were permitted to coin gold and silver. Anton left a fortune of 6,000,000 crowns of gold. Both brothers were zealous Catholics. Their descendants were further favoured by Ferdinand II., under whom they held the highest offices of the state, while still continuing their commercial speculations. They were munificent patrons of art and science, and were zealous benefactors of the poor. Both of the branches which still boast the name of F. have long since given up commerce. The present representative of the line of Raimund is Count Raimund F., born 29th June 1810; and of Anton, Count Philipp F., born 9th November 1820. A collection of the portraits of the most important members of the family was published at Augsburg in 1593 (2d ed. enlarged, 1618; 3d ed. still further enlarged, at Ulm, 1754).

Fugita'tion, in Scotch law, is a sentence pronounced against one who does not obey a citation to answer a criminal charge. One of its consequences is Escheat (q. v.). The similar sentence in England is outlawry.

Fu'gleman (Ger. *flügelmann*, 'a file-leader,' from *flügel*, 'wing'), a soldier specially expert and well trained, who is placed in front of a rank on drill, as an example for time and movement in the ordinary exercises.

Fugue', in music (probably from the Lat. *fuga*, 'a running away or chase'), a composition in which a phrase is given out by one part alone, and afterwards taken up and repeated or imitated

by the others, so that the different parts seem to fly from and pursue each other alternately. The earliest specimen of this imitative music which has come down to us is a canon composed by Guillaume Dufay, a Belgian, who was chapel-master and a tenor singer in the Papal Chapel at Rome from 1380 to 1432. After his time it developed—gradually at first and afterwards rapidly—until it became in the 18th c., the era of Bach and Handel, the principal form in which the greatest composers expressed in music their noblest thoughts. Before the time of Haydn, Mozart, and Beethoven, music was looked upon rather as a combination of melodies than as a succession of chords, and from that point of view the F. was the highest form which a composition could take. Composers have now better means—means more capable of varied expression, and less formal and rigid—of expressing their ideas, so that the F. has been displaced from its ancient superiority; but as the form in which so much of our finest music is written, it can never lose interest to us. Even now it is used in the choruses of oratorios and masses, where, probably through long familiarity, it not only does not seem antiquated, but appears most suitable and natural. The F. has many forms. A F. in four parts, with a single subject, is in its simplest form arranged somewhat as follows:—One of the parts commences with a melodic phrase called the *subject*, in the principal key, and is shortly answered by another part (the choice of parts is arbitrary) giving out the same subject in one of the two most nearly related keys. This is called the answer, and is accompanied by a continuation in Counterpoint (q. v.) of the part which commenced. At a suitable point the key is changed back to the original one, and the third part enters with the subject in its first form, to be answered in its turn by the fourth in the same key as the second. Throughout the rest of the F. the subject and answer form the leading melodic ideas, appearing in different parts in different forms and in different keys, and accompanied by new counterpoint, as well as by the original counterpoint varied in an endless number of different ways.

The form we have described is only one of many which the F. takes, and for all of which the older musicians have laid down countless rules. In the *strict* F. the one subject and counterpoint are closely adhered to, and every rule rigidly observed; in the *free* F. episodes are introduced, and subsidiary themes only indirectly connected with the subject. There are also fugues with two subjects, double fugues, in which two subjects are treated simultaneously, and so on. The older composers were fond of showing their extreme ingenuity in manipulating the F. without transgressing rules; they inverted the subject, imitated it at all kinds of odd intervals, repeated it with its notes doubled in length or halved in length, and in many other ways twisted and turned it about so as to be almost unrecognisable. In the hands of ordinary musicians the result was merely the production of a mechanical curiosity; a F. came to be judged by its ingenuity, and not by its musical merit. Strangely enough, one of the most whimsical of oddities occurs in a sonata of Beethoven's (*Opus* 106, *finale*), where the subject, a very florid one, is absolutely *reversed*, that is, played backwards, note by note.

In the oratorios of Bach and Handel fugal writing reached its highest development; it has not been taken up, except to a very limited extent, by any of the great composers since their time. Bach has left also a collection of fugues for the pianoforte (*das wohltemperirte Clavier*), which will probably last as long as the instrument on which they are played, as fresh and interesting as if they had been written yesterday.

Füh'nen (Dan. *Fyen*), next to Seeland, the largest of the Danish islands, is separated from Jutland and Slesvig by the Little Belt, from Seeland by the Great Belt, and forms a province together with the small islands Langeland and Arröe, having a total area of 1148 sq. miles, and a pop. (1874) of 215,900. F. is 55 miles long and 45 broad, and has a rich level surface, rising in slight elevations to the S., while the coast is greatly indented by fjords. The longest river is the Odense-Aa (40 miles); of the lakes the Arreskov-See is specially rich in fish. F. exports barley, buckwheat, oats, flax, hemp, horses, cattle, honey, &c. Among the chief towns are Odense, Svendborg, Nyborg, and Assens (pop. 3461). The havens possess (1874) 315 vessels, of 31,366 tons. Langeland, formerly Lafvind, is 30 miles long and 5 broad, is well wooded in the N., and has a fruitful surface.

Fu'-Kien ('consummation of happiness'), one of the richest provinces of China, is bounded E. by the sea, N. by Chi-Kiang, W. by Kiang-si, and S. by Quang-tung, and has an area of 45,761 sq. miles, and a pop. of 22,799,556. It is bordered on the W. by the Tajü-ling range, has an undulating surface, and is mainly watered by Min river, yielding plentiful crops of tea, rice, and tobacco, besides the orange, li-chi, olive, plum, pomello, plantain, mulberry, &c. F. includes Formosa (q. v.). Its chief ports are Fu-Chow-Fu and Amoy.

Fu'lahs. See FELLATAHS.

Ful'crum is the fixed point round which a Lever (q. v.) acts.

Ful'da (anc. *Buchonia*, or *Buchgau*), a walled town in the Prussian province of Hessen-Nassau, on the F., a tributary of the Werra (90 miles long), 60 miles N.E. of Mainz by railway. It has a beautiful modern cathedral, the fourth church that has occupied the site, and within which is the shrine containing the body of St. Bonifacius, who was murdered by the Frisians in 754. There is also the palace of the former prince-bishops, the church of St. Michael (822), a Roman Catholic seminary, a public library, and an arsenal, besides manufactures of fine linen and woollen fabrics, leather, earthenware, tobacco, beer, vinegar, &c. F., the capital of the former grand duchy of F., was joined to that of Frankfurt by Napoleon in 1810, but in 1815 was ceded to Prussia and transferred to Hessen-Cassel, which in 1866 was annexed by Prussia. Pop. (1872) 9470.

Ful'gurites (Lat. *fulgur*, 'lightning') are vitrified tubes formed through the fusion of sand by the passage of lightning.

Fulham, (lit. 'the dirty place'), formerly an isolated village and parish of Middlesex, on the left bank of the Thames, and 4 miles S.W. from Hyde Park Corner, London, is now included in London without the walls, of which it forms a semi-suburban district.

Ful'ica. See COOT.

Fulig'ula. See POCHARD.

Full'er, Andrew, an able theologian, was born at Wicken, Cambridgeshire, England, February 6, 1754. He was of humble origin, and received only a limited education. When sixteen years of age he became a member of a Baptist church. Showing special gifts, he was ordained over the Baptist church in Soham, in 1775, on the small stipend of £21. He removed to the Baptist church in Kettering, Northamptonshire in 1782. In 1792 he assisted in the formation of the Baptist Missionary Society, and as its secretary rendered it signal services (without pay). In theology he was a moderate Calvinist, and his hand was often against both Socinians and hyper-Calvinists. The degree of D.D. was offered to him in 1793 by New Jersey College, U.S., and in 1805 by Yale College, U.S., but declined. He died May 7, 1815. He was noted for his sagacity and common sense, and has been called the 'Franklin of theology.' His chief works are *The Calvinistic and Socinian Systems* (Lond. 1794); *Socinianism Indefensible* (Lond. 1797); *Sandemanianism; Memoir of S. Pearce of Birmingham*; and *Expository Discourse on Genesis* (Lond. 1806). They have been frequently reprinted both in England and the United States. See the memoir of F. in the complete edition of his works by A. G. Fuller (Lond. 1846).

Fuller, Margaret, born in Cambridge Port, near Boston, Massachusetts, 23d May 1810, was the eldest daughter of a successful and highly-educated lawyer, who taught her himself. She read Latin at the age of six, and suffered the penalty of too much brain stimulation, becoming a somnambulist and a ghost-seer. After the classics, her father's library had chiefly the English writers of Queen Anne and the French writers of the Aufklärung, and so her mystic and imaginative nature was soon clad 'with that coarse but wearable stuff woven by the ages—common sense.' Her mother's flower-garden, and the view of distant hills, 'beyond which she placed her paradise,' were the chief sources of her finer experience, until one Sunday evening she wilfully disobeyed her father by reading Shakespeare, who was soon followed by Cervantes and Molière. 'The first angel of her life' was an English lady, a painter and musician, 'a *millefleur* beauty, the distilled product of ages of European culture,' who made up for much of the hard and superficial tone of New England village society. F. herself has described in *Mariana* her

few years at the school of Dr. Parkes, Boston. In 1837, after her father's death, she became principal teacher in the Green Street School, Providence, Rhode Island, where she taught to boys and girls philosophy, rhetoric, history, poetry, and moral science. During 1839-44 she edited the Transcendentalist *Dial*, to which she contributed many striking articles. She loved gems, ciphers, talismans, omens, coincidences, drawing lots, anniversaries, dreams; she was the disciple of Swedenborg and Rosenkranz; she believed in fate, guardian genii, mesmerism. She wrote epistles to Beethoven as her patron saint. At the same time she was perfectly devoted to truth, and offended many by the plainness of her speech. In 1846 appeared her *Papers on Literature and Art.* During a tour in Europe she met at Rome the Marchese Ossoli, whom she married in December 1847. She spent the stirring times of the revolution at Rome. Her *Woman in the Nineteenth Century* (Lond. 1850) was one of the earliest vindications of the 'rights of women.' On 16th July 1850 the Marchesa, her husband, and their only child were drowned off the coast of Long Island. The magnetic flash of her eyes, and the marvellous grace of her head and neck, are still remembered by her friends. See *Memoirs of Margaret F., Marchesa Ossoli* (1852). A new edition of her complete works was published at Boston in 1874.

Fuller, Thomas, D.D., an English divine and historian, born in 1608, was educated by his father, the rector of Aldwinkle, Northamptonshire, till he was twelve years of age. He was then sent to Cambridge, where he took orders in 1630. Shortly after he was presented to the living of St. Benet's, Cambridge, in which he gained great popularity as a preacher. The following year he obtained a prebendal stall in Salisbury Cathedral and a fellowship in Sidney Sussex College. He was next chosen rector of Broad Windsor, Dorset, and in 1640 lecturer at the Savoy Church, London. During the Civil War he shared the reverses of the Royalists, to whom he adhered; but in 1646 he was chosen lecturer at St. Clement's Lane, Lombard Street, and then at St. Bride's. About 1648 he was presented to the living of Waltham, Essex, and in 1658 to that of Cranford, Middlesex. Shortly before the Restoration he was reinstated in his Savoy lectureship and his stall at Salisbury; and soon after that event he was made one of the king's chaplains and D.D. He died 16th August 1661. His principal works were a *History of the Holy Warre* (1639); *The Holy and Profane State* (1642), one of the most characteristic of his writings; *A Pisgah Sight of Palestine* (1650); *The Church History of Britain* (1655); and *The Worthies of England* (1662), which is the best-known and most popular of all his productions. 'The quips and conceits of F.'s style represent the later Euphuism in its best form, for F. had religious feeling and high culture, good-humour, liberality, quick sense of character, and lively wit, which the taste of the day enabled him to pour out in an artificial form, with a complete freedom from affectation. Culture and natural wit make his quaintness individual and true' (Morley's *English Literature*). See Russell's *Memorials of Thomas F.* (1844), and J. E. Bailey's *Life* (Lond. 1874).

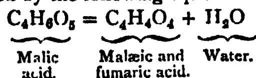
Fuller's Earth, a soft, greasy, detergent, earthy clay, formerly much used in the *fulling* or cleaning of woollen cloth from grease, hence its name. It is a hydrous silicate of alumina, having oxide of iron, lime, magnesia, and soda as impurities; in colour it is green, greenish yellow, or blue; it falls to powder in water, and with great heat it melts. F. E. is found in many localities in England, in the Oolitic and Cretaceous systems; and at Nutfield, near Reigate, Surrey, it is extensively worked.

Ful'mar, or **F. Petrel** (*Procellaria glacialis*), a species of Natatorial birds included in the family *Procellaridæ*, and found in large numbers at St. Kilda and other parts of the N. islands and coasts. It is also common in the Arctic regions, and feeds on the blubber of whales, on barnacles, shellfish, &c. The F. is coloured white on the head and belly, and pearl grey on the back. The hinder toe (as in all the *Procellaridæ*) is deficient and rudimentary; the first quill is the longest in the wings. The average length of the bird is 20 inches. The F. affords oil to the inhabitants of St. Kilda, who also value the eggs and down. A single egg of white colour is laid in a nest formed merely of a hollow in the turf.

Fulmin'ic Acid and the Ful'minates. The fulminates, as their name indicates, are explosive compounds. They are formed by the action of alcohol on the nitrate of a metal in presence of free nitric acid. Fulminate of mercury is largely employed as a detonating compound, principally in the manufacture of percussion caps. To prepare it mercury is dissolved in nitric acid and alcohol is added. A violent action takes place, and dense white fumes are evolved, the fulminate of mercury eventually subsiding as a white powder, which is purified by washing with cold water. Fulminate of silver is obtained in much the same manner, substituting silver for mercury: it is even more explosive than the mercury compound. Fulminate of mercury has the composition represented by the formula $HgC_2N_2O_2$, and fulminate of silver by the formula $Ag_2C_2N_2O_2$. F. A., which has never been obtained, and which is therefore hypothetical, would be represented by the formula $H_2C_2N_2O_2$. The fulminates are isomeric with the decyanates, and the salts of fulminaric acid ($H_3C_3N_3O_3$)—a derivative of F. A.—with the cyanurates. See ISOMERISM.

Ful'tah, or **Fal'da** (*Falta*), a village in the district of the Twenty-four Pergunnahs, Bengal, British India, 22 miles S. of Calcutta, near the mouth of the Hooghly, the site of an old Dutch factory, and known in history as the spot to which the English survivors retreated after the capture of Calcutta by Seraj-ûd-Dowlah in 1756.

Ful'ton, Robert, an American engineer and inventor, was born at Little Britain, Lancaster county, Pennsylvania, U.S., in 1765, although recently (1876) it has been contended that he was born at Beith, Ayrshire. Although at the age of three he lost his father, and received only a common school education, so earnestly did he give himself up to what he conceived to be his true vocation as artist and jeweller, that before he was twenty-one he was able to place his mother in a small farm. Going to London to study art, he was persuaded by the Duke of Bridgewater, whose patronage as well as that of Earl Stanhope he obtained, to become a civil engineer, and devoted himself in future entirely to mechanical invention. The early period of his career in England was marked by his invention of machines for spinning flax, making ropes, and sawing and polishing marble. Receiving a patent (1796) for canal improvements, he proceeded to Paris. His visit to France was rendered remarkable chiefly by his attempts to render perfect his scheme of steam navigation—on which he had been induced to enter chiefly by Lord Stanhope, if not by Watt—and his invention of a submarine boat called *Nautilus*. F.'s inventions, however, were not favourably received either in England or in France, and in 1806 he returned to his native country, where, after considerable difficulties, he succeeded in having the cost of his experiments with torpedoes defrayed by the Washington Government. Finally, with the help of Robert R. Livingston, U.S. minister at France, whose acquaintance he had made at Paris, into whose family he married, he was enabled to launch successfully a steamboat named the *Clermont* on the Hudson, in 1807. After this, although F. never made much money, his career was very successful, culminating (1814) in the construction of a new steamer, named first *Demologos* and afterwards *Fulton the First*, by which he may be said to have done for steam navigation what Watt did for the steam-engine. He died February 24, 1815. See Colden's *Life of R. F.* (1817).



Fu'mage (from Lat. *fumus*, 'smoke') is a tax mentioned in Domesday on every house having a chimney or fire-hearth. By 13 and 14 Car. II. c. 10, a tax of two shillings on each hearth paying to church and poor was granted to the king. The tax was abolished in the reign of William and Mary.

Fumaria'ceæ, a natural order of Exogenous plants, commonly named the Fumitory order, and represented by the common fumitory (*Fumaria officinalis*), and by a species of the genera *Diclytra*, *Corydalis*, &c. They have brittle stems and a watery juice; the leaves are alternate and exstipulate, and the flowers irregular and unsymmetrical. The sepals are two, and are deciduous; four cruciate irregular petals are developed. The stamens may number four when they are polyandrous, or six when united into two bundles (*diadelphous*). The fruit is a round indehiscent *nut*, or a pod composed of one cell and two valves. The fumeworts occur typically in temperate regions in the northern hemisphere. All have bitter and acrid properties. Some (such as *Diclytra spectabilis*) are showy, and are cultivated as hothouse plants. Common fumitory is a garden and field weed.

It was formerly held in esteem as a cure for scrofula, and as possessing tonic properties.

Fumar'ic Acid is obtained, along with its isomer malæic acid, by heating Malic Acid (q. v.). The change which occurs may be represented by the following equation :—

$$C_4H_6O_5 = C_4H_4O_4 + H_2O$$

It has no practical importance.

Fu'migating Pas'tils are composed of various odoriferous ingredients, in combination with charcoal and nitrate of potash, which, while smouldering slowly, evolve agreeable odours. F. P. may be prepared thus :—Benzoin and dry balsam of Peru, of each 16 parts ; yellow sandalwood, 4 parts ; labdanum, 1 part ; charcoal of limetree wood, 96 parts ; nitrate of potash, 2 parts ; and mucilage of tragacanth, sufficient to form a pasty mass, which is then put into conical moulds and dried. The odoriferous materials may be varied indefinitely, but the relative proportions should be maintained. The 'ribbon of Bruges' is also employed for the same purpose, and is prepared as follows :—Dissolve two ounces of nitrate of potash in a pint of water, and steep in it undressed cotton tape ; dry the tape and steep it in a strong aromatic tincture and dry. The aromatic tincture may be of any odour or of any combination of odours desired. When the fumigating pastil or the ribbon of Bruges is kindled, it burns slowly like match-paper ; and by regulating the quantity of nitrate of potash, combustion may be slow or quick as desired.

Fumiga'tion (Lat. *fumigatio*, from *fumus*, 'smoke'), the employment of fumes or vapours to purify articles of apparel and goods or apartments supposed to be imbued with some infectious or contagious poison. Formerly pastils were used for such purposes, but they merely disguise disagreeable smells without destroying the disease-germs. Since the recent discovery of the germ-origin of diseases of the zymotic type, or of those which are contagious and infectious, the value of F., or aerial disinfection, as it should be called, has been submitted to the test of rigid experiment, and valuable results have been obtained. Aerial disinfection, as commonly practised in the sick-room, is useless or positively objectionable, owing to the false sense of security which it gives ; for to make the air of a room smell strongly of carbolic acid or of chlorine is, so far as the destruction of specific contagion is concerned, an utterly futile proceeding. For purposes of sanitary F. the dioxide of sulphur, which is simply the fumes of ignited sulphur, is by far the most reliable and the most accessible. For an exhaustive examination of the subject, see Dr. Baxter's *Report of an Experimental Study of Certain Disinfectants*, in *Reports of the Medical Officer of the Privy Council and Local Government Board* (New Series, No. vi 1875).

Funar'ia, a genus of Mosses (q. v.), and the type of a small natural order, characterised by its vesicular calyptra, which becomes sabulate above. *F. pygrometrica* is very common on charred and burned soils in this country, and occurs all over the world.

Funchal' (Port. 'a place abounding in *funcha*' or fennel), the sole town and port of the island of Madeira, and the capital of the Portuguese province composed of the islands of Madeira and Porto Santo, lies at the base of a picturesque mountain nearly 4000 feet high. It extends for a mile along the S. shore, and up the sides of the mountain in scattered villas for 2000 feet, ending in the double-towered church of 'Our Lady' (*Nossa-Senhora*). F. has a cathedral, many churches and convents, several forts, &c. Its appearance from the sea is magnificent, but the interior of the town in no way corresponds to the effect of the external view. The roadstead is exposed and the anchorage rocky. F. is a favourite residence for English people suffering from pulmonary complaints, and English modes of life and the English tongue may almost be said to prevail. F. is the coaling station for the West African and East Indian (Cape route) trade. Pop. (1877) 16,776.

Func'tion, a mathematical term of frequent occurrence, derived from Lat. *fungor*, 'I discharge.' One quantity is a F. of another when it depends for its value upon the value of the latter. Thus $y = ax + b$ is a F. of x, and is also of course a F. of a and b. The same is true of $y=ae^{bx}$, $y=a \sin x \cos b$, &c. The first is called an *algebraic* F., while the other two are distinguished as *transcendental* functions, which are easily recognised by the presence of exponental, logarithmic, or trigonometrical symbols. The fact that y is a function of x may be expressed by the notation $y=F(x)$. In the same way $F(y)$ would denote the quantity which involves y in exactly the same way that y involves x. $F(y)$ may obviously be written $F[F(x)]$, or more concisely $F^2(x)$. According to this symbolical notation, $F^m(x)$ signifies m successive operations of the same kind, each operation being performed upon the *result* of the preceding operation. The investigation of the *forms* of functions, without any regard to their values, has given rise to the *calculus of functions*—a branch of mathematics growing in importance. An idea of its nature may be gathered from the following example :—Required the *form* of F, so that the equation $F(x)F(y)=F(x+y)$. The F. is in this case $F(x)=a^x$, where a is any constant. For the general methods of investigation, see Babbage's *Treatise on the Calculus of Functions*, Lagrange's *Théorie des Fonctions Analytiques*, Cauchy's *Cours d'Analyse*, and Peacock's *Algebra*.

Functions, in physiology, the name given to those acts which are performed by animals and plants, and which together constitute the *life* of these beings. Every living organism performs the three great F. of *nutrition*, *reproduction*, and *innervation* ; and according as these are subserved by organs of high or low structure, the being is said to be of a superior or inferior type of organisation. *Physiology* is the 'science of F.,' or that which investigates the manner in which vital actions are performed.

Fund, Consolidated. See CONSOLIDATED FUND.

Fundamen'tal Note, in music, is the root of a chord. It is the lowest note if the chord be in its natural position, but is above some of the other notes in the inversions. See CHORD.

Fun'di, or **Fundun'gi**, a grain botanically known as *Paspalum exile*, grown in the W. parts of Africa, and allied in some degree to Millet (q. v.). It will be found described in the article *Paspalum* (q. v.). At Sierra Leone F. is largely used, either as an addition to stewed meat or in the form of porridge.

Funds. See DEBT, NATIONAL.

Fun'dy, Bay of (Fr. *Fond de la Baie*), on the E. coast of N. America, between Nova Scotia on the E. and New Brunswick and the state of Maine on the W., is 180 miles long from S.W. to N.E., and has an average breadth of 35 miles. It receives the St. John and St. Croix from the W., and at its head it forms the Minas Channel and Chignecto Bay, the latter of which is separated from Northumberland Strait in the Gulf of St. Lawrence by an isthmus only 13 miles in breadth, which it is proposed to cut through with a canal. The tides rise to the extraordinary height of some 70 feet, and render navigation dangerous.

Fu'neral Expen'ses. These, if reasonable, constitute a privileged debt in England and in Scotland, and are consequently payable before other debts. (See EXECUTOR, PRIVILEGED DEBT.) In England, if one dies in debt, the F. E. are usually limited to £10. In Scotland it has been decided (Buchanan *v.* Ferrier, February 1822) that mourning for the widow and children attending the funeral is included in F. E. The reverse has been decided in England (Johnson *v.* Baker, 2 C. and P. 207).

Fünf'haus, a town of Austria, 2 miles N. of Vienna by railway, with manufactures of silks, satins, woollens, red leather, &c., and a population (1869) of 27,065.

Fünf'kirchen (Ger. 'five churches ;' Magy. *Pécs*, 'fives'), one of the oldest towns of Hungary, county of Baranya, on the S. slope of the Mecseg mountains, between the Drave and Danube, 140 miles N.W. of Belgrade, and connected by railway with Agram and Pesth. It is a bishop's see, has the largest and finest cathedral in Hungary, and was formerly the seat of a university. Its manufactures are chiefly woollens, flannels, silks, leather, and ironwares, and it has an active trade in wine, gall-nuts, hogs, &c. There are coal-mines in the vicinity. Pop. (1869) 23,863. F. was held by the Turks from 1543 to 1686.

Fun'gi (Lat. : a cognate of the Gr. *sphongos*, 'a sponge'), the name given to a large group of cryptogamous or cellular

plants, which have neither leaves, roots, nor stems. They are nourished by means of whitish filaments named the *mycelium* or *spawn*, which form a kind of network by their union, and spread out amid the substances in which the F. grow. The mycelium gives origin to various structures which bear the *fructification*, and is itself composed of elongated colourless cells. F. are further distinguished by the fact that *spores* or seed-like bodies are produced, either enclosed within spore-cases or *thecæ*, or destitute of any such protection. Some of these spores named *antheridia* contain actively moving cells or spermatozoids, and seem to represent the *pollen* or male element of higher plants. Other cells, named *archegonia*, are analogous to the ovules or seeds produced by the pistil of flowering plants. The mycelium requires heat and moisture to produce its reproductive elements, and occasionally, as in the Puffballs (q. v.), when favourable conditions are supplied, the tissues of F. may grow with astonishing rapidity. In the spawn of the mushroom rapid growth may be observed to take place. F. grow in very various situations, and the difficulty experienced in following out the different stages of growth has rendered their classification a difficult task. Some are found growing beneath the soil, others on its surface. The Truffles (q. v.), for example, grow below ground, the Mushrooms (q. v.) above. Large numbers are parasites, feeding either upon or within the bodies of other animals and plants. In many animals serious diseases may be produced by the presence and growth of F. Thus the diseases in plants known as smut, mildew, ergot and dry rot, are caused by the growth of F., and the vine and potato diseases have also been traced to fungoid action, the *Peronospora infestans* having been recently traced through all its stages in the production of the potato disease. The Vinegar Plant (q. v.), Yeast Plant, (q. v.), and other familiar organisms exemplify F. developed in fluids, and which tend by their growth to assume putrefactive change. In animals, diseases are similarly induced by the development of F. The silkworms, as was proved by Pasteur in a series of beautiful researches, suffer from a minute fungus which grows and propagates at a rapid rate within the bodies of these larvæ, and is communicated by contact to surrounding animals. Many skin diseases in man and lower animals are traced to fungoid growths, and there can be little doubt that most, if not all, changes of a *putrefactive* nature are either caused or are in greater part induced by the growth of these lower forms of plant life. Many F. can be used for food, and are hence named *esculent F.—e.g.*, the mushroom (*Agaricus*). Poisonous F. may be recognised by being in general *highly coloured*, and by having the surface *spotted* or *scaly*. The flesh or substance is *tough* and contains much *water*. The poisonous species also grow in *clusters* or groups, and usually on wet marshy ground. *Edible F.*, on the other hand, are rarely coloured of bright or marked hues, but are either white or dull brown. They are soft and not particularly watery, and generally grow solitary in pasture and meadow lands. The F. which burn the fauces and are of bitter taste, or which yield a pungent juice, may be pronounced unsafe to eat, even if they be not actually poisonous. Dr. Badham perhaps goes to an extreme when he says that the great majority of F. are edible; but there can be little doubt that many now rejected as poisonous are so treated with little reason. Much may also depend on the nature of the ground and soil. These plants form exceptions to the general rule of plant life, in that they feed on *organic* substances, and probably inhale *oxygen gas* like animals. They have at any rate no power such as that possessed by plants with *chlorophyll* or green colouring matter, of decomposing carbonic acid gas and of emitting oxygen. The classification and arrangement of F. are points on which botanists, from the want of exact data, are not well agreed. One system divides the F. into—(1) *Basidiosporous* or *exosporous* F., or those in which the spores are developed on the outside of sacs named *basidia*; (2) *Thecasporous* F., in which the spores are developed within *thecæ* or spore-cases; and (3) *Myxosporous* F., or those in which the spores are produced in a gelatinous mass of tissue without being enclosed in any definite structure. See *F., their Nature, Influence, and Uses*, by Dr. M. C. Cooke, edited by Berkeley (International Scientific Series, H. S. King & Co., Lond. 1875).

Fun'gibles are in Roman law movable effects which may be estimated by weight, number, or measure, as grain or coin. Jewels and works of art are not F., there being no standard by which they may be valued.

Funn'el (Cymr. *ffynel*, 'an air-hole;' allied to the Lat. *infundibulum*, from *infundo*, 'I pour into'), in steamers, is the iron tube intended to remove the smoke and gaseous products from the furnace without inconveniencing those on the deck, and at the same time to secure a sufficient draught. In ships of war and other large vessels, the funnels are usually made telescopic, so that they can be easily altered in height. F. is also the name of the conical metallic glass or earthenware vessel ending in a tube which is used for filtering or for filling narrow-mouthed vessels.

Furid' Kote (*Farid Kot*), a tributary state of the Punjaub, in India, to the S.E. of Ferozepore district. Area, 600 sq. miles; pop. about 68,000; revenue, about £30,000. The military force is composed of 200 cavalry, 600 infantry and police, and three field-guns. The Rájá holds his territory by a grant dated 1863, by which his independence is considerably limited. The family are of Jat descent, and have uniformly adhered to the British cause.

Furid'pur (*Faridpur*), the chief town of the district of the same name, province of Bengal, British India, on an old channel of the Ganges, 115 miles N.E. of Calcutta. Pop. (1872) 8593. F. is merely a large village, with no important manufactures or commerce.—*F. district* (area, 1524 sq. miles; pop. (1872) 1,012,589) lies at the head of the Delta, just below the junction of the Ganges and the Brahmaputra. It is also intersected by numerous minor streams, which flood the entire country during the rainy season, leaving only the elevated sites of the villages above the water. The soil is extremely fertile. Rice is the staple crop, but pulses, jute, sugar-cane, date and betel-nut palms are grown. Sugar is largely manufactured, both from the cane and the date, and vine-grass mats form a specialty of the district. A considerable trade is carried on by water, and also by the Bengal Railway, whose terminus is at Goalunda.

Furios'ity, a term of Scotch law denoting the kind and degree of insanity which legally disqualifies a person from managing his own affairs. See CURATOR, BRIEVE, IDIOTS AND LUNATICS.

Fur'long (Old Eng. *furlang*, lit. 'a fur or furrow long'), an English measure of length, equal to 220 yards, or one-eighth of a mile.

Fur'lough (Dan. *forlov*, Dut. *verlof*, Ger. *verlaub*, 'leave of absence'), a military term signifying leave of absence. Non-commissioned officers or privates may apply to any officer not below the rank of a captain stationed in the district, or in the absence of such officer to a justice of the peace, for extension of F., which may be granted for a time not exceeding a month, on sufficient cause being shown. For a longer time the approval of the commanding officer of the district is requisite. A man on F. must have a pass, otherwise he may be treated as a deserter.

Fur'neaux Islands, a group of mountainous islets situated at the eastern entrance to Bass Strait, between Tasmania and Australia. Their total area is 513 000 acres, but the population numbers only 242, most of whom are half-castes, who live by sealing and bird-catching. The islands are named after the officer who was next in command to Captain Cook on his second voyage. They belong to Tasmania.

Furnes (Flem. *Veurne*), an old town of W. Flanders, Belgium, situated at the junction of four canals, 4 miles from the sea, and 27 S.S.W. of Bruges by railway. It has a quaint Gothic townhouse, remains of the old abbey of St. Willebrod, is the site of three great yearly fairs, and carries on a large trade in cattle, corn, cheese, linen, &c. Pop. (1870) 4500.

Fur'niture. Household, Law Regarding. Where furniture is lent on hire, as in a lodging-house, the hirer is not liable for damage done by accident, even though the accident be through himself. The tenant is, however, liable for damage arising from his own carelessness, or from his putting the furniture to an improper use. Should damage arise to the tenant from the furniture being insufficient for its proper use, the owner is probably liable in damage to the tenant. Usually all chattels found on the premises may, in England, be distrained for rent (see DISTRESS), the landlord having a right of lien over it. (See LIENS.) In Scotland the landlord has a similar right, called *Hypothec* (q. v.), under which even hired furniture may be seized; but furniture lent without rent cannot be taken. See LODGING-HOUSE, HIRE.

Furruck'ābād (*Farrakhabad*, 'the city of Farrakh Ser,' a Mogul emperor; *Farrakh* = happy), the chief town of the district of the same name, N.W. Province, British India, about 2 miles W. of the right bank of the Ganges, 660 miles N.W. of Calcutta, and 160 S.E. of Delhi. Pop. (1872) 79,204. F. was founded by the Mohammedans in the beginning of the 18th c., and soon acquired great commercial importance; its bankers were especially celebrated, and it retained the metropolitan privilege of a mint as late as 1824. The trade is still considerable, and the streets are wide, clean, and shaded with trees. The elevated mud fort, the palace of the Nawab, still exists, but the British cantonments are at Futtehguih, about 3 miles E. of the town. F. was the scene of an engagement in 1804, when Holkar, at the head of his Mahratta cavalry, was entirely defeated by Lord Lake.—*F. district* forms the centre of the Doab, the triangle lying between the Ganges and Jumna rivers. Area, 1745 sq. miles; pop. (1872) 918,850. Near the Ganges the soil is naturally moist and fertile, and the sandy tract in the interior is now irrigated by a branch of the Ganges Canal (q. v.). The crops are wheat, barley, pulses, maize, sugar-cane, and indigo.

Furrucknugg'ur, a walled town in the district of Gurgaon, Punjaub, British India. Pop. (1868) 10,631. Along with the surrounding country, it formerly belonged to a chief who was hanged for rebellion in 1857. F. is the emporium of the important trade carried on in salt, manufactured in the district by evaporation from wells.

Furruck Shere (Farakh Siyyar), an emperor of Delhi of the Mogul dynasty, who succeeded to the throne by murdering his uncle, Jehander Shah, in 1713, and was himself assassinated in 1718. His reign is memorable for the privileges granted to the British East India Company at Calcutta through the court influence of an English surgeon.

Furs and Furr'iery (Span. *forro*, 'lining'). Fur is a name given to the skins of certain mammalian animals, generally characterized by short, close, and fine hair, prepared for use as human clothing, wrappers, or rugs. Though not generally classed among F., the fine, downy skins of certain birds, as the grebe and the swan, are used in the same way. Furriery is the art of preserving and preparing in various ways such skins for the uses to which they are applied. As F. are primarily valued on account of the protection they afford against cold, it is found that the skins of animals inhabiting Arctic regions, which themselves require protection from the extreme rigour of the climate, are most valuable for the purposes of the furrier. Accordingly the northern parts of Siberia, of European Russia, and of British N. America form the most valuable fur-hunting grounds. The Hudson's Bay Company, which for nearly two centuries possessed a monopoly of the fur trade in the vast tract known as Hudson's Bay Territory, is still the greatest fur-trading body in the world. As the demand for many F. is more regulated by the dictates of fashion than by absolute necessity, prices and values are subject to violent fluctuations. As a rule, the most valuable of all skins for fur is that of the Russian sable, next to which come the finer skins of the black or silver fox of N. America, which sometimes bring as much as £50 each. Of the greatest value, however, in respect of its total annual produce, is the trade in the skin of the northern fur-seal (*Callorhinus ursinus*), which is caught on the small islands off the coast of Alaska. About 130,000 skins are obtained from this source annually, while from various regions in the South Seas about 40,000 skins of the genus *Arctocephalus* are procured. These vary in value according to fashion from about 15s. to 30s. each. While nearly all haired animals may be more or less employed as sources of fur, the following list enumerates the principal varieties embraced in commerce:—Of the family *Canidæ* (dogs) there are the wolf, red fox, Arctic fox, silver fox, and cross fox; of the *Mustelidæ* or weasels, the ermine, the sable, Hudson's Bay sable, the kolinski, the various species of marten, and the sea-otter; of other carnivorous animals, the bears, black, grey, and white, and the various species of seal. Among rodents, the most valuable is the Beaver (q. v.), which, by an ingenious process of removing the long and coarse hairs and dyeing, is made to imitate and rival the fur-seal. There are also the musquash, the chinchilla of the Andes, the grey squirrel, and the rabbit. A vast number of black and grey lambskins, chiefly from Russia, are also used as F. under the trade name of 'Astracans.' The skins of several monkeys are also employed as F., such, for example, as the black monkey of W. Africa and the Abyssinian monkey. The skins of the larger *Carnivora*, the lion, tiger, leopard, &c., are also highly valued as carriage-rugs, &c.

Fürst, Julius, an illustrious Orientalist of Jewish descent, was born at Zerkovo in Posen, Prussia, 12th May 1805. He was educated for a rabbin, and even in his twelfth year showed a marvellously extensive acquaintance with Rabbinical literature. Studies at a German gymnasium and the University of Berlin led him, however, to devote himself to philological science, and he completed (1831) a regular course at Breslau and Halle. His lectures in Leipsic were recognised by the university in 1839, and in 1864 he became a professor. Before his death, 9th February 1873, F. had enriched Semitic learning by innumerable works, of which the best-known is his great concordance, *Concordantiæ Librorum Sacrorum Veteris Testamenti Hebraicæ et Chaldaicæ* (1837-40), and his Hebrew and Chaldee Lexicon (1857-61, 2d ed. 1863, Eng. trans. 1874). Others of great value are *Lehrgebaude der Aramäischen Idiome* (Leips. 1835); *Perlenschnüre Aramäischer Gnomen und Lieder* (Leips. 1836); *Die Israelitische Bibel* (Berl. 1838), translated from the original Hebrew into German; *Der Orient; Berichte, Studien, und Kritiken für Judische Geschichte und Literatur* (Leips. 1840); *Die Jüdischen Religionsphilosophen des Mittelalters* (Leips. 1845); *Geschichte der Juden in Asien* (Leips. 1849); *Bibliotheca Judaica* (1849-53); *Hebräisches und Chaldäisches Handwörterbuch* (Leips. 1857-61, 2d ed. 1863); *Geschichte des Karäerthums* (Leips. 1862-65); and a work on the canon of the Old Testament (the latter published in 1868).—**Livius F.**, son of the preceding, born at Leipsic, 27th May 1840, has acquired some reputation as a poet by his *Märchen von den Sieben Raben* (Leips. 1864), and *Dornroschen* (Leips. 1865).

Für'stenwalde, a walled town of Brandenburg, Prussia, on the Spree, 30 miles E.S.E. of Berlin by railway. Its chief building is a brick church of the 14th c. dedicated to the Virgin, and it has woollen and linen industries, and an active river trade. Pop. (1871) 8197.

Fürth ('the ford'), one of the most important towns of Middle Franconia, Bavaria, on the river Rednitz and the Ludwig's Canal, 5 miles N.W. of Nürnberg by railway. It has a Byzantine town-hall with a tower 180 feet high, a large Roman Catholic church, and several synagogues, while its manufactures are chiefly mirrors, gold and bronze wares, machinery, optical and surgical instruments, paper, colours, &c. A fair, fourteen days in duration, is here held at Michaelmas. The railway between F. and Nürnberg, the first in Germany, was opened in 1865. Pop. (1871) 24,577, of whom 3116 are Jews. Karl the Great founded a chapel at F., and the place came subsequently into the hands of the Burggrafs of Nürnberg. In the Thirty Years' War (1634) the Croats burned F., and in 1680 it was almost completely destroyed by fire.

Fury and Hecla Strait, separating Cockburn Island on the N. from Melville Peninsula on the S., and connecting the Gulf of Boothia on the W. and Fox Channel on the E. It was discovered in 1823 by Parry, but is impracticable for ships. Its western entrance is in lat. 70° N.

Furze (*Ulex*), a genus of Leguminous plants belonging to the subdivision *Papilionaceæ*. The stamens are monadelphous, *i.e.*, united to form a single bundle; the branches spinous, and the leaves reduced to mere thorns in appearance. The calyx is bipartite. The common F. (*Ulex Europæus*) is a very familiar hardy shrub, sometimes growing in immense tracts on bare stony land. The flowers are numerous, solitary, and of yellow colour. F. appears to thrive best in temperate climates, and does not stand winter or severe frosts well. It is used for fodder. In Wales and in Flanders especially F. is highly esteemed for this purpose. Irish F. is the *U. strictus* of botanists, and has very dense branches. *U. nanus* is a very small species or variety.

Fusa'ro, Lago del (anc. *Acherusia Palus*), the supposed harbour of Cumæ (q. v.), in the province of Naples, on the peninsula of Baiæ, 11 miles W. of Naples. It is believed to be the crater of an extinct volcano, having emitted volumes of mephitic gas as late as 1838. In its centre is a pavilion erected by Ferdinand I. At the S. end an outlet of Roman construction

(*Foce de F.*) connects it with the sea, and in the vicinity is the vast ruined villa of Servilius Vatia, with many other relics of antiquity. The lake is still, as in ancient times, famous for its oysters.

Fuse (Fr. *fusée*, originally the *ball* of thread on a spindle, then a piece of artillery of that shape), in artillery, is a case of wood or metal fitted into a shell, and filled with slowly-burning combustible mixture. By a suitable arrangement the F. burns during the time of flight, and then communicates with the explosive mixture in the shell, which is thus calculated to burst as nearly as possible at the moment it touches the earth.

Fuse'li, Henry, a painter, designer, and art critic of great intellectual force but of limited artistic culture, was the son of a Swiss portrait-painter, and was born at Zürich in 1742 Educated for the Church, he entered holy orders in 1761, and soon after removed to London, where for some time he maintained himself by translating from and into the chief Continental languages. Among his works in this kind are a translation into German of Lady M. W. Montagu's Letters, and into English of Winckelmann's *Painting and Sculpture of the Ancients*. At Reynold's suggestion he devoted himself to painting, and removed to Italy in 1770. He returned in 1778, was elected R.A. in 1790, and in 1799 he was appointed Professor of Painting. He died 16th April 1825. F. studied Michael Angelo with great earnestness and much profit; and though his style is low in tone and bad in colour, he did much to emancipate English art from the prevailing mannerisms of the period by vindicating the superiority of design and expression to mere technical dexterity. His *Milton's Gallery*, a series of forty-seven designs from the poet's great epic, is a work of unquestioned genius. See the biographical memoir prefixed to Knowles's edition of his literary works (3 vols. Lond. 1831).

Fu'sel Oil is the name given to the less volatile products separated during the distillation of various alcoholic liquors. It consists chiefly of amyl alcohol ($C_5H_{11}OH$), but it also contains various other alcohols, the propylic, butylic, and hexylic, as well as the ethers of several fatty acids, chiefly those of capric or rutic acid. (See CAPRIC ACID.) Its constituents vary in amount and often in kind with the particular spirit manufactured. Most of the substances present in F. O. act very deleteriously on the system, and this is the reason why inferior spirits are so injurious in their effects, as they are imperfectly rectified. A small quantity of F. O. is present in most spirits, and frequently gives to them their characteristic taste. F. O. is employed officinally in the manufacture of nitrate of amyl. (See AMYL.)

Fusibil'ity, a property of certain kinds of matter, in virtue of which they change their solid for a liquid state under the influence of heat. All solids (except carbon) which do not decompose into their chemical constituents fuse if the temperature be sufficiently great, and the fusion of carbon will probably before long be effected, when our means of applying intense heat are improved. In most treatises on physics, tables are given showing the relative positions of fusible solids as regards their fusing-points. See FREEZING AND FUSING POINTS.

Fu'sible Metal. Many alloys melt at a comparatively low temperature, notably those containing bismuth, tin, lead, and cadmium. Such alloys are termed fusible metals. The following table shows the composition of a few of the more important of these with their fusing-points :—

	Bismuth.	Lead.	Tin.	Cadmium.	Fusing-Point.
Newton's Fusible Metal	8	5	3		94·5
Darcet's ,, ,,	2	1	1		93·0
Darcet's ,, ,,	5	3	2		91·0
Rose's ,, ,,	4·0	·36	207		below 100·0
Wood's ,, ,,	7 8	2	2	1	66–71

Fu'sible Plug, a small plug made of an alloy which melts at a comparatively low temperature. It is placed upon the upper part of the firebox of a boiler, where, if it acts properly, it should melt if the temperature of the water becomes such as corresponds to a dangerous pressure of steam, or if the plate to which it is attached be left uncovered by water. In either case the result ought to be the blowing out of water or steam on to the fire, and the removal in this way in the one case of danger by bursting, and in the other of the risk of overheating the furnace plates. The F. P. is an excellent adjunct to a boiler, but cannot be depended on always to fulfil its intended purpose, so that on no account can it be allowed to supersede a Safety-Valve (q. v.).

Fu'sil (Old Fr. *fusel*, Mod. Fr. *fuseau*, 'a spindle or distaff'), in heraldry, a sub-ordinary, four-sided, presenting two angles perpendicularly and two horizontally. It is more elongated than the lozenge.

Fusil, Fusiliers' (Fr. *fusil*, Ital. *focile;* from Lat. *focus*, 'a fireplace,' in Low Lat. 'a fire'). The fusil was a firelock or light musket, formerly carried by certain British regiments, hence called Fusiliers. The Martini-Henry rifle has been selected for all British infantry regiments, but the name Fusilier is still retained by the following corps—Scots Fusilier Guards, Northumberland F., Royal F., Royal North British F., Royal Welsh F., Royal Irish F., Royal Bengal F., Royal Madras F., Royal Bombay F., and Bengal F.

Fu'sing-Point. See FREEZING AND FUSING POINTS.

Fus't.an (Fr. *futaigne*, formerly *fustaigne;* Ital. *fustagno;* from *Fostat*, a suburb of Cairo, where it was originally made; introduced through Italian commerce with the East), is a thick twilled cotton, of which varieties are velveteen and corduroy. From being an imitation of velvet, its name came to be applied to false, bombastic speech or writing.

Fus'tic. Two kinds of wood, both yielding yellow dyes, are known in commerce under this name, and they are distinguished as old F. and young or Zante F. respectively. The former is the wood of *Maclura tinctoria*, a large tree, native of the W. Indian Islands and S. America. The wood is of a pale-yellow colour, and was formerly much used in dyeing yellow, green, olive, and brown tints. The latter is the wood of a shrub, *Rhus cotinus*, belonging to the S. of Europe. The plant possesses a very peculiar feather-like inflorescence, and yields a fugitive yellow colour, which is only used in conjunction with other dyes to modify their effects.

Fu'sus, a genus of Gasteropodous *Mollusca*, the species of which are often popularly named 'spindle shells' from their shape, and in Scotland 'buckies.' They belong to the whelk family (*Muricidæ*), and have a short spire and a thin outer lip. The siphonal canal is very long. The best-known species is the *F. antiquus*, the 'roaring buckie' of the Scotch, so named from the curious sound resembling the roar of the sea which is heard on placing the shell to the ear. It attains a large size, and is used to form a rude lamp by the Shetlanders, the shell being filled with oil, and the wick drawn through the canal at the mouth. It is also extensively used for bait. *F. colossus*, the giant spindle, is a large species found in tropical seas. Fossil forms begin in the Oolite rocks, and are common in the Chalk, the Lower Greensand, and the Newer Pliocene rocks.

Futak' (Old and New), a village in the county of Bács, Hungary, on the left bank of the Danube, 9 miles W.S.W. of Neusatz. It has a fine castle, has a large trade in tobacco, vegetables, and corn, and a fair, visited by Turks, Armenians, Greeks, &c. Pop. (1869) 4642.

Futtehgunge' (*Fathiganj*, 'market of victory'), the name of two towns in Bareilly district, N.W. Province, British India, 23 miles distant from one another, known as Eastern and Western F. The former was founded by the Nawab of Oude, in commemoration of a victory gained by British troops which gave him Rohilcund, in 1774. The latter is also the site of a victory of the British over the Rohillas in 1796, and the spot is marked by an inscribed obelisk.

Futtehgurh' (*Fathigarh*, 'fort of victory'), a military cantonment on the left bank of the Ganges, 3 miles E. of Furruckabad Town (q. v.) in the N.W. Province. Pop. (1872) 10,335. It is a healthy and favourite station, and its importance has been increased by a branch of the Ganges Canal (q. v.), which here opens into the Ganges. At the mutiny of 1857, the Sepoys turned upon the English residents soon after the outbreak at Cawnpur, and the sufferings of those who escaped were only less dreadful than the fate of the prisoners at the latter place.

Futtehpur' (*Fathipur*, 'town of victory'), the chief town of the district of the same name in the N.W. Province, British India, is a station on the East Indian Railway, 571 miles N.W. of Calcutta, and 267 S.E. of Delhi. Pop. (1872) 20,478. F. has a spacious *sarai*, or lodging-house for travellers, and a small but elegant mosque. At the time of the mutiny of 1857 the English residents escaped with a single exception. The town was shortly afterwards sacked by Havelock, after he had won in the neighbourhood a victory over the troops of Nana Sahib.—*F. District* lies within the Doab, and is bordered both by the Ganges and Jumna. Area, 1586 sq. miles; pop. (1872) 663,877. The land is naturally fertile, and the upper portion is watered by the Ganges Canal (q. v.). The crops are wheat, barley, sugar-cane, indigo, cotton, poppy, and the exports are considerable.

Futtehpur' Sikri, a ruined town of the district of Agra, N.W. Province, British India, 23 miles W. of Agra city. It was the favourite residence of the Emperor Akbar (q. v.), and the ruins, still in a fair state of preservation, attest its former magnificence. The stone wall is 5 miles in circumference. The most striking object within is the mosque, 'which is hardly surpassed by any in India.' This building is 550 feet from E. to W., and 470 feet from N. to S., and contains two tombs of white marble, 'ornamented with pierced tracery of the most exquisite geometrical patterns.' The western gateway is the most celebrated feature, being of such elegant proportions as to be described by Fergusson as 'a romance in stone.' Its greatest height is 120 feet, and it is approached from below by a handsome flight of steps. In less good preservation is the Khas Mehal or palace, about 260 feet square. The Dewani Khas or throne-room contains a throne 'consisting of an enormous flower-like bracket supported on a richly-carved pillar.' Close by are three small pavilions, said to have been erected for three favourite sultanas. See Fergusson's *History of Indian Architecture* (Lond. 1876).

Futtuha' (*Fatwa*, a judicial sentence based on the Koran), a town in the district of Patna, Bengal, British India, at the junction of the Pûnpûn with the Ganges, and a station on the East Indian Railway, 390 miles N.W. of Calcutta, and 10 E. of Patna. Pop. (1872) 11,295. It is the seat of some trade, as well as the resort of multitudes of pilgrims, who flock hither at certain seasons to bathe in the Ganges.

Fu'ture Debt. In England, under common law, no procedure can under any circumstances be taken on a debt before the date on which it falls due. This legal doctrine formerly gave rise in bankruptcies to hardships and injustice, to obviate which various statutory provisions have been made. Under these, postponed or contingent debt can now be reduced to its immediate value, and procedure follow accordingly. In Scotland the doctrine of Roman law regarding F. D. has always been held—that in the event of the death or bankruptcy of the debtor, the creditor is entitled, by deducting a proper discount, to make his claim immediate. The Scotch law also gives to the future creditor the privilege of Arrestment (q. v.) in security. The contingent creditor in a Scotch sequestration may have his debt valued, and may vote and draw dividend accordingly.

Fyne, Loch, an inlet of the Firth of Clyde in the S of Argyleshire, noted for its herring-fishing, is 43 miles long, 2 to 10 broad, and has a depth of from 40 to 70 fathoms. It begins in the N.E. of Cantire, has a N. and N.E. direction, separating first Cowal on the E. from Knapdale on the W., then Cowal from the Inverary and Loch Awe districts, and sends off to the W. Loch Gilp, which is linked by the Crinan Canal to the Sound of the Jura. The hilly shores are steep and bare, but round Inverary, near the top of the loch, there is finely-wooded scenery.

Fyzabad' (*Faizabad*, 'town of plenty'), the chief town of the district of the same name in the province of Oudh on the right bank of the Gogra, 89 miles E. of Lucknow. It is a station on the Oudh and Rohilcund Railway. Pop. (1869) 37,804. F. town, a modern suburb of the ruined city of Avadha or Oude, was founded about 1730 by the first Nawab of Oude; but the seat of government was removed to Lucknow in 1775, and since then the importance of F. has decreased. It was the residence of the Begums of Oude, whose title is known in connection with Warren Hastings. The Gogra is here navigable for large boats, which carry a considerable export trade in rice, wheats, and other cereals, oilseeds and sugar. The manufactures are native cloth, metal vessels, and firearms.—*F. district* contains an area of 2332 sq. miles; pop. (1869) 1,437,009.

G.

the seventh letter in the English alphabet, occupying the same position in the Latin. In the Greek, as in the original Phœnician alphabet, it came third, and the names *gamma* and *gimel*, which it respectively bore in these tongues, show that in origin it was identical, both in sound and in shape, with its cognate *c*. In Latin the name Caius was long written as Gaius, and G always retained its proper phonetic value as a hard guttural, as it still does in German. The softened sound of G, which is closely analogous to the softened sound of *c*, came in when the Romance languages took shape, and was thence introduced into English. It is now always hard before *a*, *o*, and *u*, and usually soft before *e*, *i*, and *y*. In Italian, by means of the compound letter *gh*, the rules for pronunciation are more precise. In the same language before *l* it loses its own sound, and changes the sound of that letter to *ly*. It has a tendency to become altogether mute before *n* and *h*, and even to be dropped from the written tongue, as Latin *natus ognatus*. During the last century it was fashionable to insert *y* in the pronunciation of G when this letter commenced a word, as garden = *gyarden*. This shows the close affinity between these two letters, which may also be exemplified by the participial prefix *ge-* in Old English becoming in Transition English *y*, as *y-clept*. G also interchanges with its cognates *c* and *k* and *ch*. Lat. *gnosco* is Eng. 'know;' Eng. 'eight' is Lat. *octo*, Greek *okto*, Ger. *acht*. As an abbreviation G. stands for Grand, as G.C.B. = (Knight) Grand Cross of the Bath.

G, in music, the tone which is a perfect fifth above or fourth below C. The particular G whose vibration number is 396 is represented by the second line of the treble stave.

Gaal, Jozsef, a Hungarian writer of considerable reputation, was born at Gross-Karoly in 1811. Educated at the University of Pesth, he has devoted himself chiefly to politics and literature, particularly humorous poetry, comedies, and sketches of Hungarian life. On the occasion of the rising of the Hungarians against Austria he was appointed Finance Minister to the Provisional Government. Among his works are *Szyrmay Ilona*, a novel in 2 vols. (Pesth, 1836); *Király Ludnem* (Pesth, 1837); *Vdeskei Notarius* (Pesth, 1838), one of the best specimens of Hungarian comedy; and *Szerelem és Champagnir* (Pesth, 1840).

Gabb'ion, or **Gab'ion** (Fr.; Span. *gavion*, Ital. *gabbione*, 'a large cage;' connected with Lat. *cavea*, 'a hollow'), a cylinder of wickerwork, or basket without lid or bottom, usually 3 feet in height. It is made by drawing a circle on the ground about 22 inches in diameter, driving from eight to twelve pickets, ⅝ths to ⅞ths of an inch in diameter, and pointed at both ends, into the earth at regular intervals on the circle described, and then constructing a web of basketwork upon the pickets with wattles or thin pliant rods. Gabbions filled with earth and ranged in one or more rows, form a useful and eminently manageable means of defence against musketry and even small field-guns. Disposed in alternate rows with fascines, they make a good revetment or lining of the escarp. Placed on the summit of the parapet, with narrow intervals between each for firing through, they afford valuable cover for the defenders of field fortifications. *Gabbionades* are lines of gabbions thrown up for cover.

Gabb'ro, the name given by Italian geologists to Diallage (q. v.).

Gabelentz', Hans Conon von der, a German philologist, born at Altenburg, October 13, 1807, and studied at Leipsic and Göttingen. He entered on a successful political career and in 1851 became President of the Altenburg Diet. He has throughout his life been devoted to philology, and has greatly advanced the study of various Turanian and other dialects. He was one of the founders of the *Zeitschrift für die Kunde des Morgenlandes* (1837, *et seq.*), in the second volume of which appeared his *Grammatik der Mordwinischen Sprache*. Other valuable works of G.'s are his *Grundzüge der Syrjänischen Grammatik* (Altenb. 1841); his critical edition of Ulfilas, with a Latin translation, glossary, and Gothic grammar (2 vols. Leips. 1843-46); *Beiträge zur Sprachenkunde* (Leips. 1852); *Ueber die Melanesischen Sprachen* (1860); *Ueber das Passivum* (1860); and (1864) Manchurian translations of the Chinese works *Se-Shu*, *Shu-King*, and *Shi-King*, with a glossary.

Gabelle', a French word denoting a tax on salt. In English law it may be applied to any other tax, or to rent, custom, or service. The word is of Teutonic origin. In Old Eng. it appears as *gafol*, 'tribute,' from the verb, *gifan*, 'to give.'

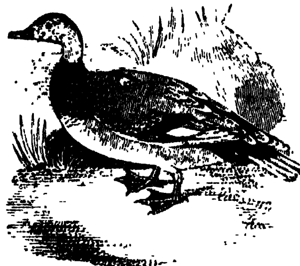
Ga'ble (Goth. *gibla*, 'a pinnacle') is the property of the party who builds it, even though partly resting on the ground of another, and the builder may prevent the owner of the other ground from using the G. until he has paid half the expense of building it.

Gaboon', a river of W. Africa, rises in the Crystal Mountains, and after a sinuous course of 120 miles, enters the Atlantic near the equator by a wide estuary. Much ivory is procured in the basin of the G., which is occupied by many native tribes. The climate is unhealthy. The French planted a colony at the mouth of the river in 1845, which was broken up in 1871, but has since been re-established.

Ga'briel (Heb. 'man of God,' a generic title of an angel), in the Jewish traditions was one of the seven Archangels (q. v.). In the Hebrew Scriptures, as with the ancient Persians, he appears as *the angel of revelations*. Thus he appeared to Daniel to make him understand his vision (viii. 16), and after his prayer to give him 'skill and understanding' (ix. 21-22). In the same character he appears to Zacharias and to Mary (Luke i. 19, 26-27). Hence Mohammed feigned that he received from G. the Koran (in which he is called the Holy Spirit and the Spirit of Truth) and instructions about a number of his actions. See Sale's *Koran*.

Gachard, Louis Prosper, an eminent archivist, born at Paris in 1801. He was at first a working printer, but devoted himself to history, and removed to Belgium, of which country he was made archivist in 1831. G. has thrown much fresh light on Belgian history, and especially the Spanish occupation of the Low Countries. Among his works are *Analectes Belgiques* (1830); *Documents Inédits* (1845); *Relations des Troubles de Gand sous Charles-Quint* (1846); *Correspondance de Guillaume le Taciturne* (5 vols. Bruss. 1847-65); *Correspondance de Philippe II. sur les Affaires des Pays-Bas* (3 vols. Bruss. 1848-59); *Don Carlos et Philippe II.* (Bruss. 1863); *Actes des États Généraux des Pays-Bas* 1576 *à* 1585 (1866), &c.

Gad was the seventh son of Jacob, by Zilpah, Leah's maid. The derivation of the name given in the A. V. (Gen. xxx. 11), which follows the Masoretic text, is very obscure. The best critics consider the original text would mean—'Leah said, *To my good fortune*' (*sc.* a son is born); 'and she called his name *Good Fortune*.' This would correspond with Isa. lxv. 11, where 'that troop' of the A. V. is understood by some to refer to the god or goddess of fortune under the form of the planet Jupiter or Venus respectively. The tribe of G., which numbered in the



first census (Num. i.) 45,650 fighting men, in the second (xxvi.) 40,500, settled along with the tribe of Reuben and half tribe of Manasseh on the E. of Jordan (Num. xxxii.). See Delitzsch's *Commentary on the Pent.* (Clark's trans. 1867), and *Isaiah* (1869).

Gadames, or **Ghadames** (Lat. *Cydamus*), an oasis and town of Africa, in the S.W. of Tripoli, and on the border of the Sahara. It is a place of some traffic, lying on the routes between Tripoli, Tunis, Ghat, Tidikelt, &c. The tolls and land tributes amount to £1700 yearly. There are springs of 89° F., watering the gardens, which yield dates, wheat, millet, &c. The town has six mosques and seven schools, where the Koran is taught, along with a little Arabic writing. Pop. 5000.

Gadfly. See BOT and TABANUS.

Gadidæ, an important family of Teleostean fishes belonging to the section *Malacopterygii*, or 'soft-finned' fishes, and distinguished by having a long scaly body and a symmetrical head. The ventral fins are jugular in position, that is, are placed on the throat below the pectorals. To this family belong the cod, whiting, haddock, Dorse (q. v.), &c

Gad'wall (*Chaulelasmus strepera*), a species of *Anatidæ*, or Ducks (q. v.), common in N. America, in some parts of the continent of Europe and Asia, and occasionally found in the British Islands. It is imported from Holland in large quantities for the London market. The plumage is of sober colour, and the voice harsh and noisy. The nests are usually found in marshy ground, and from seven to nine eggs are generally laid.

Gadwall.

Gæ'a, or **Ge**, the Greek goddess of the earth, and, according to Hesiod, the first-born of Chaos and mother of Uranus. G. is one of the strange, gloomy Chthonian deities who seem to have belonged to an earlier, ruder religion than that of classic Greece. They are closely connected with the earth, and contrast strongly with the bright Olympian divinities who are native to the sky. G. corresponds to the Latin earth-goddess *Tellus*.

Gaelic Language and Literature. The Gaelic, as distinct from the Cymric family of the Celtic language, comprises three dialects, viz., Irish, Scottish, and Manx Gaelic, all of which show closer kinship with the Latin than with any other Aryan tongue.

The Book of the Dean of Lismore proves that 300 years ago Scotland possessed a native common, or Bardic, dialect widely differing from the foreign (Irish) and ecclesiastic. In the present day we find such differences still in existence—*e.g.*, the Irish use both the analytic and synthetic forms of the verb, the Scottish only the first. The Irish gives a present tense to the verb, the Scottish none. In Irish, nouns never take *n* in the plural, in Scottish they often do. In Irish what is called *eclipsis* is used to an extent altogether unknown in Scottish. In Irish the negative is *ni*, in Scottish *cha;* and in pronunciation, in idiom, and in vocables wide differences between the two are met with.

The lectures of Professor O'Curry on the 'MS. materials of Irish History' (Dublin, 1861) prove that many thousands of pages, written from the 10th to the 15th centuries, and embodying much written at an earlier period, are still to be found in public libraries and private collections throughout the kingdom, dealing with a great variety of subjects, and written often with great ability. Several volumes of the ancient laws and the historical annals of Ireland have been published at the national expense. The oldest Scottish Gaelic, strictly so called, which has been preserved is in the Dean of Lismore's Book, written from 1512 to 1540, a commonplace-book mainly filled with Gaelic heroic ballads, several of which are ascribed to the authorship of Ossian or his kindred. It proves that Ossianic heroic poetry was known and esteemed in the W. Highlands 300 years ago, and its peculiar orthography demonstrates, as already said, the existence of a separate Scottish Gaelic dialect. *Leabhar na Féinne* ('the Book of the Fingalians'), published by Mr. Campbell (Lond. 1872), contains the heroic ballads of the Dean's Book, placed side by side with all the other versions of them that have been gathered since, also a few not found in the Dean's collection, and is a work of immense labour. The poems of Ossian published by MacPherson (English translation 1762-63, Gaelic originals 1807) are undoubtedly Gaelic, whatever opinion be formed of their age or authorship, and in the opinion of scholars are unrivalled for sublimity and pathos by any other production of the Celtic muse. The fullest edition is that by Dr. Clerk (Edinb. 1870). 'The ancient poems,' *Sean Dàna*, published by Dr. Smith (1782), also deserve the highest praise. Of modern poets we may note a few of the best. Mary Macleod of Skye, born 1569, is an authoress full of Pindaric fire and freedom. John Lom or MacDonald, who was at the battle of Inverlochy (1645), is fully more of a politician than a poet, but he is a great favourite with his countrymen. Alasdair MacDonald of Ardnamurchan, 'the Tyrtæus of the '45,' was a classical scholar, and his *Birlinn* is probably the ablest modern poem in the language, but many of his pieces are disfigured by a pedantic display of learning, and an intolerable accumulation of synonymous epithets. Duncan Bàn MacIntyre, his contemporary, is beyond all question the 'Burns' of the Highlands. Rob Donn (q. v.) is a bard whose fame surpasses his merit. The names of John MacCodrum and William Ross are familiar to Gaelic ears. Buchanan and MacGregor have written religious poems of great merit, and there are crowds of lesser lyrists whose praise of love or war still kindles enthusiasm in Celtic breasts.

Mr. Campbell, already mentioned, published in 1866 a large collection of W. Highland tales in prose, but the only Gaelic prose worthy of the name was either edited or composed by the late Dr. Norman Macleod of St. Columba, Glasgow, in his periodicals. A collection of his own works—*Caraid nan Gàel*—edited by Dr. Clerk (Glasg. 1867) shows more of the flexibility and gracefulness of the language than any extant composition.

The first book ever printed in G. was a translation of Knox's Liturgy by Bishop Carsewell of Argyle in 1659. The Synod of Argyle in the same year published a translation of the first fifty Psalms and of the Shorter Catechism. The first Gaelic Bible was published in 1786. There are two good grammars of the language, Dr. Stewart's and Munro's; a good dictionary by Armstrong, a larger one by the Highland Society, and smaller ones by Dr. Macleod and Mr. Macalpine. Professor Blackie, who has successfully laboured to collect funds for the endowment of a Celtic Chair in Edinburgh, has written a very interesting and instructive work on the *Language and Literature of the Scottish Highlands* (1876), which may be recommended to English readers.

The Gaelic is rich in terms descriptive of *external* nature, and of the emotions of the mind, but entirely destitute of those relating to metaphysics and natural science. Notwithstanding the general impression of its ruggedness, it is in pronunciation soft and vocalic, like the French in its nasal tones, and also in loss of original vigour through the too frequent suppression of consonantal sounds both medial and terminal.

Gäeta (the ancient *Caieta*, perhaps from the Gr. *kaietas*, 'a hollow,' on account of its caves), an Italian town in the province of Caserta, 40 miles N.W. of Naples. It is situated on a high steep promontory, jutting into the beautiful Bay of G., is sheltered by wooded hills, and has some fisheries, and a coasting trade in wine, oil, fruits, &c. In its citadel, one of the strongest in Italy, is the tomb of Constable Bourbon, who sacked Rome in 1527. It possesses several ancient remains, of which the most interesting is the sepulchre of Munatius Plancus, a circular building, now known as the Torre di Orlando, which stands on the summit of the headland. G. was a busy port in the time of Cicero, and a favourite resort of the Roman nobility, who had many splendid villas along its shore. It was the first Italian town which became a commonwealth during the middle ages, and has sustained various sieges. After holding out bravely during three months for the King of Naples, it surrendered to Cialdini in 1861. Pop. 10,000.

Gætu'lia, the ancient name of a wild country in the N.W. of Libya, embracing the S. region of Morocco, and the W. part

of the Great Desert. It extended from the Atlantic eastward to the region of the Garamantes, and was bounded on the S. by the river Niger. The Gætulians belonged to the great Berber (q. v.) stock. Those of the N. were of a yellowish-brown complexion, dark-haired and dark-eyed; while their southern neighbours, from mixing with the Negroes, were nearly black in colour, and were called *Melanogætuli* ('black Gætulians'). They were unsettled, warlike, savage, and implacable. They first appear in history as cavalry in the army of Jugurtha. In A.D. 6 they were defeated by Cornelius Cossus Lentulus, who, for his success, received the surname Gætulicus and the *ornamenta triumphalia*. The Berbers of Mount Atlas, and the Tuaricks of the desert, are thought to be the descendants of the ancient Gætulians.

Gaff (Dan. *gaffel*, Welsh *gaft*, 'a fork'), in a ship or sailing boat, is the spar to which the upper edge of a fore-and-aft sail is bent, the lower edge, except in a sprit-sail, being attached to a boom. The G. is probably so named from the fork-like appearance of the 'jaws,' with which it slides up or down the mast.

Gage. See GAUGE.

Gage, Thomas, governor of Massachusetts, was born in England in the early part of the 18th c. Having fought in the Seven Years' War, he was made governor of Montreal in 1760, obtained the chief command of the British forces in America in 1763, and finally arrived in Boston in May 1774 as governor of Massachusetts, when the dispute between the colonists and the mother country was assuming formidable dimensions. He excited odium by his policy and procedure, such as fortifying Boston, planning the expedition to Concord which ended in the battle of Lexington (April 19, 1775), and proclaiming martial law in Massachusetts. He was declared an enemy to America by the Congress then assembled. After the battle of Bunker's Hill, June 17, 1775, G., being superseded by General Howe, sailed for England. He died April 1787.

Gagea, a genus of Monocotyledonous plants belonging to the natural order *Liliaceæ*. It embraces numerous species found chiefly in Europe and the cooler parts of Asia and Africa. *G. lutea* is the only one indigenous to Britain.

Gag'ern, Hans Christoph Ernst, Freiherr von, a German writer and statesman, born at Klein-niederheim, near Worms, January 25, 1766, became Chief Minister to the House of Nassau in 1814, represented the Low Countries at the Vienna Congress, opposed the scheme of German federation, and died at Hornau, October 22, 1852. Among his works are *Die Fürsten* (Frankf. 1808); *Aristokratie* (Vienna, 1812); *Demokratie* (Frankf. 1816); *Politik* (Stuttg. 1818); *Die Nationalgeschichte der Deutschen* (2d ed. Frankf. 1825-26); his Memoirs, under the title *Mein Antheil an der Politik* (5 vols. Stuttg. and Leips. 1823-44); *Civilisation* (1847), &c.—**Friedrich Baldwin G.**, son of the above, born at Weilburg, October 24, 1794, joined the Austrian army, fought at Dresden, Kulm, Leipsic, &c., became a general, afterwards entered the Dutch service, and was killed at Kardern, April 20, 1848.—**Heinrich Wilhelm August, Freiherr von G.**, brother of the preceding, was born at Baireuth, August 20, 1799, entered the service of Nassau, and fought at Waterloo. He afterwards studied at Göttingen, Jena, and Heidelberg, and was one of the founders of the *Burschenschaft*. He then passed to the administrative service of the Duke of Hessen-Darmstadt, and became private secretary to the Minister of the Interior, a post which he had to give up on account of his Liberalism. In 1847 he was re-elected to the Darmstadt Diet, and in 1848 made Prime Minister. In 1852 he retired from public life. His favourite political project was to unite Germany into a confederacy of small free states, and to form a close alliance between them and Austria. His career has been marked by patriotism and moderation. From 1864 to 1870 G. was ambassador for Hessen Darmstadt at the court of Vienna. He has written a life of his brother, *Das Leben des General Friedrich von G.* (3 vols. Heidelb. and Leips. 1856-57).

Gaill'ac, a town in the department of Tarn, France, on the river Tarn, 32 miles N.E. of Toulouse by railway. It lies in a rich wine district, and has some distilling, tanning, turnery, and dyeing. Its chief building is an abbey church of St. Michel of the 13th c. Pop. (1872) 5694. G. grew up about a Benedictine abbey founded by Raymond I., Comte de Toulouse, in the 10th c.

Gaill'ard, Gabriel Henri, a voluminous French author, was born at Ostel in 1726. He was educated for the bar, but chose a literary life, and cultivated history and rhetorical composition with much temporary success. He was during forty years the friend of Malesherbes. He finally retired to Saint-Firmir, near Chantilly, where he died, February 13, 1806. His works include *Histoire de la Rivalité de la France et de l'Angleterre* (1771-77); *Histoire de Charlemagne* (1782); *Histoire de la Rivalité de la France et de l'Espagne* (1801); *Essai de Rhétorique Française* (1745); *Éloge de René Descartes* (1765); *Epître aux Malheureux* (1766), &c.

Gai'mar, Geoffrey or **Geffrei**, a Norman-French *trouvère* who flourished in the middle of the 12th c. He lived in the household of Ralph Fitz-Gilbert, a baron of the N. of England, and translated Geoffrey of Monmouth's Latin chronicle into French verse, enlarging it with a series of tales of early English kings. His version known as *L'Estorie des Engles* was soon superseded by Wace's more popular rendering.

Gains'borough ('the town of the Ganii'), a seaport of England, in Lincolnshire, on the Trent, 20 miles above its mouth in the Humber, and 16 miles N.W. of Lincoln by railway. It consists chiefly of one long street parallel to the river, which is crossed by a stone bridge of three elliptical arches, erected in 1791. There is a curious old 'manor house,' partly tenanted by private families, which is said to have been the residence of the ancient lords of the manor. G. has also a grammar-school of date 1589, and an old church, rebuilt in 1736, with a tower of the 12th c. The harbour can be approached by vessels drawing 12 feet of water, has large manufactures of linseed oil, malt, and cordage, and does an active transit trade between the interior and the North Sea. Pop. (1871) 7564.

Gainsborough, Thomas, R.A., one of the greatest of English painters, was born at Sudbury, Suffolk, in 1727. His father was poor, and he received little education, passing his days mainly in sketching, until in his fifteenth year he went to London, where he studied painting for four years, and then resided for twelve years in Ipswich. In 1760 he settled in Bath, and worked there very successfully as a portrait-painter until 1774, when he returned to London, whither his fame had already spread. Henceforth his career was one of brilliant success. He was one of the thirty-six original members of the Royal Academy, and contributed regularly to its exhibitions. He died in London, August 2, 1788. Among G.'s best-known works are 'Hon. Mrs. Graham,' 'Shepherd Boy in the Shower,' 'The Seashore,' 'Cottage Girl with Dog and Pitcher,' 'Shepherd Boys with their Dogs Fighting,' and the 'Blue Boy,' painted to disprove the statement of Reynolds that blue should be excluded from masses of light. Uninfluenced by the foreign masters, G. developed a style 'pure in its English feeling, profound in its seriousness, graceful in its gaiety.' Ruskin says, 'G. is the greatest colourist since Rubens, and the last, I think, of the legitimate colourists.' His execution, however, is slightly mannered and always hasty, and his works are altogether lacking in 'affectionate details.' G. usually worked with cooler tints than Reynolds, and delighted in an enchanting play of blue and silver. In the treatment of a subject he combined audacity and finesse, and often produced most delicate effects by summary methods. His landscapes have idyllic feeling, and his portraits are marked by bewitching vivacity. See Fulcher's *Life of G.* (1856), and Wedmore's *Studies in English Art* (Lond. 1876).

Gai'us, a celebrated Roman jurist, flourished between 110 and 180 A.D. Of his personal history little is known. It is even uncertain whether his name should be written Gaius or Caius, and indeed whether it is a nomen or prænomen. By some he is considered a Greek, by others an Illyrian. Some learned civilians have erroneously thought him a Christian. G. is best known by his *Institutes*, which were compiled, or at all events completed, in the reign of M. Aurelius, and formed the basis of the more celebrated *Institutes* of Justinian. Before the reforms made by Justinian in the legal curriculum for students, this work and four other treatises by G. were honoured as textbooks in the schools of law. The *Institutes* were lost till a palimpsest containing the MS. of the work of G. under that of the *Letters* of St. Jerome, was discovered at Verona by Niebuhr in 1816. The difficult task of deciphering the original MS. was successfully accomplished by two German scholars, Göschen and

Hollweg, and the result of their labours was published by the former in 1821. A second edition was issued in 1825, a third by Böcking in 1837, a fourth by Lachmann in 1842, and a fifth by Huschke in 1861. G. was the author of numerous other works. The chief are *Edictum Provinciale, Edictum Urbicum, Aureon, De Verborum Obligationibus, De Manumissionibus*, and *De Casibus*. In the *Digest* there are no fewer than 535 extracts from his works. See Huschke, *Zur Kritik und Interpretation von Gaius Institutionen*, in his *Studien des Römischen Rechts* (Breslau, 1830); Krüger, *Kritische Versuche im Gebiete des Römischen Rechts* (Berl. 1870); Teuffel, *Geschichte der Römischen Literatur*, sec. 357 (Leips. 1872).

Galac'tic Cir'cle (Gr. 'milky circle'), the name given by Sir John Herschel to the great circle in the heavens which most nearly corresponds to the position of the Milky Way (q. v.).

Galactoden'dron (Gr. 'milk-tree'), the generic name of the Cow-Tree (q. v.) of S. America.

Galactom'eter, or Lactom'eter (Gr. 'milk-measurer'), a form of apparatus for approximately testing the richness of milk by observing the amount of cream which rises from a given quantity. The apparatus is simply a graduated test-tube. The specific-gravity G. which is sometimes used is very delusive, seeing that milk deprived of cream is of higher gravity than pure new milk.

Galacz', the great river-port of Rumania, in Moldavia, between the left bank of the Danube and the Karamon or Bratych Lake, 15 miles above the confluence of the Danube and Pruth and N.E. of Bukarest by railway. It is one of the chief harbours on the Danube, has regular steam communication with Vienna, Constantinople, and Odessa, and is a free port for goods that are to be consumed in the town. The new portion of the town is built on an elevation, and includes most of the public buildings. G. has a good quarantine-hospital, large magazines and stores, extensive quays, &c. The trading people are chiefly Greeks, to whom belongs over half the home shipping. The Danube is frozen usually from the 16th December to the beginning of February. In 1874 there cleared the port 367 steamships of 218,603 tons, and 1072 sailing vessels of 146,922, 166 of the former being British, 466 of the latter belonging to Greece. The exports, chiefly wheat, barley, maize, flour, deal planks, oats, rye, colza, petroleum, and hides, amounted in value (1874) to £1,660,401; the imports, valued at £1,778,426, include cotton and woollen goods, building-stones, iron, coal, caviare, watches, jewellery, coffee, sugar, tea, tobacco, &c. G. is a station on the railway which, after traversing Moldavia, enters Austrian Galicia, and is merged in the systems of Central Europe. By a law (1874) of the Rumanian Government, G. will cease to be a free port on the 1st of January 1878. Pop. 80,000.

Gala'go, a genus of *Lemuridæ* or Lemurs (q. v.) having large naked ears and large eyes. The tarsus is elongated, and the tail long and thickly furred. The little G. (*G. minor*), and the Moholi G. (*G. Moholi*), are familiar species, inhabiting Madagascar and the adjoining African coast. The former, known as the 'Madagascar rat,' has a light-brown fur, and attains a length of about a foot; the latter is of grey colour, marked with darker tints, and attains a length of 16 inches. These animals are nocturnal in habits, and feed on insects, fruits, and small birds.

Galan'gal, or Galan'gale, the name applied to species of *Alpinia* belonging to the Ginger order. They are very aromatic, and are sometimes used in the East as ginger. From the rhizome of *A. Galanga*, a native of the Eastern Archipelago, an arrowroot is prepared. *A. alba* yields the fruits known as China cardamoms.

Galan'thus, the generic name of the Snowdrop (q. v.).

Galapa'gos (Span. *galapago*, 'a tortoise'), a group of six large and seven small islands in the Pacific, 200 miles off the Peruvian coast, near the equator, and in long. 89–92° W. They are volcanic in origin, and are almost solely tenanted by turtles and aquatic birds. The largest, Albemarle (60 miles long, 15 broad), reaches a height of 4000 feet.

Galashiels' ('the shielings or huts on the Gala'), a manufacturing town of Scotland, partly in Roxburgh, partly in Selkirk, on the Gala Water, just above its confluence with the Tweed, 4 miles N. of Melrose, and 33½ S. of Edinburgh. It is a railway junction, and the chief seat of the Scotch tweed manufacture, having (1876) 20 woollen factories, with 100 'sets' of carding-engines, using 220,000 stones of wool, and producing goods to the value of £750,000 yearly. There is here also a skinnery capable of preparing 35,000 skins weekly. The town, which is irregularly built in the confined valley of the Gala, was made a burgh of barony in 1630, and with Hawick and Selkirk sends one member to Parliament. Pop. (1871) 9678. Power was granted to extend the burgh and introduce a water supply by Act of 1875.

Gal'ata, a suburb of Constantinople, on the opposite side of the Golden Horn from the city proper, with which it is connected by two bridges. It is the business quarter, and is populous and filthy.

Gala'tia, or Gallogræ'cia, the ancient name of a beautiful and fertile country in the centre of Asia Minor. It was so called from the Gauls who migrated thither in the 3d c. B.C. These Gauls formed part of the immense hordes which under Brennus invaded Greece, and afterwards carried their arms across the Hellespont. In 239 B.C. they received a check from Attalus, King of Pergamus, and in 230 B.C. were constrained to settle down in a part of Phrygia, thenceforward called G. They adopted Greek customs, but for centuries retained their own language. They had a federal government, and were under their own chiefs till 36 B.C., when Amyntas, one of the tributary Asiatic kings set up by M. Antony in 39 B.C., received G., in the possession of which he was confirmed by Augustus, 31 B.C. G. became a Roman province in 25 B.C. Its chief towns were Pessinus, the seat of the worship of Cybele; Ancyra, the capital of the province under the Romans; and Gordium, where Alexander cut the Gordian Knot (q. v.).

Gala'tians, Epistle to the, was written by St. Paul not long after his journey through Galatia and Phrygia mentioned in Acts xviii. 23. This was his third missionary journey and his second visit to Galatia (about 55 A.D.). The word *strengthening*, or confirming, implies that the inhabitants had already been converted. The Galatian churches must therefore have been founded at a previous visit—that is, on the apostle's second missionary journey (Acts xvi.), or about 52. The question is how long after 55 the date is to be placed. Owing to the similarity between the epistle and those to the Corinthians and the Romans, the most likely position for it is considered to be after the former and before the latter; in other words, it was most probably written towards the close of his two to three years' sojourn at Ephesus (Acts xix. 55–57), or soon after he went to Corinth (57–58). The object of the epistle was to counteract the influence and refute the statements of certain Judaising teachers who had come after the apostle in Galatia, and who were seeking to undermine his teaching by contemning his apostolic authority (i. ii.), and by teaching directly that circumcision was necessary (iii.–v. 12). See Davidson's *Introd. to the New Test.* (new ed. 1868); Lightfoot's *Ep. to the G.* (2d ed. 1866).

Galati'na, a town in the S. of Italy, province of Lecce, 12 miles N.W. of Otranto. It has several fine churches, among others that of Santa Caterina, founded by a prince of Taranto, who is said also to have surrounded G. with walls in gratitude to its citizens for ransoming him from the Turks. Pop. 10,334.

Gala Water, a small Scottish river, which rises in the Moorfoot Hills, in Edinburghshire, flows through Selkirkshire, which it separates in part of its course from Roxburghshire, and after receiving the Heriot and other hill-streams, joins the Tweed near Abbotsford. It is 21 miles in length, and flows through romantic scenery famous in Scottish ballads. The G. is well known from one of Burns's songs.

Gal'axy, The (Gr. *gala, galaktos*, 'milk'), the name sometimes given to the Milky Way (q. v.).

Gal'ba, Ser'vius Sulpi'cius, Roman emperor from June 68 to 15th January 69 A.D., was the son of C. Sulpicius G. and Mummia Achaica. He was born 24th December 3 B.C. As a young man he evinced great ability, and attained the curule offices before the usual age. He received the province of Aquitania in 20 A.D., was consul in 33, and conducted the administration of Gaul in 39, and of Africa in 45 and 46 with equity,

moderation, and diligence. In 61 Nero gave him the province of Hispania Tarraconensis, where he remained eight years. In 68, instigated by Julius Vindex, who had risen with the Gallic legions, and hearing that Nero plotted his death, he resolved to place himself on the throne. Meanwhile Nero was murdered, and G. assumed the title of Cæsar. Once emperor, he became the creature of his favourites. This, added to the character he bore for niggardliness and avarice, caused disaffection among the legions in Germany, and he was assassinated one day as he was being carried through the Forum in a litter.

Gal'banum, a gum resin obtained from an umbelliferous plant, is imported from India and the Levant in masses of greenish-yellow or reddish translucent tears. Its medicinal properties are similar to those of assafœtida, but less powerful. G. is used, *internally*, as a stimulating expectorant in chronic affections of the bronchial mucous membranes; and, *externally*, as a plaster to promote resolution or suppuration of indolent swellings. The preparations are *emplastrum galbani*, and *pilula galbani*, now known as *pilula assafœtidæ composita*. It is not definitely known from what plant the gum is derived.

Gale, Sweet Gale, or **Bog Myrtle**, popular names applied to the British shrub *Myrica G.*, the badge of the Clan Campbell. It is found most abundant in Scotland in bogs and moory ground, from the coast-line to about 1400 feet. Its leaves diffuse a very agreeable odour; they are bitter in taste, and have sometimes been used as hops. In the Western Highlands the inhabitants scent their clothes with the foliage, and in some parts of Scotland beds are made of the twigs. The Candleberry Myrtle (q. v.) of N. America is an allied species.

Ga'len, Christoph Bernhard von, a German prelate and general, was born at Bispink in Westphalia, October 15, 1600. After completing his studies he entered the military service of Ferdinand of Köln, on whose death he laid aside arms, took holy orders, and in 1650 became Bishop of Munster. The inhabitants, discontented with the rigid discipline which he enforced, applied to Holland in 1657 for aid against him; but G. quelled the insurrection by force of arms, and in 1661 built a citadel to keep the town in submission. As one of the directors of the *Rhein-Bund*, he proceeded with his own troops as far as Hungary to fight against the Turk, and materially assisted in the victory of St. Gothard. Engaged for a brief time in 1665 as England's ally against Holland, he united with France in 1672 against the same country, but having suffered great loss in 1674 through the flooding of his camp during the siege of Coevorden, concluded a treaty promising to restore his conquests. In the succeeding year he aided Christian V. of Denmark and the Elector of Brandenburg against Karl XI. of Sweden, and added the duchy of Bremen to his possessions. In 1678 he became involved in a war with Friesland, but died 19th September in the same year.

Gale'na, or native sulphide of lead, crystallises in the cubic system, is generally lead-grey in colour, with a shining metallic lustre. When pure it is composed of 86·55 lead and 13·45 sulphur, but frequently contains sulphide of silver and sometimes sulphide of zinc. It occurs in veins in granites, limestones, sandstones, gneiss, &c., often associated with zinc, silver and copper ores, and generally with quartz, heavy spar, sometimes fluor spar, as gangue. It occurs abundantly in the N. of England, in Saxony, Bohemia, and United States, and is widely wrought as the chief source of lead. Considerable quantities of silver are obtained from *argentiferous G.*

Gale'na, a city, Illinois, U.S., on the Fevre river, 5 miles from the E. bank of the Mississippi and 180 miles W.N.W. of Chicago. It is picturesquely built on bold bluffs, some of the streets being in terraces connected by flights of steps. G. derives its name and existence from the extensive lead-sulphide mines in the vicinity. It has also a trade in pork-packing, lumber, furniture, and pottery, with breweries, foundries, and flour-mills. Pop. (1870) 7019.

Gale'nus, Clau'dius, commonly called **Ga'len**, a famous physician, born at Pergamus, 130 A.D. His father, Nicon, was an architect and geometrician. After studying medicine in his native city, G. travelled extensively, prosecuting his studies under distinguished teachers at Smyrna, Corinth, and Alexandria. In 158 A.D. he returned to Pergamus, where he was appointed physician to a school of gladiators. In 163–164 he visited Rome, where he resided four years. His friends offered to recommend him to the Emperor, but this honour he declined. He returned to Pergamus in 167 or 168 A.D., whence he was summoned by M. Aurelius and L. Verus to Aquileia, where they were preparing for war with the hostile tribes. He reached Aquileia in 169 A.D. just on the eve of a pestilence which caused the Emperors to set out for Rome. L. Verus died of apoplexy on the way, and G. followed M. Aurelius to the capital, where he remained several years. Of the rest of his life little is known. He is generally supposed to have died in Sicily in 200 or 201 A.D., but several authorities place his decease ten years later. G.'s personal character, learning, and accomplishments entitle him to rank with the noblest patterns of antiquity. His works, which embraced a vast variety of medical, philosophical, and miscellaneous subjects, are said to have numbered about 500. They have certainly exercised a greater influence on medical science both in the East and West than those of any other writer ancient or modern. Most of his writings that have survived are in the original Greek; a few, however, are known to us only through Latin and Arabic translations. The works extant under his name consist of 83 treatises undoubtedly genuine, 19 doubtful, 45 spurious, 19 fragments, 15 commentaries on the works of Hippocrates, and over 50 pieces, many of them undoubtedly spurious, lying still unpublished in different European libraries. G.'s works were first published in a Latin translation, Venice, 1490, and they have appeared more than twenty times in that dress. The Greek text has been published four times—at Venice (Aldine), 1525, Basel, 1538, Paris, 1679, Leipsic (Kühn's edition), 1821–33. The last two are accompanied by a Latin version. See Smith's *Dictionary of Greek and Roman Biography*, art. 'Galenus;' Ackermann's *Historia Literaria*, prefixed to Kühn's edition; Choulant, *Handbuch der Bücherkunde für die ältere Medicin;* and the Histories of Medicine by Haller, Leclerc, and Sprengel.

Galeopith'ecus. See Flying Lemur.

Gal'erites, a genus of fossil sea-urchins or *Echini* belonging to the class *Echinodermata* and to the family *Echinoconidæ*. *G. albogalerus* from the White Chalk is a familiar species, and illustrates the character of the genus and family, which consists in the possession of a central mouth having 'teeth,' the spines of the shell being small, and the apical disc having five genital plates. The members of this family are confined to Mesozoic rocks.

Gale'rius Valerius Maximianus (known as Maximian II.), Roman emperor from 305 to 311 A.D., was the son of a Dacian shepherd. In early life he followed the calling of his father, but afterwards entered the Roman army, in which he rose rapidly. In 292 A.D. Diocletian raised him along with Constantius Chlorus to the dignity of a Cæsar, gave him his daughter in marriage, and assigned him the government of Illyria and Thrace. In 305 A.D., on the abdication of Diocletian and Maximian I., he and his colleague became joint-emperors. On the death of Chlorus at York in 306 A.D., the ambition of G., who aimed at the sole power, was frustrated by the troops declaring in favour of Constantine. This disappointment was followed by the usurpation of Maxentius, before whom he retired with the loss of Italy and Africa, A.D. 307. G. died in 311 A.D. of the *morbus pedicularis*, which the Christians believed to be a punishment for his pitiless persecution of them.

Galia'ceæ, a natural order of plants of which the genus *Galium* is the type. Some authors regard it as a sub-order of *Rubiaceæ* (q. v.). The Bedstraw (q. v.), the Woodruff (q. v.), and the Goose-Grass (q. v.) belong to the order.

Galia'ni, Fernan'do, an Italian wit, scholar, and political economist, was born at Chieti, 2d December 1728. Bred for the Church, he gained notoriety by a clever squib in 1746, and deserved serious attention for a very original economical treatise, *Della Moneta*, published anonymously in 1750. G. soon obtained a place in the Neapolitan Exchequer; and in 1760 he was sent as secretary of embassy to Paris, where he was a welcome and valued guest in the brilliant circle to which Grimm, Holbach, and Diderot belonged. Recalled in 1777, he held at home various influential posts in the service of the state till his death, 30th October 1787. His wit and originality he showed in his economical writings, so that even Voltaire pronounced his *Dialoghi*

sul Commercio del Grano (French transl. 1770) to be as amusing as the best novels. G. wrote also *Della perfetta Conservatione del Grano* (1753), a treatise in 1779 on the eruption of Vesuvius, and in 1778 *Sur les Devoirs des Princes Neutres.* He maintained an extensive epistolary intercourse with European men of letters and statesmen, and at his death left a vast amount of interesting correspondence, part of which was published, 2 vols. Par. 1818–19, under the title *Correspondance inédite de G., 1765 à 1783, Avec M. d'Epinay, le Baron d'Holbach, Grimm, Diderot,* with a biographical memoir by Guingené.

Gali'cia (Ger. *Galizien*), Latinised from the Polish *Halicz*, or *Galicz* (q. v.), the name of a crown-land in the N.E. of Austro-Hungary, and on the northern slope of the Carpathians, is bounded N. by Russia, W. by Silesia, S. by Hungary and Moldavia, and E. by Russia. Area, 30,308 sq. miles; pop. (1869) 5,444,689. It forms an extensive fertile plain in the N. and E., and is watered by the Dniester and its many tributaries in the E., and by the Vistula (which forms the border for 120 miles) and its branches the San, Donajec, and Bug in the W. and centre. Nearly a half of the surface is arable, rather more than a fourth wooded, and a tenth unproductive marsh and sandy waste. The chief crops are oats, barley, flax, tobacco, and beetroot, and there is much sheep and cattle breeding and horse-rearing. G. is rich in salt (Wieliczka and Bochnia), in coal and petroleum. The mass of the inhabitants are Slavs (4,544,000), Poles in the W. and Ruthenes in the E. There are 165,300 Germans and 575,918 Jews. The Poles are mostly Roman Catholic (two archiepiscopal sees, Lemberg and Cracow); the Ruthenes belong to the Greek Church The trade, which is mainly transit, and is in the hands of the Jews and Armenians, has greatly increased since the construction of the railway from the Black Sea to Silesia. Lemberg is the capital, and Cracow the chief seat of industry The old Ruthenes were already in the 9th c. subject to Poland. Their country belonged in the 11th c. to Hungary, but reverted to Poland in the 13th c., and on the partition of 1772 became Austrian. The present crown-land embraces, besides G., the kingdom of Lodomeria, the grand duchy of Cracow, and the duchies of Auschwitz and Zator. See Lipp's *Die Verkehrs- und Handelsverhältnisse G.'s* (1870).

Galicia (anc. *Gallæcia*, 'the land of the *Gallæci* or *Calæci*,' perhaps a Gallic people), a former province in the N.W. of Spain, bounded S. by Portugal, and N. and W. by the Atlantic. Area, 11,195 sq. miles; pop. (1870) 1,989,281. It is intersected from E. to W. by several irregular ranges of the well-wooded Cantabrian mountains, reaching the sea in lofty rugged promontories, as in Capes Ortegal and Finisterre. Alternating with these are many fertile valleys, yielding corn, fruits, &c. The coast is much indented. The estuaries of the rivers, the chief of which is the Minho, with its affluents the Sil and Avia, afford several of the safest harbours in Europe (*e.g.*, Ferrol and Coruña). The chief town is Santiago. The 'Gallegos' are industrious and enterprising. In 1833 G. was divided into the provinces Coruña, Lugo, Orense, and Pontevedra.

Galicz', or properly **Halicz**, a town of Austrian Galicia, on the Dniester, 14 miles N. of Stanislawow by railway. It dates from the 12th c., and was the capital of the former principality of H. Pop. (1869) 2813.

Galigna'ni, Jean-Antoine and Guillaume, celebrated French publishers, were born in London, the former 13th October 1796, the latter 10th March 1798. Their father, who was a native of Brescia, and a skilled linguist, opened an English library at Paris in 1800, and established a *Monthly Repertory of English Literature, Arts, and Science* (1808), and the well-known *G.'s Messenger* in 1814. On his death (1821) the *Messenger* was greatly improved and enlarged by the brothers, who subsequently raised it to a highly-honoured position, adopting as its chief object the advocacy of a cordial political relationship between England and France. They each received the cross of the Legion of Honour from Louis Philippe, and were presented with a splendid silver épergne by the English Government (1866) through Lord Cowley in recognition of their efforts to promote the well-being of British subjects, and more especially for having erected the G. Hospital for distressed Englishmen, near Paris. The brothers also built the large hospital of Corbeil at their own expense. Jean-Antoine died December 1873.

Galilee (Heb. *Galil*, a 'circle' or 'circuit'), the name originally given to part of the land belonging to the tribe of Naphtali, but at the beginning of the Christian era used to denote the northernmost of the three provinces into which Palestine was divided. In this latter application it embraced an area about 50 miles long by 25 broad, corresponding nearly to the former tribal territories of Asher, Naphtali, Issachar, and Zebulon. 'Upper G.,' the northern portion, was hilly but well wooded, 'Lower G.' level and luxuriantly fertile. Late in being colonised by the Hebrews, great part of this territory remained 'G. of the nations' in Isaiah's time. The Book of the Maccabees represents G. as almost wholly peopled by heathens, and in Josephus's days the Jews of G. lived among Phœnician, Syrian, Arab, and Greek neighbours. This was especially the case in the larger towns of Tiberias, Tarichæa, and Sepphoris. The dialect of the Galileans sounded strange in the ears of a Judæan; and, doubtless owing to their intercourse with non-Jewish races, the Galileans were much less strict in their observance of the law than their southern kinsfolk. Hence 'Galilean' was a term of reproach at Jerusalem; yet after the destruction of the capital, G. became, and for four centuries continued to be, the home of Jewish learning.

The *Sea of G.*, also called the *Lake of Gennesaret* and the *Sea of Chinnereth*, bordering G. on the E., was about 12½ geographical miles long by 6 wide, and is 640 feet or more below sea-level.

Galile'i, Galile'o, the celebrated astronomer and experimental philosopher, was born at Pisa, on the 15th or 18th of February 1564. In 1581 he entered the university of his native town, with the view of studying medicine and philosophy, but these he soon forsook for the more congenial studies of mechanics and mathematics. His power of rare observation was shown, when he was scarcely nineteen years old, in connection with the swinging lamp in the cathedral of Pisa, which resulted in the discovery of the law of motion of a pendulum. Under Ostilio Ricci he made such rapid progress in mathematical studies, that in 1589 he was chosen Professor of Mathematics at Pisa. His opposition to the Aristotelian philosophy, however, so roused the hatred of the schoolmen, that he was forced, in 1592, to remove to Padua. Here his fame as a teacher attracted students from all countries; and his habit of lecturing in Italian necessitated many idiomatic modifications to suit the requirements of science. His attention had been early directed to the fall of bodies, and his demonstration at Pisa that all bodies fall from the same height in precisely the same time, was supplemented in 1602 by the discovery that the spaces described by a falling mass in successive equal intervals of time increase like the odd numbers 1, 3, 5, 7, &c., so that the whole space described from the beginning of the motion is proportional to the square of the time. The rumour of the invention in Holland of an optical instrument for observing distant objects led him, in 1610, to the construction of his telescope, which consists of a plano-convex object-glass and a plano-concave eyeglass. This he at once directed to the moon, whose surface he thus demonstrated to be uneven and rugged, and covered with mountains often far exceeding in height those on the earth. He proved its axial rotation, and discovered, but did not satisfactorily explain, its librations. With the same instrument he next examined and resolved certain nebulæ, discovered Jupiter's satellites in January 7, 1610, observed what he called the *three-bodied* character of Saturn—his telescope being too imperfect to sufficiently distinguish the ring—proved the sun's rotation, and the inclination of its axis to the ecliptic, by observing the motion of the spots, and finally demonstrated that Venus, Mercury, and Mars exhibited phases like the moon, thus dealing the death-blow to the Ptolemaic system of the universe. The history of these discoveries is narrated in his *Nuncius Sidereus* (1610). In 1611 he visited Rome, and was received with great honour; but his controversies with the Aristotelians—*i.e.*, the clergy—continued with greater virulence than ever, and resulted, in 1616, in a papal admonition through Cardinal Bellarmine not to teach publicly the Copernican system. This might have had the effect of turning him from the study of astronomy, if the appearance of three comets in 1618 had not strongly attracted his attention. In 1623 he published *Il Saggiatore*, an eloquent and masterly reply to the Jesuit Grassi, whose direct antagonism was aroused by a work written by Marco

Guiducci, G.'s pupil, but supposed by Grassi to have been written by G. himself. This could not but tend to embitter the mutual animosity, and more fuel was added to the fire by the publication in 1632 of G.'s great work, *Dialogo di Galileo G. sopra i due massimi Systemi del Mondo Tolemaico e Copernicano*, in which the Ptolemaic partisan came off decidedly the worse in the argument. This publication not only increased the enmity of the clergy, but roused the hatred of Pope Urban VIII., who had hitherto been G.'s personal friend, and accordingly in the spring of 1633 he was summoned to Rome. On the 22d of June he was brought before the Inquisitors, and forced, under fear of threatened torture, to abjure upon his knees his belief in the doctrine of Copernicus. The remainder of his life he passed chiefly at Arcetri, near Florence. In 1636 he became quite blind, just as he was completing his treatise on motion (published 1638), and deafness, sleeplessness, and other infirmities of old age severely tried him till his death on January 8, 1642. He wrote many works on subjects of natural philosophy for the use of his students, and collective editions have been published in 1718 at Florence (3 vols.), in 1744 at Padua (4 vols.), in 1808 at Milan (13 vols.), and in 1842-56 at Florence (16 vols.). His biography has been written by Viviani, his disciple, in the annals of the Florentine Academy, by Nelli (Lausanne, 1793), Brewster (Lond. 1841), Caspar (Stuttgart, 1854), Chasles (Par. 1862), and by Drinkwater in the *Library of Useful Knowledge*. See also Madden, *G. and the Inquisition* (Lond. 1863); Vosen, *G. und die Röm. Verurtheilung des Kopernikanischen Systems* (Frankf. 1865); and Gebler, *G. G. und die Römische Curie* (Stuttg. 1876). A Vatican MS. published by Signor Berti (Rome, 1876) proves that G. escaped torture only through the interposition of an influential friend.

Gal'ingale, a name sometimes applied to *Cyperus longus*, a rare plant found in England, whose tuberous roots contain a bitter principle. Hence they have been used as a tonic. See CYPERUS.

Galipea, a genus of plants belonging to the Rue family, found in tropical America. They are chiefly shrubs. The bark of several species is highly aromatic and tonic. See ANGOSTURA BARK.

Gal'ium, the typical genus of the order *Galiaceæ* (q. v.), and the generic name for the Bedstraw (q. v.).

Galiz'yn (spelt also **Galitzin** and **Golizyn**) is the name of one of the most distinguished princely families of Russia. From the time that the Princes Dmitrij and Michael commanded Russian armies in 1514 down to the present day, members of this house have at all times been prominent in Russian diplomacy or in Russian campaigns.—**Wassilij**, 'the Great G.,' born 1633, was the favourite of Sophia, Peter the Great's sister, and strove, not without success, to import Western civilisation into Russia. For aspiring to marry Sophia, he was banished to a prison on the shores of the Arctic Ocean, where he died of poison. His cousin Dmitrij headed the party which wished to restrict the authority of the Czar, and died in the dungeons of Schlüsselburg.—**Dmitrij Alexejevitch G.** (born 1735, died 1803), was the ambassador of Catharine II. at Paris and the Hague, a friend of Voltaire and the Encyclopédists. His wife, **Amalie, Princess G.**, born 21st March 1748, was the daughter of a Prussian general, Graf von Schmettau, who gathered round her at Münster a circle of brilliant authors, including Jacobi, Hamann, and Hemsterhuis, the last of whom addressed to her his *Lettres sur l'Athéisme* (1785). She was not less distinguished for accomplishments than for intense devoutness. Her own influence and that of the circle in which she moved was mainly influential in producing the extravagant religious sentimentality which for a time characterised large sections of cultured German society. She died 24th August 1806. A son of the Princess, **Dmitrij**, born in 1770, died as a Catholic missionary in N. America, 6th May 1840.

Gall. See BILE.

Gall, St., a canton in the N.E. of Switzerland, bounded N. by Thurgau and Lake Constance, E. by Vorarlberg and Lichtenstein, S. by the Grisons and Glarus, and W. by Zürich and Schwyz. Area, 747 square miles; pop. (1870) 191,015. It is very mountainous in the S., where the greatest heights are Schirbe (9000 feet) and Galanda (8800). In the N. the rich valleys and plateaux yield maize, corn, grapes, cherries, apples, &c. Partly included in G. are the Lakes Constance, Zürich, and Wallenstadt, while it is further watered by the Secz, Thur, and Tamina. It surrounds Appenell, is intersected by various lines of railway, and produces iron (at Gunzenberg), linens, muslins, cottons, embroidery, lace, glass, leather, &c. The inhabitants, who speak a Swabian dialect, comprise 38 per cent. of Protestants, 60·8 per cent. of Roman Catholics, and 1·92 Jews. The canton was formed out of the territory of the old abbey of St. Gall and various minor districts in 1805. It sends ten members to the National Council, and has a military contingent of 12,474 men and a debt of 9,000,000 francs. The local constitution (1861) is extremely democratic, the citizens exercising a veto on the transactions of the two elective chambers.

Gall, St., the capital of the Swiss canton of the same name, lies on the Steinach, 20 miles S.W. of Lake Constance and 45 E.N.E. of Zürich by railway. It is 2081 feet above the level of the sea; has important manufactures of cottons, linens, muslins, embroidery, &c.; receives the cotton goods of the W. of Switzerland; and does a large export trade with the various countries of Europe. The seat of a bishop, its chief buildings are the cathedral, rebuilt in 1756, with two towers 266 feet high; the famous abbey, founded 612, secularised 1805, still a Catholic seminary, and containing the great library of 1506 codices dating from the 3d c.; and the large cantonal school (1855), in which are a museum and a town library. The deep valley of the Seinach is spanned by a stone bridge and by a new iron railway-bridge. Pop. (1870) 16,616, of whom one-fourth are Roman Catholics.

THE ABBEY OF G. (Ger. *St. Gallen*) was raised by Pippin of Heristal in memory of St. Gallus, an Irish missionary who came with St. Columban to France, and about 612 founded a monastery here. It was largely rebuilt between 820 and 830 by the Abbot Gospertius, and during many years great wealth and architectural skill were devoted to its embellishment. In the 17th c. Mabillon found a plan of a monastery at St. G., which he conjectures to have been prepared by Eginhard for Gospertius; but from the many architectural changes which St. G. has undergone we cannot tell whether or not it was rebuilt according to this drawing, which, however, throws interesting light on the arrangement of a Benedictine monastery in the 9th c. From the 8th c. onwards St. G. was a celebrated school, and to the labours of its monks as copyists we are indebted for the preservation of several of the classics. It was specially famed for cultivating music. Though its abbots were for some time subject to the Bishop of Constance, they afterwards became independent suzerains of a large part of Switzerland, and at one time ranked as princes of the Empire. The abbey was secularised at the French Revolution, but a bishopric of St. G. was created in 1847.

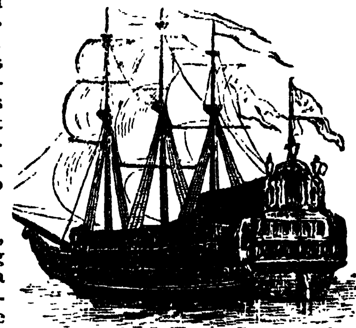
Gall, Franz Joseph, the eminent phrenologist, was born at Tiefenbrunn, near Pforzheim, in Suabia, March 9, 1758. He studied medicine at Vienna, practised as a physician, and was led to make a close examination of the structure and functions of the brain. After a series of observations conducted in lunatic asylums, prisons, courts of justice, &c., he first gave to the public his celebrated theory of mind and brain (see PHRENOLOGY) in a series of lectures at Vienna in 1796. Considerable opposition arose. G.'s views were declared to be subversive of religion and morality, and in 1802 he was prohibited from re-delivering them by the Austrian Government. Two years before, G. had made a valuable disciple in Spurzheim, who was a better anatomist and psychologist, and a more popular expositor of science than himself. M. Villers, the translator of Kant, wrote a letter to Cuvier on G.'s theory, and phrenology soon had many disciples. During a term of partnership which lasted till 1813, when they quarrelled, G. and Spurzheim made a lecturing tour in Germany, Switzerland, and Sweden, and in 1809 presented to the Institute of France, in answer to an unfavourable report by Cuvier and others, *Recherches sur le Système Nerveux en général, et sur celui du Cerveau en particulier*. This led the way to their famous work, the first edition of which appeared at Paris in 1810 under the title of *Anatomie et Physiologie du Système Nerveux*. After the quarrel with Spurzheim, who went to England, G. settled in Paris as physician, remodelled the work, and published the bulk of it as *Fonctions du Cerveau* (6 vols. Par. 1825). Fragmentary translations of this have appeared in various languages, including one in six volumes by D. Winslow Lewis, jun. (Boston, U.S. 1835). G. died at

Montrouge, near Paris, 22d August 1828; and the facts disclosed at the post-mortem examination of his body, that his skull was twice the usual thickness, and that there was a tumour in the cerebellum, caused considerable remark. Whatever may be the fate of G.'s theory, there can be no doubt about his conscientiousness as an investigator, or about his valuable discoveries in anatomy. See the works of Combe and Laycock, and for G.'s influence on philosophy, Mr. G. H. Lewes's *History of Philosophy* (3d ed. vol. ii. pp. 394-435).

Galland, Antoine, a French Orientalist, was born at Rollot in Picardy, in 1646. He travelled in the East, first in the suite of the French ambassador, and afterwards independently; was made Arabic professor in the Collége de France in 1709, and died 17th February 1715. He was a voluminous writer on numismatics, but his claim to be remembered rests on his *Mille et Une Nuits, Contes Arabes* (12 vols. Par. 1704-14), the first translation of the *Arabian Nights' Entertainments* (q. v.) into any European tongue.

Gall'a Ox, or **San'ga**, a species or variety of ox found in Abyssinia, and distinguished by the size of the horns, which form a lyre-shaped figure by their curve. The shoulder is humped, and the horns sometimes attain a length of nearly four feet.

Gallara'te, an old walled town in the province of Milan, N. Italy, 24 miles N.W. of Milan by railway. It lies at the S.E. base of the Somma Hills, and on the margin of a vast plain reaching to Milan, and yielding maize, mulberries, and vines. G. has large steam cotton-mills. Pop. 5200.



Gall'as (*i.e.*, 'invaders'), or **Oroma** (*orma*, 'men'), a large native race of E. Africa, chiefly occupying the romantic highlands in the S. and E. of Abyssinia and a tract of country S. of the river Jub. They appeared first in the 16th c. as invaders, pressing their conquests from the interior in the direction of the Red Sea, and are supposed to be only partially of negro origin, being active, intelligent, and warlike. Their colour is brown, and they have frizzled hair. Many of the G. pursue pastoral occupations in the deep valleys of Godsham and Amhara; others live by hunting and slave-trading. The majority are heathens; while there is a sprinkling of Mohammedans, and a few have accepted Coptic Christianity. See Beke *On the Origin of the G.* (Lond. 1848); Dr. James Christie, *Cholera Epidemics in E. Africa* (1876).

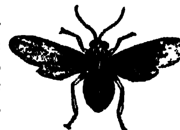
Gall'atin, Albert, L.L.D., an American statesman, was born of good family in Geneva, Switzerland, January 29, 1761. Inspired with enthusiasm for the American cause, he emigrated to the New World in 1780. Entering the army, he was for a while in command at Fort Passamaquoddy. In 1783 he became Professor of French in Harvard College, but in 1786 settled in Pennsylvania. In 1790 he was elected to the State Legislature, and entered Congress in 1795. He soon became a leader of the Republican party of that period, was the author of many brilliant financial measures, and also signalised himself as an ardent advocate of free trade. In 1801 President Jefferson made him Secretary of the Treasury, a position which he held for twelve years. He was opposed to the war with England in 1812, and he assisted in negotiating the treaty of peace at Ghent in 1814. G. was minister at the court of France (1815-23), and envoy extraordinary to Great Britain in 1826. Returning to the United States in 1827, he withdrew from political life and settled at New York. His later years were devoted to history and ethnology, and he published many papers on these subjects, and on currency, banks, and trade. He died at Astoria, Long Island, August 12, 1849. G. was a brilliant and versatile genius, and his honourable career reflected a lustre at once on his native state and on the land of his adoption.

Gall-Bladder. This is a receptacle or reservoir for the bile placed on the under surface of the right lobe of the liver. It is a pear-shaped organ, the broad end of which projects beyond the anterior border of the liver, while the narrow end terminates in a duct, called the cystic duct, which joining with the duct coming from the liver forms the common bile duct. The capacity of the G.-B. is about ten fluid drachms. It is covered by a layer of the peritoneum, or lining of the abdominal cavity, and its wall consists of a strong fibrous coat composed of connective tissue and involuntary muscular fibre, which is lined by a mucous coat. The function of the G.-B. appears to be for the purpose of storing up the bile, and of mixing it with mucous; but it would seem not to be an essential organ, as it is absent in many animals, such as the horse. See LIVER.

Galle'go, an affluent of the Ebro, rises in the Pyrenees, near the Pic du Midi d'Osan, receives the Guarga from the E., and after a course of ninety miles joins the Ebro near Zaragoza.

Gall'eon (Span. *galeon*, 'a great galley'), the name of a class of large ships formerly used by the Spaniards in war and commerce. They were tall clumsy vessels, occasionally with four gun-decks. Their towering poops were encrusted with gilding, and their bulwarks were about four feet thick. They were employed to convey treasure from S. America to Spain.

Galleon.



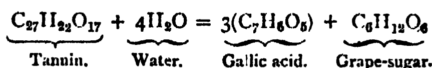
Gall'ery (Fr. *galerie*), in architecture, a long narrow room used as a passage, or for containing paintings. The name is also applied to a raised floor commonly found in old English halls, and often known as a loft. Raised wooden galleries are frequently seen in churches, and are named *rood-lofts* from having carried a large cross or *rood*. A G., *in fortification*, is a covered passage through earthwork or masonry, sometimes loopholed for firing. A G., *in mining*, is a passage from one part of the mine to another.

Gall'ey (Old Fr. *galée*, Prov. *galea*, Old Span. *galea*, Low Lat. *galea*; *cf.* Lat. *galea*, 'a helmet,' dim. *galeola*, 'a hollow vessel'), a long, low, one-decked vessel, propelled by sails or oars, and still used in the Mediterranean. The G. was the sole form of war-vessel among the ancients. (See TRIREME and NAVY.) During the middle ages galleys were the commonest class of vessels in the Mediterranean, and were only disused in naval war at the end of the 17th c. They were generally rowed by slaves chained to the oars, and it was long customary to sentence criminals in France, Spain, and other Mediterranean countries to row in them—a punishment which came into disuse in France after the reign of Louis XIV. G. is likewise applied to the general cooking-place aboard ship, and to a light swift boat belonging to a man-of-war.

Galley, or *Lymphad*, in heraldry, an ancient one-masted ship, with oars, flying colours, and furled sails. It is the emblem of the Lord of Lorne.

Galley-Slave. See BAGNES.

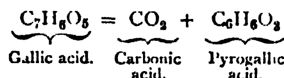
Gall-Fly (*Cynips*), a genus of Hymenopterous insects belonging to the family *Cynipidæ*, in which the antennæ are straight and the ovipositor internal. The abdomen in *Cynips* is egg-shaped, and the antennæ of the male are fifteen-jointed, those of the female possessing a joint less. The wings are large. *C. rosæ* is the *Bedeguar* of the rose, and *C. insana* forms the 'Dead Sea apples.' *C. quercus-folii* is the G.-F. of the oak-leaf, and *C. gallæ-tinctoriæ* produces the 'galls' which are so largely used in commerce in the manufacture of ink. The insects puncture the leaves and bark of trees with their ovipositors in order to deposit their eggs; the puncture of the vegetable substance is probably accompanied by the injection of some irritating fluid which has the effect of exciting an abnormal growth in the vegetable tissues; this growth finally appears as an excrescence known as a 'gall.' Within the gall the young larva undergoes development, ultimately eating its way out after attaining its mature state. The oak is frequently attacked. The best galls are gathered before the insect makes its escape, and the astringent juice is thus preserved. See GALLS.



Gall-Fly.

Gall'iard (Fr. *gaillard*, from *gai*), a sprightly dance-tune, popular 300 years ago, perhaps of Italian origin, and preceding

the *minuet*, which it resembles. Many specimens of the G. survive. Scott mentions it in his ballad of *Lochinvar*.



Gallia'te, a town in the province of Novaro, N. Italy, 4 miles E.N.E. of Novaro by railway. It has an old castle, silk and cotton mills, &c. Pop. 6700.

Gall'ic Acid is a crystalline substance contained in small quantities in gall-nuts, in the seeds of the mango, in the leaves of the arbutus, in sumach, &c. It is obtained either by allowing an aqueous solution of Tannin (q. v.) (or powdered gall-nuts moistened with water) to remain for some weeks exposed to the air, or by boiling a solution of tannin with dilute sulphuric acid. The chemical change is the same in both these processes, viz., that the tannin absorbs water and splits into G. A. and grape-sugar—

$$\underbrace{C_{27}H_{22}O_{17}}_{\text{Tannin.}} + \underbrace{4H_2O}_{\text{Water.}} = \underbrace{3(C_7H_6O_5)}_{\text{Gallic acid.}} + \underbrace{C_6H_{12}O_6}_{\text{Grape-sugar.}}$$

The crude G. A. thus obtained is purified by crystallisation from boiling water. G. A. crystallises from a hot aqueous solution in white needles, which have the composition expressed by the formula $C_7H_6O_5H_2O$. When these are heated to 100° C., they lose the molecule of water of crystallisation and become $C_7H_6O_5$. At 200° C. G. A. melts and then decomposes into carbonic acid gas and a new substance, the pyrogallic acid or pyrogallol—

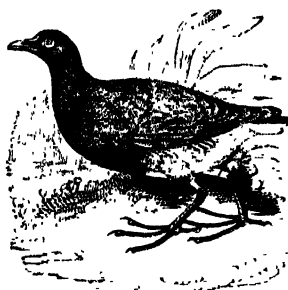
$$\underbrace{C_7H_6O_5}_{\text{Gallic acid.}} = \underbrace{CO_2}_{\text{Carbonic acid.}} + \underbrace{C_6H_6O_3}_{\text{Pyrogallic acid.}}$$

G. A. is only slightly soluble in cold water, though readily soluble in boiling water. It is also easily dissolved by alcohol and ether. Its aqueous solution reduces gold and silver from their salts, and gives with perchloride of iron a bluish-black precipitate. When G. A. is cautiously heated with concentrated sulphuric acid to a temperature of 140° C., and the solution thus obtained is poured into water, a new acid separates, called rufigallic acid, which differs from crystallised G. A. in containing no water of crystallisation. When rufigallic acid is heated to 120° C. it loses a molecule of water, and then has the composition represented by the formula $C_7H_4O_4$; at a higher temperature the acid sublimes in red crystals. Rufigallic acid dyes cloth of a fine red colour if it be mordanted with alumina. Another acid called ellagic acid separates occasionally as a yellow powder from an aqueous extract of gall-nuts which has long been exposed to the air. This acid can also be prepared by oxidising G. A. by means of arsenic acid, and is interesting as forming certain intestinal calculi called *bezoars*, which occur in the antelopes of Central Asia.

Gall'ican Church is the Roman Catholic Church in France, which has always maintained a peculiar position in relation to the Papal supremacy. The foundation of the rights which the French clergy claimed from the earliest times was an exemption in particular cases from that general control in ecclesiastical matters which was assumed by the Roman see. During the vacancy of the Papal chair after the death of Clement IV., Louis IX. of France published (1268–69) an edict against the encroachments of the popes, who had lately claimed the right of electing prelates and taxing benefices. This edict or Pragmatic Sanction (q. v.) consisted of six articles, the sixth of which preserves all privileges and immunities formerly granted, showing that there had been former edicts of a similar kind, and that the liberties then guaranteed had before been granted to the Church, but through the usurpations of the popes had in great measure been lost.

After this the anti-Papal spirit grew still stronger, fostered by the desire of the bishops to recover their authority, which had long been overridden by the popes; by the intolerable extortions and disgraceful conduct of the popes, whose authority was further greatly weakened by their dependence on the French kings during the seventy years' residence at Avignon; and by the influence of the University of Paris, at which an independent and liberal spirit was developed. At the Council of Constance, assembled 1414 to extinguish the schism between the rival popes, the principle was established which has since been regarded as the leading dogma of Gallicanism, namely, that the Pope is subject to a general council. In 1438 the Council of Basel passed several canons restricting the power of the popes. The Pope, Eugenius IV., transferred the council to Florence and rejected the canons, but the anti-Papal party continued to sit at Basel, and sought the protection of Charles VII. of France. The latter summoned the estates of his kingdom to a council at Bourges (1438), which has been called the Pragmatic Council, and which embodied in a pragmatic sanction the enactments of the councils of Constance and Basel, limiting the Papal authority in the exercise of patronage in the G. C.

This edict was the great bulwark of the liberties of the G. C., and remained in force (although Louis XI. attempted to repeal it) till 1516, when Pope Leo X. persuaded François I. to substitute for it the Concordat by which annates and some other privileges were restored to the popes, and the nomination to bishoprics and higher benefices secured to the kings. In 1682 an assembly of the clergy, called by Louis XIV. to settle a dispute between himself and certain of the bishops who opposed his claim of *régale*, or right to administer the revenues and present to vacant sees, published four propositions commonly called the 'Gallican Liberties,' and founded on the Pragmatic Sanction of 1438:—1. Neither St. Peter nor his successors received from God any power to interfere, directly or indirectly, in what concerns the temporal interests of states; kings cannot be deposed by them, nor their subjects freed from allegiance. 2. In the popes the full power over spiritual things is in such sort vested as that the Decrees of Constance concerning the authority of general councils are at the same time in full force and remain unshaken. 3. The exercise of the apostolic power is to be regulated by the canons of general councils, and the usages of the G. C. are to remain unshaken. 4. Although in questions of faith the chief place belongs to the Pope, and his decrees extend to all particular churches, yet his judgment is not unalterable, unless it have the concurrence of the Church universal.



After the Revolution the G. C. was established by a Concordat (carried into effect 1802) between Pope Pius VII. and Bonaparte, according to which bishops were to be presented to the sees by the First Consul, and the presentation confirmed by the Pope. At the same time it was enacted by the Government that no bull or missive should be received without the authority of the Government. In 1810 a decree was issued by Bonaparte confirming the Declaration of 1682. On the restoration of the Bourbons the Concordat of 1802 was annulled, and that of 1516 re-established. Since the revolution of 1848 Ultramontane principles have made rapid progress, and the once boasted liberties of the G. C. are now contended for only by a small minority in the Church. See *Report of Com. of House of Commons on the Regulations of Roman Catholic Subjects in Foreign Countries* (1816); Burnet's *Hist. of the Reformation of the Church of England* (1681–1714); *The Power of the Popes*, translated from the French (Lond. 1838); and Blunt's *Dict. of Doct. and Hist. Theology* (1872).

Gallie'nus, Publius Licinius Valerianus Egnatius, son of the Emperor Valerian, was born 218 A.D. He was associated on the throne with his father from 253 to 260 A.D., after which he became sole emperor. G. was not wanting in bravery and warlike qualities, but his victories while co-regent appear to have been a series of pompous frauds. On becoming sole ruler, he devoted himself to the most shocking debauchery. During his reign a number of usurpers, known as the *Thirty Tyrants*, scorning the feeble emperor, aspired to the purple, while foreign invaders on every side threatened the empire, the safety of which was maintained only by the energetic conduct of Claudius, Aurelian, and Probus. G., fairly roused by the gathering dangers, redeemed for a brief season his contemptible character by a singular display of valour and military skill, defeated his opponent Aureolus, and shut him up in Milan; but while pressing the siege of that city, he was murdered by his own soldiers in March 268 A.D.

Gallina'ceous Birds, or **Raso'res** (Lat. 'scrapers'), the name given to an order of *Aves* or Birds (q. v.), represented by the fowls, pheasants, partridges, pigeons, and their allies. The group is distinguished by the toes being of very strong construction and provided with blunt nails adapted for *scraping* in the ground for food. The upper mandible is vaulted and convex, and the nostrils open at its base in a membranous space, and are covered with a cartilaginous scale. The legs are stout, and feathered to the tibial and tarso-metatarsal joint. Four toes exist, the hinder one being short, and placed at a higher level than

the front toes, except in the pigeons, in which it is placed on the same level as the front ones. The food consists of seeds and grain, and a powerful *gizzard* is developed for the trituration of the food. The nests are built chiefly on the ground, and never evince any great constructive powers. The G. B. are mostly *polygamous—i.e.*, one male mates with several females; and the former are generally provided with brilliantly-coloured *wattles* and other appendages. The wings, save in the pigeons, are never very powerful. The G. B. are divided into the *Gallinacei*, represented by the fowls, partridges, &c., and the *Columbacei*, represented by the pigeons. The latter have sometimes been elevated to the rank of a distinct order. Their powers of flight are better developed than those of the *Gallinacei*, but they are less adapted for running and for a ground life than the latter. The pigeons are also *monogamous*, and pair usually for life. The young of the *Gallinacei* are *autophagous*, that is, can run about immediately after being hatched, whilst those of the pigeons are *heterophagous*, and are dependent for a longer or shorter period upon the care of the parent.

Gall'inule (*Gallinula*), a genus of Grallatorial or Wading birds, belonging to the family *Rallidæ* or Rails, and to the sub-family *Gallinulinæ*. The typical genus *Gallinula* is represented by the Waterhen (*G. chloropus*), or moorhen, whilst the other genera are *Fulica*, including the coots, and *Porphyrio*, represented by *P. veterum*, or the Hyacinthine G. of Africa, Asia, and some parts of Europe. The bill in the G. is curved at the tip; the nostrils are placed in a groove near the middle of the bill; and the second to the fourth quills are the longest of the wings. The waterhen inhabits moors and marshes. It attains a length of about 12 inches, and is coloured dark olive above, the head, neck, and under parts being of a dark grey hue. The bill is green at the tip and red at the base, and the legs and toes are green. The bird dives and swims with great ease, and is much sought after for the delicacy of its flesh.

Gallinule.

Gall iot (Fr. *galiote*, 'a half-galley'), a small two-masted Dutch vessel, flat-bottomed, bluff-bowed, and carrying a large boom mainsail. A G. has its shorter mast aft.

Gallip'oli (Gr. *Callipolis*, 'the fair city'), a fortified seaport of S. Italy, province of Lecce, on a rocky island in the Gulf of Taranto, connected with the mainland by a bridge of twelve arches. It is a bishop's see, has a castle and a cathedral (1629), and is celebrated for its olive-oil. The oil is stored for a long time in vast cisterns cut in the solid limestone, whence it is drawn for exportation in a thoroughly clarified state. G. is supplied with water by an old aqueduct, which ends in a splendid fountain bearing many fine bas-reliefs and Latin inscriptions. It is a chief station for the steam-navigation between Ancona, Messina, and Naples. The date-palm is often seen in the gardens of the beautiful villas in the vicinity. Pop. 9951. G. is the *Urbs Graia Callipolis* of the geographer Mela, and the *Anxa* of Pliny. In the middle ages it sustained many severe sieges. In 1429 it was surprised by Turkish corsairs, and many of the inhabitants were carried off.

Gallipoli (Gr. *Callipolis*, Turk. *Gelibolu*), a seaport of European Turkey, vilayet of Adrianople, on the peninsula of G., 90 miles S. of Adrianople. It is the most important town on the Dardanelles, the chief station of the Turkish fleet, is the see of a Greek bishop, and has two good harbours, an old castle, extensive bazaars, many mosques, fountains, &c. Its trade, which is in a flourishing state, is chiefly in corn, barley, cotton, oil, and wine. A magazine and cellars built by Justinian are among the antiquities in the vicinity. In 1872 the exports amounted to £128,290, the imports to £97,766. Pop. 20,000, composed of Turks, Greeks, Armenians, and Jews. G. was taken by the Turks in 1357, and formed their first European conquest.—**Peninsula of G.**, separating the Ægean Sea from the Gulf of Saros, is 55 miles long, and from 4 to 13 broad.

Gall'ipot (Dutch *gleye*, 'potter's clay,' and 'pot'), a small painted and glazed earthenware pot or jar used by apothecaries for holding medicine.

Gall'on, the standard measure of capacity for liquids and dry goods used throughout the British Islands. According to the Act of Parliament of 1826, the G. contains 10 lbs. avoirdupois of distilled water, weighed in air at a temperature of 62° F., and a barometric pressure of 30 inches. It is thus equivalent to 277·274 cubic inches. In 1825, just before the passing of the Act, there were three different gallons in common use—the dry measure, of 269; the wine measure, of 231; and the beer measure, of 282 cubic inches.

Galloon' (Fr. *galon*), a close kind of lace made of silk, or of gold or silver, in narrow width suitable for binding, trimming, &c.

Gallotann'ic Acid. See Tannin.

Gall'oway, a district in the S.W. of Scotland, now including the counties of Wigton and Kirkcudbright. There is considerable uncertainty as to the history of G., and varying extent of the territory to which the name has been given. G. seems to have been at first inhabited by the body of Picts whom Bede styles the Niduari, probably from the frontier river Nid (Nith), and who remained half independent until the 12th c. Mr. Skene contends that they were Gaelic, as they did not merge with the Cymric people around them, and long clung to a distinct dialect. The district formed for several centuries a province of the Anglian kingdom of Northumbria, and received the name *Galwydel* in Welsh, *Gallaidel* in Irish (whence the modern G.), most probably from its people being thus ruled by foreigners, from *gall*, 'a stranger,' and *Gaidhel*, the name of the Gaelic race. At one time G. seems to have been applied to the land between the Firths of Clyde and Solway. G. appears to have been practically severed from Northumbria in the 9th c., and was known as the land of the Picts till the 12th c. It was in a large degree independent of the Scottish crown until the 13th c. See Skene's *Celtic Scotland* (Edinb. 1876).

Galloway, Mull of, the most southern point of Scotland, in Wigtonshire. It forms the extremity of the Rinns of Galloway, and is a precipitous headland, supporting a lighthouse 325 feet above the sea, with a light visible for 24 miles.

Gall'ows-Bitts, a nautical term for a frame in which spare spars are held.

Galls are of great variety of form and composition, according to the plants on which they are formed and the insects producing them. Several varieties possess great economic value on account of the large proportion of tannic and gallic acid which they contain, which in some amounts to from 60 to 70 per cent. of the whole weight. These G. are very largely employed in dyeing and tanning, and for the manufacture of black ink; in addition to which, the principles they contain are valuable as astringents in medicine. The most important are known as Aleppo G. They are divided into blue, black, or grey G., which embrace such as are of a dark greenish-grey colour, and are heavy and unpunctured; and white or false G., which are light, and punctured with a channel through which the insect has escaped. The unperforated or blue G. are much more valuable than those punctured by the gall-insect. Recognised commercial varieties of these are obtained from Greece, Italy, France, and Algeria. Knoppern, or Hungarian G., constitute a peculiar variety, formed on the acorn-cups of the common oak. They are obtained in Hungary, Rumania, Styria, Piedmont, and the neighbouring countries. The Chio turpentine-tree (*Pistacia terebinthus*) bears a gall which is used for tanning and dyeing, a variety of morocco leather being tanned with it. In the East several species of *Rhus* produce G. which yield large proportions of tannic and gallic acid. A very peculiar horn-like gall is obtained in India from *Rhus kakrasinghee*; and in China hollow spherical G. are yielded by *Rhus semialata*, while a closely-allied species produces Japanese G. Tamarisk G., formed abundantly in Arabia on a species of *Tamarix*, form a sweet manna-like substance, which is regarded by the Bedouins as a great luxury; and in Australia a similar manna-gall is formed on the *Eucalyptus dumosa*.

Gall-Stone. See Calculus.

Galop, a quick dance-tune in double time.

Galt, a town in the province of Ontario, Dominion of Canada, on both banks of the Grand River, 14 miles S.W. of Guelph, on a branch of the Great Western Railway. It has good water-power, which is utilised by many flour and other mills. Pop. (1871) 3827, mostly Scotch.

Galt, John, a famous Scottish novelist, the son of a sea-captain, was born at Irvine, Ayrshire, May 2, 1779. After being a clerk in the Greenock customhouse, he went to London in 1804, with an epic on the battle of Largs, part of which appeared in the *Scots Magazine*. Failing in business, he began to study law, but his health being feeble, he was forced to travel for three years in S. Europe, where he was for a time a companion of Byron and Hobhouse. After his return G. worked on the staff of his father-in-law Dr. Tulloch's paper, the *Star*, and published *Letters from the Levant* and other works, but it was not until 1820 that his characteristic power was displayed in the *Ayrshire Legatees*, which appeared in *Blackwood*, and was cordially received. The *Annals of the Parish* (1821), his best work, established his fame, and was followed by *Sir Andrew Wylie*, *The Entail*, *The Gathering of the West*, *The Steamboat*, and the less successful historical romances of *Ringan Gilhaize*, *The Spaewife*, *Rothelan*, and *The Omen*. In 1826 G. went out to Canada as secretary to the Canada Company, but becoming at variance with the directors, returned to England in 1829 and lost his appointment. He again devoted himself to authorship, produced *Lawrie Todd*, a tale of a Scotch settler, which became very popular, *Southennan*, a romance of Queen Mary's times, and a *Life of Lord Byron*. In 1834 he came back to Scotland poverty-stricken and broken in health, and after suffering repeated shocks of paralysis, died at Greenock, April 11, 1839. G.'s poems, dramas, biographies, and essays are now deservedly forgotten, and his ambitious historical romances, though often vigorous and impressive, are wanting in animation and freshness. The modern tales, however, in which he depicts the quaint, sleepy life of Scottish provincial towns, are rich in homely humour, shrewd knowledge of character, and simple pathos, and while they have had many imitators, still possess a unique Doric flavour and a lasting popularity. See G.'s *Autobiography*, his *Literary Life and Miscellanies*, and *Memoirs* by Delta.—**Sir Alexander Tulloch G.**, son of the preceding, was born at Chelsea, September 6, 1817, and was from 1833–56 in the service of the American Land Company, becoming in 1844 manager of all their estates. In 1849 he entered the Canadian Parliament, and was finance minister 1858–62 and 1864–66. He was knighted in 1869, was one of the chief founders of the Canadian railway system, and is held to be the ablest financier in Canada.

Galva'ni, Lui'gi, an Italian physiologist, was born September 9, 1737, at Bologna, where he studied first theology, then anatomy and physiology, and became Professor of Anatomy in 1762. As a lecturer he was very popular, but his writings are few, the chief being two treatises on the urinary organs (*De Renibus atque Ureteribus Volatilium*) and on the organs of hearing of birds (*De Aure Volatilium*), and his *De Viribus Electricitatis in Motu Musculari Commentarius* (Modena, 1792). This last work treats of the results of his great discovery in 1780 of the convulsive motions of the limb of a frog in connection with an electric machine—a discovery which, in the hands of Volta (q. v.), led to the foundation of the science of current electricity. G. died at Bologna, December 4, 1798. A collection of his writings was published at Bologna in 1841.

Gal'vanised Iron is the name given to iron which has been covered by a thin coating of zinc to guard against the oxidising action of air and water. It is widely used for sheeting purposes, and is formed into telegraph wires and bolts for ships; but care must be taken that it is not placed where steam is of frequent occurrence, otherwise a rapid decomposition is the consequence. See ZINC.

Gal'vanism. See ELECTRICITY.

Gal'veston, the chief city of Texas, U.S., on G. Island, at the mouth of a bay of the same name. Its harbour, one of the best in the Gulf of Mexico, has at its entrance 12 feet of water at low tide. G. is a great centre of the cotton trade. In 1872 its exports amounted to 333,502 bales. It has also a trade in wool, hides, beeves, pecan-nuts, and beeswax. In 1874 the total exports were valued at $35,334,747. The city has street railways, and is lighted with gas. Railways connect it with the interior, and steam-ships ply between it and New Orleans and New York. G. is the see of a Roman Catholic bishop, has a Roman Catholic college, and a good medical school, two daily and four weekly newspapers. Pop. (1870) 13,818.—*G. Island*, 28 miles long, is only from 3 to 4 feet above the sea.

Gal'way, a county in the W. of Ireland, province of Connaught, is bounded E. by the Shannon and its tributary the Suck, N. by counties Mayo and Roscommon, W. by the Atlantic, and S. by county Clare and Lake Derg. Area, 2383 sq. miles; pop. (1871) 235,072. It is nearly divided into two portions by the beautiful Loughs Corrib (20 by 12 miles) and Mask, which extends into Mayo. The western portion, known as Connemara (Ir. Gael. *Conmaicne-mara*, 'the seaside tract of the children of Conmac,' a son of Fergus, King of Ulster), is a wild region of hill, glen, and morass, with a precipitous coast-line, containing many deep indentations, as Kilkieren, Birterbury, Mannin, Ballynakill, and Killary Bays. In the E. the surface is in part arable, and is watered by the Suck (a feeder of the Shannon) and its affluents. The Slieve-Baughta Mountains enter G. in the S., while in the N. of Connemara, known as 'Joyce's Country,' is the group of the celebrated Twelve Pins, some 2200 feet high. Oats and potatoes are extensively grown, and much attention is given to the rearing of a fine breed of cattle. In 1871, 230,902 acres were under tillage, 794,710 in pasture, 23,910 of plantation, and 426,600 waste, bog, mountain, &c. The lough and coast fisheries are of considerable value, while there are also manufactures of woollens, linens, friezes, &c. G. contains iron, copper, lead, marble, and limestone. It is traversed from E. to W. by the Irish Midland Railway. The chief towns are G. (the capital), Tuam, Loughrea, Athenry, and Ballinasloe. The county sends two members to Parliament. Among its many antiquities are seven round towers, various raths, cromlechs, &c.

G., BAY OF, the inlet separating the counties of G. and Clare, extends from E. to W., is 30 miles long, and has an average breadth of 10 miles. It is a splendid natural harbour, the Isles of Aran dividing its entrance into the N. and S. Sounds.

Galway, the capital of the county of the same name, Ireland, at the mouth and on both banks of the Corrib, and on the N. shore of G. Bay, 50 miles N.N.W. of Limerick and 130 W.S.W. of Dublin by railway. It is the chief town in the W. of Ireland, is the see of a bishop, and has a parish church of St. Nicholas (1320) in the Decorated English style, a Queen's College (opened 1849), Erasmus Smith's endowed collegiate school, many Roman Catholic churches, three monasteries, five nunneries, a handsome courthouse, barracks, &c. G. is a bonding port, with a floating-dock of five acres, capable of admitting vessels of 14 feet draught. The harbour light on Mutton Island is visible for 28 miles, and there are other two lights on the Arans. In 1875 there cleared the port 104 vessels, of 14,982 tons; entered 178, of 36,511 tons. The chief exports are fine marbles, corn, flour, fish, bacon, and kelp. G. has large breweries, distilleries, tanneries, foundries, flour and paper mills, &c. The extensive herring and salmon fisheries are the sole industries of the inhabitants of Claddagh (Ir. Gael. 'the muddy seashore'), a suburb forming an isolated community, where strangers are excluded, and Irish alone is spoken. The river is crossed by three bridges. Pop. (1871) of parliamentary borough, 19,843. G. returns two members to Parliament. It is doubtless an ancient place, but it first emerges clearly into history when it was seized by Richard de Burgo in 1232. In 1396 it obtained a grant of incorporation, and subsequently under Henry IV. a license to coin money. In the 16th c. a prosperous trade sprang up with Spain, which has left its trace in many old Spanish-like houses, with arms carved over their gateways. During the rebellion of 1641 the Earl of Clanricarde held G. against the Catholic insurgents, but was eventually obliged to yield to Captain Willoughby. The pestilence broke out among the terror-stricken thousands who had here sought refuge, and carried off some 3700. In 1652 G. surrendered, after a lengthened blockade, to Sir Charles Coote for the King. It was garrisoned by James II. (1690), and taken by William III.'s troops under General de Ginkell in 1691. The mails to America were despatched from G. from 1858 to 1861, and again from 1862 to 1864, in which latter year the steamer *Anglia* having struck on the Black Rocks, the line was abandoned.

Galyz'in. See GALIZYN.

Ga'ma, Dom Vasco da, discoverer of the sea route to India by the Cape of Good Hope, was born of an old family at Sines, in the Portuguese province of Alemtejo, in 1469, and was early distinguished as an enterprising sailor. The success of the expedition under Bartolommeo Diaz, who had fairly doubled the Cape (1487), encouraged King João II. to pursue the scheme of reaching India by this route. Early in the reign of João's successor Manoel, a small expedition of four ships under the command of G. sailed for India from Lisbon, 8th July 1497, and on the 20th November rounded the Cape. At Christmas they were off Natal, hence named; and thence by way of Mozambique, Mombassa in Zanguebar, and Melinda, where they secured the services of a Gujerati pilot, they reached Calicut on the Malabar coast, 20th May 1498. Through the hostility of the Moorish traders, who here, as on the African coast, recognised their hereditary enemies under the Portuguese flag, G. made no very favourable impression on the Zamori (*Samudri-Rajah*, 'the Prince of the Coast'), but satisfied with the attained results of his enterprise, sailed for home in August. He anchored in Lisbon harbour 14th July 1499, and was received with distinctions and well-merited rewards. A second expedition under G, as Admiral of the Seas of India, set out in 1502, and already in 1503 he was able to return with his thirteen ships all richly laden. G. now spent a term of years in peace at home. Meanwhile Portuguese affairs in India were far from prosperous, and in 1524 G. sailed once more for India, this time with the commission of viceroy. He had but fairly begun by his vigorous administration to re-establish order and restore the fallen Portuguese credit, when he became ill and died at Cochin, 24th December 1524. His remains were brought to Portugal, and there reinterred with all honour in 1538. G.'s character was marked not merely by the resoluteness and presence of mind necessary to every great explorer, but by a degree of good faith, uprightness, and piety unusual amongst the navigators of the 16th and 17th centuries. G.'s great achievement is the theme of the national epic of Portugal—the *Lusiad* of Camoens (q. v.). It appears that Castanheda, who even earlier than Barros wrote the history of G.'s discoveries, founded his account on the *Roteiro da Viagem que em Descolerimento da India selo Cabo de Boa Esperança fez Dom Vasco da Gama em* 1497, drawn up by Alvaro Velho, one of G.'s fellow-voyagers. The MS. of this invaluable document was discovered at Oporto by MM. Kopfe and Paiva, who published it in 1838; a French translation was made by Ferdinand Denis in 1855.

Gama Grass, a name applied to *Tripsacum dactyloides*, a grass of the Southern States of America, where it is also called buffalo grass. It is considered excellent forage, for which it is cultivated in America and Southern Europe, but it is too tender a plant for the climate of Britain.

Gama'liel (the Gr. form of the Heb. *gamliel*, 'gift,' or 'benefit of God'), the teacher of the Apostle Paul, is generally identified with the celebrated Jewish doctor, son of Rabbi Simeon, and grandson of Hillel, who was called the 'glory of the law,' who was the first to receive the title of Rabban, 'our master,' and with whose death, according to the Mishna, 'the reverence for the law ceased, and purity and abstinence died away.' He became president of the Sanhedrim, A.D. 30, and is said to have died eighteen years before the destruction of Jerusalem, or about 50. As far as the personal opinions of G. can be separated from the conclusions of the school of Hillel (q. v.), they show that he 'was endowed with great intellectual powers, a fondness for study and for definitely settling every point of difficulty, refined taste, and good judgment; that he was humane, anxious to ameliorate the condition of the helpless, a strict Pharisee, yet liberal-minded, and averse to persecute those who differ from him.' The liberality of his opinions and tastes is shown by his study of Greek literature, a taste which he seems to have communicated to his disciples (*cf.* Acts xvii. 28; 1 Cor. xv. 33; Titus i. 12); by the law he passed regarding the observance of the Sabbath, 'that all persons called to assist either at hostile invasions, or inundations, or fires, or at the falling down of houses, or even at childbirth, might walk 2000 paces in any direction;' by his humane laws that the heathen poor should have the same right as poor Jews to gather the gleanings after harvest, that Jews on meeting heathen should greet them 'Peace be with you,' and for the relief of wives and widows from the abuses to which they were exposed from unprincipled husbands and children; as also by his tolerance of the Christians (Acts v. 34–40).—**G.**, grandson of the former, who was born about 50, succeeded to the presidency about 80, and died about 116, was the teacher of Aquila, the Greek translator of the O. T., and of Onkelos, the Chaldee translator of the Pentateuch. It was he, and not the former, who sanctioned the famous prayer against all heretics, and to whom Onkelos raised a royal funeral pile. It was he, too, who put an end to the extravagant Jewish practice, so hard on the poor, of burying their dead in costly apparel, and introduced the practice, ever since followed, of burying in a simple white shroud. See Ginsburg in Kitto's *Bib. Cyclo.* (new ed. 1865), Frankel's *Hodegetica in Mischnam* (Leips. 1859).

Gamb (Fr. *jambe*, 'the leg'), in heraldry, the whole fore-leg of an animal.

Gam'ba. See VIOL DA GAMBA.

Gambett'a, Léon, a brilliant French statesman of Genoese descent, was born at Cahors, October 30, 1838. He entered at the Parisian bar in 1859, and soon became known as a fervid and trenchant orator, especially in political cases, and won great popularity from his advanced republican tenets. In 1869, on the prosecution of the *Emancipation* newspaper, he was enthusiastically received through the S. of France, and in the same year was returned to the Chamber for Paris and Marseille. In September 1870, after the fall of Napoleon III., he was made Minister of the Interior in the Government of the National Defence, and evinced conspicuous administrative energy. In October 1870 he crossed the Prussian lines round Paris in a balloon, and became head of the Delegate Government which sat at Tours. He was thenceforth for some months practically the ruler of all France unoccupied by the Germans, against whom he organised a fruitless resistance; but the Paris Government annulling his decree that former officials of the Empire should be stripped of the privileges of electors, he resigned his office and retired for a few months to Spain. He was afterwards returned to the Assembly, where he became leader of the extreme republicans. Of late (1875–76) his opinions seem to have modified, his sympathies with the Reds have cooled, and he has done much to strengthen French Liberalism by his political sagacity and moderation.

Gam'bia, a British settlement in W. Africa, consisting of Bathurst; Fort James; Fort George (M'Carthy's Island), 180 miles inland; a strip of land, 40 miles by 1, stretching along the N. bank of the river; and a triangular patch of 12 sq. miles on the S. bank, known as Cape St. Mary. Area, 21 sq. miles; pop. (1871) 14,190, of whom 80 are whites. It is a fertile country, and has a fair climate for W. Africa, the temperature ranging from 58° F. to 72° at Bathurst (where the Trades blow for some eight months); and at other parts never exceeding 96° in the shade. There is considerable commerce not only with Britain, but with France and the United States. G. imports much rice, and exports ground-nuts, wax, hides, some twisted gold rings, ivory, &c. Fort James is on an island near the mouth of the river, and Bathurst, the capital, is on St. Mary's Island, 7 miles from Cape St. Mary. G. is now subject to Sierra Leone.—G., the *river*, rises in the Tenda range, near the source of the Senegal, and flows N.W. and W. till it enters the Atlantic after a course of about 500 miles. Its mouth is 10 miles broad, and is free from bars and rollers. The G. is navigable for large vessels to Bathurst, and for vessels drawing 9 feet of water to Yabatenda, a distance inland of 300 miles.

Gam'bier, James, Lord, a British admiral, born in the Bahamas, October 13, 1756. He entered the navy when very young, became a post-captain in 1778, was engaged in the repulse of the French at Jersey in 1781, and was the first to break the French line with his ship the *Defence* in the action off Brest, June 1, 1793. He was made rear-admiral in 1795, vice-admiral in 1799, and Governor of Newfoundland in 1801. In 1807 he bombarded Copenhagen, and captured the Danish fleet of nineteen ships of the line, and many smaller vessels. He was then made a baron, and was offered, but declined, a pension. In 1808 he received command of the Channel Fleet, and in 1809 successfully attacked a French squadron off Aix, but a dispute which arose on this occasion with his subordinate, Lord Cochrane, led him to demand a court-martial, by which he was honourably acquitted. He was made Admiral of the Fleet on William IV.'s accession, and died at Iver, near Uxbridge, April 19, 1833.

Gam'bier Islands, a group of some ten coral islets in the S. Pacific, important as a station for good water, in lat. 23° 8' S., long. 134° 55' W. They are under a French protectorate.

Gam'bling. See GAMING, &c.

Gamboge', an acrid, purgative yellow gum-resin, the product of various species of the *Guttiferæ* or *Clusiaceæ* order. G. occurs in commerce in three forms :—(1) in *rolls*, (2) in *pipes*, and (3) in *cakes*, the two first being the purest. The best G. comes in the form of *pipes* from Siam, the produce of *Garcinia morella*. That which occurs in *cakes*, called Ceylon G., has been said to be derived from *Gambogia gutta*, but this is doubtful, as the tears of *G. gutta* are altogether distinct from true G. G., in combination with elaterium, bitartrate of potash, or jalap, is employed in the treatment of dropsy attended with torpidity of the bowels; in cases of obstinate constipation, and in the expulsion of tapeworm. As it occasions nausea and griping, it is best given in small doses in pill or emulsion, or dissolved in an alkaline solution, until it operates. Dose of the gum-resin :—One to five grains; of the pharmaceutical preparation *Pilula gambogiæ composita*, five to ten grains. Test :—An emulsion made with boiling water and cooled does not become green on addition of solution of iodine, indicating absence of flower or starch.

Game Laws. Hares, pheasants, partridges, grouse, heath or moor game, black game, and bustards constitute game in a legal sense of the word. Snipes, woodcocks, quails, landrails, rabbits, &c., though not game, are by the Certificate Act protected at certain seasons of the year. The Act 1 and 2 Will. IV. c. 32, made important alterations in the G. L., bringing them more into harmony with the spirit of the age than formerly. No qualification from rank or property is now required in England to entitle a man to kill game. An annual license entitles the holder to sell it. Two justices are required to try an offender, except for trespass, which may be tried by one. Appeal is allowed to the Quarter Sessions. Any one killing game on Sunday or on Christmas Day is liable to a penalty of £5, with costs. The Act imposes penalties for killing or taking a partridge between 1st February and 1st September, or pheasant from 1st February to 1st October, or black game or grouse between 10th December and 12th August (or 1st September in the counties of Somerset and Devon, and in the New Forest), or bustard between 1st March and 1st September. Hares may be killed and sold at any season. The price of a license to shoot is from £2 to £3, according to circumstances; to deal in game it is £2; the gun-license 10s. Under a lease granted subsequent to 1 and 2 Will. IV. c. 32, where there is no provision to the contrary, the tenant has the exclusive right to kill the game. When the landlord has reserved the right to himself, he may authorise others to exercise it. Justices may hold a special session as often as they think fit for the purpose of granting annual licenses to deal in game. Every licensed person must put outside his shop or stall a board with his Christian name and surname, having the words 'licensed to deal in game' upon it. Servants of licensed dealers may sell game on the premises of their employer, and one licensed dealer may sell on account of another. The provisions of the Act as regards licenses to deal in game apply to the United Kingdom. There are, however, material differences in the G. L. of England and those of Scotland. In the latter country, under a lease where there is no provision to the contrary, the game belongs to the landlord, the tenant having, however, a legal right to recompense for excessive preserving if material injury be thereby done to his crops. This right does not exist in England nor in Ireland. In Scotland possession of a Ploughgate (q. v.) of land, or leave from one having it, is required to give a title to take or kill game. Pheasants taken in lawful time, and kept in a mew or breeding-place, may be killed at any time. The Act 11 and 12 Vict. c. 30, empowers all persons having a right to kill hares in Scotland to do so, and to authorise others to do so, without a game certificate. As regards POACHING and TRESPASS IN SPORTING, see those articles. On the G. L. generally, see Irvine's *G. L.*, Paterson's *G. L.*, Levinge's *G. L.* For Scotland specially see *Stair*, B. ii. tit. 3, 68–76; *Bell's Princ.*, 948.

Laws Regarding Gamekeepers.—A corporation may appoint a gamekeeper. So may the devisee of a Manor (q. v.) in trust, and the owner of a free warren (see FORESTS, CHASES, PARKS, AND WARRENS), but the lord of a Hundred (q. v.) or Wapentake (q. v.) cannot do so. All appointments of G. must be registered with the clerk of the peace, and their powers cease on revocation of the appointment. A gamekeeper may seize guns used by persons not certified, but he cannot seize hounds or game. A park-keeper or warrener may destroy dogs pursuing deer or rabbits; but being merely owner of the land on which a dog is trespassing, though in pursuit of game, does not entitle the owner to shoot the dog. A gamekeeper is not entitled to carry or use firearms for the capture of poachers, nor can any proprietor do so.

Ga'ming, Bett'ing, Lott'eries, Laws Regarding. By 8 and 9 Vict. c. 109, keeping 'a common gaming-house' is an offence punishable by a fine of £100 or by six months' imprisonment. Gaming implements found in any suspected place are held to be proof of its being 'a common gaming-house,' and persons found in the place are held to be guilty of gaming, unless the contrary can be proved in either case. Playing for money in a public-house is not, however, necessarily an offence under the Act. To be illegal there must be an inequality of chance of winning among the players; thus if any one keeps a *bank*, with chance in his favour, the offence of gaming is committed. Games otherwise lawful, such as billiards, bagatelle, &c., are prohibited in licensed houses between one and eight o'clock A.M. and on Sundays in England and Scotland, and in England on Christmas Day and Good Friday. Any one cheating at cards, dice, or in wagering on the event of any game, sport, or pastime, and winning money by so doing, is guilty of having obtained it under *false pretence*, and punishable accordingly. All contracts, either by parole or writing, for gaming and wagering are null. The keeper of a common gaming-house is liable to a penalty of £500 or twelve months' imprisonment with hard labour. State lotteries were abolished by 4 Geo. IV. c. 60; and by 9 and 10 Will. III. c. 17, any one keeping a place for a lottery is liable to a penalty of £500. It is also an offence punishable by fine to advertise for sale any ticket or share in a foreign lottery, unless authorised by Parliament. Raffles and other devices equivalent to lotteries are also prohibited. Any one gaming or betting in any 'open or public place' may be treated as a vagrant. See BEGGARS, LAW OF ENGLAND RELATIVE TO.

Gamm'arus, a genus of *Crustacea* (q. v.) belonging to the order *Amphipoda* (q. v.), and represented by the *G. pulex* or fresh-water shrimp, common in our ponds and brooks. They swim on their side, and have slender upper antennæ.

Gam'ut, or **Gamm'ut**, the scale or series of musical sounds. For the historical meaning of the word, see NOTATION, MUSICAL.

Gan'dia, an old walled town in the Spanish province of Valencia, about 2 miles from the mouth of the river Alcoy, and 25 miles N.E. of the city of that name. Besides numerous churches, it contains an elaborately ornate palace. G. has some trade, and manufactures of linen, woollen, and silk fabrics. Pop. 7000.

Gan'do, a native African state in the Sudan, to the N.W. of Sokoto. It is traversed by the Niger, and is luxuriantly fertile, producing abundance of yams, dates, bananas, &c. The inhabitants are Fulahs, of Mohammedan faith, and are dispersed throughout various semi-independent provinces. G. is also the name of the capital, which is delightfully situated on a shallow stream, and has successful cotton-weaving industries.

Gandolf'o. See CASTEL-GANDOLFO.

Gan'ga, or **Sand-Grouse** (*Pterocles*), a genus of Rasorial birds, represented by the *P. bicinctus* of the sandy deserts of Europe, Asia, and Africa, and by the *P. setarius*, the pin-tailed S.-G. of Persia. These birds belong to the sub-family *Tetraonidæ*, or that of the true grouse, and are distinguished by the small size of the bill, the nostrils being partly hidden by membrane. The first and second quills are the longest; the tarsi are feathered. The toes are short, and united at the base by membrane.

Gan'ges (*Borra Ganga*, 'the great river'), the first river in India both in sanctity and historical associations, in agricultural and commercial utility, but in actual length surpassed by the Indus, and probably by the Brahmaputra. In some parts of its course it is called the Bhagirutti (*Bhagirathi*), a name which always marks the more holy channel; and at the head of the delta, after the

departure of the Bhagirutti southwards, the main stream is known as the Podda (*Padma*). The Bhagirutti rises in the Himalayas, in the native state of Gurhwal, issuing from under a glacier cave, the cow's mouth of Hindu legend. This spot is 13,800 feet above the sea, and the surrounding mountains tower 7000 feet higher. The stream first flows N.W. past Gangotri (q. v.) till it is joined by the Jahnuvi, which both in volume and length of course may claim to be the original river. The united stream now pursues a sinuous course, which is on the whole S.W. for 150 miles, and dashes upon the plain of Hindustan at Hurdwar (q. v.), 1024 feet above the sea, having fallen about 60 feet per mile. It has already received many tributary torrents, of which the Aluknunda is said to be at least one-half bigger than the G. itself, which takes its well-known name only after this junction. From Hurdwar it flows S. for 130 miles, and then S.E. for 350 miles to Allahabad, where it is joined on the right bank by the Jumna, its largest tributary. In the latter reach it has also received the Ramgunga, passed the town of Cawnpore, and been twice crossed by bridges of the Oude and Rohilkund Railway. In this part of its course are many shoals and rapids, and it is fordable in several places during the hot weather. Boat traffic, however, is extremely brisk at Cawnpore, 150 miles above Allahabad; large boats can go 260 miles higher, and the river is reckoned navigable as high as Hurdwar, 488 miles above Allahabad, and 1334 miles from the sea. From Allahabad it proceeds almost due E. for about 500 miles, as far as the hills of Rajmehal. This is the grandest portion of its course, in which it passes by the holy city of Benares and the great mart of Patna, and is augmented by the Gumti, Gogra, Gunduck, Bagmutti, and Cusi from the N., and by the Sone and other minor streams on the right bank. At Rajmehal it turns sharp S.E., but the deserted channel, still called the Bhagirutti, which passes under the ruins of Gaur, still marks the former course further to the E. The first offshoot that contributes to form the delta branches off from the right bank at the town of Suti, about 60 miles below Rajmehal, and 280 miles from the sea. This offshoot, which is not now easily navigable except during the rains, is also called the Bhagirutti, and preserves the sanctity which the main stream henceforth loses. Its course is almost due S. past Murshedabad, and the high bluffs of clay on the right bank indicate the western limit of the delta. After being joined by the Jellinghi, the second offshoot of the G., it presently takes the name of the Hooghly, and passing Chandernagore and Calcutta, opens into the Bay of Bengal at Saugor Island, the most S.W. mouth of the G., and the only one navigable for large ships, which can come up as high as Chandernagore, 115 miles from the sea. The total length of the river, according to the course described above, is about 1500 miles. The main stream, the Podda, after throwing off the Bhagirutti, receives the Mahanunda and other minor streams from the N., and loses several offshoots to the S. at Goalundo (q. v.), is the confluence of the Jumuna, as the Brahmaputra is here called, whose volume is far larger than that of the G. The united stream flows S.E., and after throwing off innumerable branches towards the S., is joined by the Meghna, and finally under that name enters the Bay of Bengal, amid a network of islands and marshes, at the extreme N.E. of the delta. The entire length of the G., measuring from the source of the Jahnuvi to the mouth of the Meghna, is 1570 miles. The influence of the tide is felt about 200 miles inland; and lower down the phenomenon of the 'bore' is frequently to be observed, and is occasionally productive of disastrous consequences. To understand the general character of the G., all notions derived from English or even European rivers must be laid aside. We must attempt to realise a river which receives several tributaries as large as itself, but whose average volume is not thereby augmented; which wanders over a sandy bed at least two miles broad, and changes its main channel year by year, throwing up sandbanks and habitable islands several square miles in area, and again washing them away; which rises about 30 feet, more than double its average depth, between June and October, when swollen by the annual rains, at which time it is estimated to bring down 1,350,000 cubic feet of water per second; which disperses itself in fertilising flood over thousands of square miles in the lower part of its course, and loses in backwaters and swamps the greater portion of its volume before ever it reaches the sea. The delta extends in a triangular shape, Suti being at the apex, 180 miles from the sea, and the base reaching from the Hooghly to the Meghna, more than 200 miles. The upper portion of this delta forms the most fertile portion of Bengal, where the rice crop never fails; but a wide strip along the sea, the Sunderbuns (q. v.), where the process of land-making goes on day by day, is an unsurveyed wilderness of jungle, marshes, and creeks, inhabited only by tigers and other wild animals. The total quantity of solid matter annually brought down has been estimated at 6,368,000,000 cubic feet; the area of the drainage basin at 391,000 sq. miles.

As far as the head of the delta, the services of the river to agriculture are limited to within a few miles from its banks, except where they have been artificially extended by the G. Canal (q. v.); but below that point the whole country is annually inundated, and it has been found unprofitable to attempt to interfere with this natural irrigation by means of confining embankments. In an ordinary year the floods bring down a top-dressing of silt, which renders all manure unnecessary, and even ploughing a mere form, and sometimes allows three crops to be taken off the same field in a single year. The villages are placed on high lands, artificially raised; and the peasants become boatmen during the rainy season. Occasionally, indeed, the inundation is excessive, and villages, cattle, and crops are all swept away; but such a misfortune is rare, and almost compensated by the extra fertility caused to the soil.

The utility of the G. as a means of water traffic cannot be over-estimated. The great towns on its banks, especially Cawnpore and Patna, owe their greatness to this cause; but the opening of the East Indian Railway has somewhat interfered with the native boats, especially in the upper part, and has driven steamers off the river. The total traffic registered at Sahibgunge, just above Rajmehal, in 1873 amounted to about 220,000 tons coming down stream, and about 200,000 tons going up. The exports down stream are chiefly oilseeds, pulses, wheat, sugar, saltpetre, timber, and tobacco; the imports up stream are almost confined to rice; next come salt and pulses. The down-stream traffic is most brisk during the floods; and the boats return up stream from December to April, being towed from the bank the greater part of the way. At Cawnpore, Patna, and Sahibgunge the local boat-traffic is transferred to and from the railway. From the head of the delta there are two alternate routes to Calcutta, the one straight down the Bhagirutti, which is only open during the rainy season; and the second round through the Sunderbuns, along recognised natural and artificial channels. By this latter route also comes the produce of Eastern Bengal and Assam.

The sanctity of the G. dates from the Puranic period, the second classical era of Sanskrit literature. The most popular legend is that contained in the *Ramayana*, which explains the associations which still cling to the names Ganga, Bhagirutti, Jahnuvi, and Saugor. The river is there described as being brought down from heaven to atone for unparalleled sacrilege. The most frequented spots of pilgrimage on its banks are Gangotri, Hurdwar, Allahabad, Benares, Nuddea, and Saugor Island, but ghauts or bathing places abound everywhere throughout its course. 'The offences of any man who bathes in this river are immediately expiated; and those who, even at the distance of a hundred leagues, say *Ganga, ganga*, atone for the sins committed during three previous lives.'

Ganges Canal, described in an official document as 'the greatest work of irrigation ever constructed,' is designed to irrigate the Doab, the dry tract between the Ganges and Jumna rivers, extending roughly from Delhi to Cawnpore. Its services to navigation are of secondary importance. The head of the G. C. is 2½ miles N. of Hurdwar, where the Ganges debouches from the mountains. At first it has to encounter many cross torrents, some of which are suffered to cross it on a level, others are conducted over it by bridges, and over others it passes by aqueducts. The Solani Aqueduct is 920 feet long, in 15 arches of 50 span each. The canal proceeds along the centre of the country between the two rivers, throwing off branches at intervals, of which the two largest fall into the Jumna near Etawah and into the Ganges at Cawnpore. The work, which is entirely of British origin, was commenced in 1848, and opened by Lord Dalhousie in 1854. The total length, including branches, is 614 miles, and the distributaries are an additional 3111 miles. Irrigation commences 22 miles below the headworks, and is diffused over an area 320 miles long by 50 broad. In 1872–73, there were irrigated 685,170 acres; the net profits were £70,764, or 2·74 per cent. on the capital; and the navigation returns were £3237.

A Lower G. C. was commenced in 1872, with a capacity equal to the above canal, to water the remainder of the Doab from Futtehgurh to Allahabad, at an estimated cost of £1,825,000. The water will be diverted from the Ganges by a weir at Rajghat. An Eastern G. C. has also been determined upon to irrigate 3000 sq. miles in Western Rohilkund, between the Ganges and the Ramgunga. It will pass through several miles of deep cutting.

Gan'gi, an old town of Sicily, province of Palermo, in a hilly region, 12 miles W. by N. of Nicosia. It is near the remains of the Sikelian *Enguium*, originally a Phœnician colony, where in Cicero's time was a famous temple of *Magna Mater* (or Aschera), despoiled by Verres. This older G. was destroyed by Friedrich II. in 1299. Guiseppe Salerno, a famous painter of the 17th c., was born at G., and was called *Lo Zoppo* ('the lame') *di G.* His 'Last Judgment' is in one of the churches. Pop. 10,535.

Gang'lia. These are little knots or swellings found in connection with nerves. They vary in form and size, from being almost microscopic to about half an inch in length. Each ganglion has a strong, tough, fibrous coat, composed of connective tissue, which sends partitions into its interior, dividing it into a meshwork. In this meshwork numerous large round or oval nerve-cells are found. These nerve-cells are undoubtedly in connection with nerve-fibres, of which there are usually several bundles entering into or issuing from G. G. are found on the posterior roots of each of the spinal nerves, on one of the roots of the fifth cranial nerve, in connection with the seventh pair of nerves, the glosso-pharyngeal and pneumo-gastric nerves, on the branches of certain cerebro-spinal nerves, and in connection with the sympathetic nerve. The functions of G. are not well understood, but they are generally believed either to act as reflex centres or to have an important relation to the nutrition of the nerves with which they are associated. See NERVES.

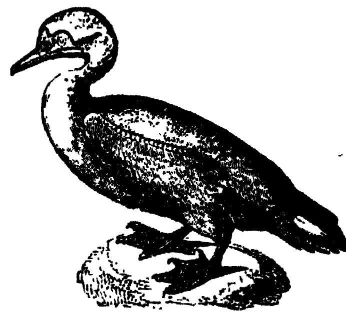
Ganglion, in surgery, is of two distinct kinds, *simple* and *compound*, the former being situated on the sheaths of tendons, and the latter consisting in a dilatation of the sheath itself. Simple ganglia consist of cysts, varying in size, containing a transparent yellowish fluid, thin and serous, or gelatinous and semi-coagulated. They are smooth, globular, and elastic, and are usually situated on the back of the wrist or dorsum of the foot. They are considered to be cystic transformations of the fringe-like processes of the synovial membrane lining the sheaths of the tendons; and they give rise to painful sensations from pressure on neighbouring parts. Compound ganglia chiefly occur in the palm of the hand and the dorsum, sole, and inner side of the foot. They often attain a large size, owing to several tendons being implicated, the sheaths of which are vascular and lined by a red fringed membrane, the fluid contents being dark and bloody, containing masses of fibrine, or granular bodies similar to those met with in certain forms of enlarged bursæ. This form of disease is extremely chronic, and may occupy a very extensive surface, frequently assuming an almost malignant appearance. Treatment:—When small and simple, they may be got rid of by being ruptured by forcible pressure, by puncturing them by means of a valvular opening, or they may be dissected out. The injection of a small quantity of the tincture of iodine, or the introduction of a seton, often effects a cure.

Gangot'ri, a place of pilgrimage high up in the Himalayas, in the state of Gurwhal. Here is a temple about 8 miles below the actual source of the Bhagirutti or Ganges, 10,319 feet above the sea, whither devout Hindus come to bathe, pay fees to the guardian Brahmins, and carry away to the plains flasks of the holy water, which is supposed to possess peculiar efficacy. Higher than this temple the pilgrims do not go.

Gangpur', one of the tributary states of Chota Nagpore, a division of the province of Bengal, British India. Area, 2484 sq. miles; pop. (1872) 73,637; estimated revenue, £2000; tribute to the British, £50. The state, which was ceded to the British in 1803, is very hilly, and overgrown with jungle. The river valleys produce rice, oilseeds, and tobacco. Diamonds and gold are found in the rivers, and coal has been ascertained to exist. The chief town is Suadi, on the Ib river, a tributary of the Mahanaddi.

Gan'grene, or **Mortifica'tion**, the local death of a part of the body, external or internal, the result of disease or injury. There are certain local phenomena common to all forms of G., such as complete loss of motion and sensation, depression of temperature, an odour of putrescence, emphysematous crackling from development of gas in the tissues, and a dark, purplish, or greenish-black colour, more or less mottled with red. In the dry form the skin shrivels, becomes dry, wrinkled, and semi-transparent, the colour of the skin being pale, tallowy white with a mottled appearance. When G. is strictly local, and the parts affected are unimportant, the constitutional symptoms are slight; but if important parts are affected, as the intestines or lungs, the symptoms are severe, comprising, first, the symptoms of inflammation, followed by great depression of the vital powers, anxietas, feeble, quick, and compressible pulse, cessation of pain, hiccup, vomiting, and death, with delirium, twitchings, and coma. Treatment:—When G. occurs in any part of the body, the part affected must be separated from the living tissues by a *natural process* or by a surgical operation. Surgical interference is applicable only when external surfaces or portions of limbs are involved, and even in such cases the necessity for operation must depend upon the nature and cause of the disease. G. invariably involves the destruction of the part affected, and if that part is essential to life, death is the necessary sequence.

Gangue is the mineral product which accompanies the ores in metalliferous veins.



Gang'way (Old Eng. *gang*, 'a going,' and *weg*, 'a way'), a narrow roped or railed platform running along a vessel's side, or from the forecastle to the quarterdeck, especially in deep-waisted ships. G. is also the name of a plank or planking for entering a ship from the shore, and of the part of a ship's side to which steps are nailed for climbing aboard.

Gan-Hwuy. See NGAN-HOI.

Ganjam', a town in the district of the same name, province of Madras, British India, 536 miles N.E. of Madras, and 315 S.W. of Calcutta. It was formerly the chief town of the district, with military cantonments and other fine buildings; but in 1815 it was desolated by a fever, and the headquarters were removed to Chicacole. It still retains some trade. Exports in 1872-73, £32,602; pop. about 5000.—*G. district* is the most northerly portion of the Madras Presidency, being bordered on the N.W., the N., and N.E. by the Bengal province of Orissa. Area, 8313 sq. miles; pop. (1871) 1,520,088. It is sharply divided into hill country, and alluvial plains. The former, which is inhabited by the aboriginal Kondhs, supplies valuable jungle products; the latter yield abundant crops of rice, maize, sugar-cane, cotton, pulses, and oilseed. Refined sugar is now largely manufactured under European supervision. The chief towns are Berhampur and the ports of Chicacole, Gopaulpur, and G. town. The seaboard has no proper harbours, but a considerable coasting trade is carried on. Exports in 1872-73, £303,097; imports, £79,521.

Gann'at, a town in the department of Allier, France, on the Andelot, a branch of the Allier, in a richly-wooded hilly district, 12 miles W. by S. of La Palisse by railway. It has tanneries, breweries, and some trade in wine, corn, cattle, &c. Pop. (1872) 5202.

Gann'et (*Sula Bassana*), a species of Natatorial birds included in the family *Pelecanidæ*, and also known by the name Solan goose. The bill is straight, and slightly curved towards the tip. The first and second quills are the longest. The tail is of graduated conformation, and the tarsi have a posterior keel. The claw of the middle toe is notched or indented, the hinder toe possessing only a rudimentary nail. A space destitute of feathers exists on the breast.

Gannet.

The average length of the bird is about 32 inches. Its colour is buff on the head and neck, the primary wing feathers being black, and the rest of the plumage white. The nest is constructed out of grass and seaweed, and one egg of a pale blue colour is laid. The G. feeds on fishes, and is especially active

in its movements during the winter and spring months when the sprat-fishing is carried on. The great home of these birds in Britain is the Bass Rock in the Firth of Forth, where they exist in large numbers, but are sometimes subjected to a wanton and indiscriminate slaughter. They are also found at Lundy Island, Ailsa Craig, St. Kilda, on the S. coast of England, Labrador, &c. The feathers are made use of, but the flesh is coarse and oily. The Booby (q. v.) (*S. fusca*) is a species nearly allied to the G.

Gan'oid Fishes, or Ganoi'dei, an order of Fishes represented by very many fossil forms (*Pterichthys*, *Cephalaspis*, *Dipterus Pteraspis*, *Coccosteus*, *Diplacanthus*, &c.), mostly found in the Devonian or Old Red Sandstone rocks, and by a few families and genera of living fishes, chief among which are the sturgeons (*Sturionidæ*), amia (*Amiadæ*), bony pikes (*Lepidosteidæ*), *Polypterus*, &c. By many naturalists the genera *Ceratodus* (the 'Barramunda' (q. v.) of Australian rivers) and *Lepidosiren* (the 'mud-fishes' of Africa and S. America) are included among the G. F., being removed from the order *Dipnoi* (q. v.). (See also FISHES.) The G. F. forming the order *Ganoidei* are distinguished by the presence of the peculiar *ganoid* (Gr. *ganos*, 'splendour') scales, which consist of hard plates of bone, coated with a kind of enamel known as *ganoine*. These scales are placed edge to edge, and are generally articulated together by means of processes, so as to envelop the fishes in a kind of armour. Ganoid scales, it may be noted, are found in one or two groups (*Lophobranchii* and *Plectognathi*) of the Teleostean order of fishes. The endoskeleton of G. F. is usually imperfect, the spine and skull frequently remaining cartilaginous throughout life. Both sets of paired fins—*pectorals* and *ventrals*—are present, the latter being abdominal in position. The tail fin is *heterocercal*. The swimming-bladder is provided with a duct, and the intestine has a spiral coil. The heart has an auricle and ventricle, and a contractile arterial bulb, which is provided with several rows of valves.

Gant'let, or **Gaunt'let** (Fr. *gantelet*, from *gant*, 'a glove'), an armed glove worn by knights in armour. Prior to its introduction in the reign of Edward I. the hand was protected by a bag or mitten of mail attached to the sleeve of the hauberk. The first G. had separate fingers, and was formed of leather covered with scales or overlapping plates of iron. The G. was thrown down in token of challenge; 'to take up the G.' was to accept the challenge. 'To run the G.' means to pass quickly between two rows of soldiers or sailors, and be scourged by each. G. in this connection is a corruption of the Swed. *gattlopp*, from *gata*, 'a street or lane,' and *lopp*, 'a leaping.'

Gan'tung Pass, between the feudatory state of Bussahir, in the Punjab, and Tibet, crosses the Western Himalayas at a height of 18,295 feet, and is covered with perpetual snow. It is overhung by a peak 3000 feet higher than itself, and presents a wild and savage appearance.

Ganyme'des, in Greek mythology, a beautiful youth, son of Tros and Callirhoë, carried to Olympus by Zeus, where he was made cup-bearer to the immortals. According to Homer, G. was transported to heaven by the gods in general, while other myths make Zeus bear him to Olympus, either in his own shape, or in the form of an eagle, or by means of the eagle. G. is also said to have been beloved by Zeus, and to have been carried off from Mount Ida. The story was the subject of innumerable sculptures, paintings, and cameos. G. is usually represented as a youth of exquisite loveliness, with a Phrygian cap, and with the eagle standing beside him, or bearing him through the sky. Horace describes him as yellow-haired (*Ganymede flavo*).

Gaol. See PRISON.

Gaol Deliv'ery, Commiss'ion of, is one of the five commissions under which judges of assize in England discharge their duties when on circuit. It commands two or more of the judges and other law officers of the crown on circuit to try prisoners or those on bail at the date of the commission. The court has power to suppress publication of procedure before it till the end of the trial, and to punish infraction of its order as contempt of court.

Gaol'ers and Offi'cers. To oppose an officer in the execution of his duty in a criminal case makes the opposer an accomplice in the crime (see for Scotch law, DEFORCEMENT); and if he kill the officer, he is guilty of murder. If the officer kill the opposer, it is justifiable homicide. Gaolers permitting the sale of spirituous or fermented liquors in prison are liable to a penalty of £20. They have power to punish certain breaches of discipline by keeping the offender on bread and water for a period not exceeding three days. They are required to attend the Quarter Sessions, to report the state of prisons, and to keep regular books, which are to be examined periodically; and lists of prisoners tried for felony are to be transmitted to the Home Secretary of State; omission so to do entails a penalty of £20. Under the Act persons introducing or attempting to introduce letters or other articles not allowed by the rules of the prison may be fined; and any officer of the prison so doing forfeits his office.

Gap, chief town of the French department of Hautes Alpes, on the Luye, 50 miles S.E. of Grenoble. It is ill built, and in spite of its manufactures of linen, silk, cotton, leather, and agricultural implements, has a far from thriving appearance. The cathedral is handsome. G. is the ancient *Vapinicium*. It was destroyed successively by Goths, Lombards, and Saracens. Between the plague of 1630 and the Revocation of the Edict of Nantes G. was nearly depopulated, and in 1690 it was sacked and burned. The pop. in 1872 was 6938.

Ga'per Shell, the popular name of a well-known genus of Lamellibranchiate (q. v.) *Mollusca*, scientifically known as the *Mya arenaria*. The shell is common on many parts of the British coasts, the animal burrowing in sand and mud, and possessing long siphons or breathing-tubes for the purpose of conveying water to the gills. It is much sought after for bait, and is also eaten in many districts. The family *Myacidæ* is distinguished by the thick shell with 'gapes' behind, and by the foot being of small size. The genus *Mya* itself possesses an oblong shell, a straight 'foot,' a siphon fringed at its extremity, while the gills do not project into the siphon.

Gapes, a disease of fowls and other Rasorial birds depending upon the presence in the trachea or windpipe of small parasitic worms, allied to the Flukes (q. v.), and named *Fasciola trachealis*. These worms attain a length of three-quarters of an inch. The disease is named 'G.' from the worms causing the bird to frequently open its mouth as if anxious to get rid of its troublesome guests. An oiled feather introduced into the bird's windpipe dislodges them.

Gar'ancin, a dyeing substance prepared from Madder Root (q. v.) by the action of sulphuric acid. To prepare G., madder is first treated for a few hours with water which has been acidulated, and afterwards it is acted on with strong sulphuric acid, which is added to it to the extent of 30 per cent. of the weight of madder under treatment. The mixture of madder and acid is kept boiling in a covered tank by means of steam for about four hours, after which it is repeatedly washed with pure water in a tank having a perforated false bottom. The washed product when drained, dried, pressed into a cake, and ground to a fine powder constitutes the G. of commerce. One hundred parts of madder yield from 34 to 37 parts of G., but the tinctorial effect of the product is much greater than that of the original dye-stuff. The acid is supposed to disintegrate a certain proportion of the woody fibre of the roots, and to bring the tinctorial principle into a more readily soluble condition. G. is more easily and expeditiously applied in calico-printing than madder, but it does not possess the solidity and permanence of that dye. The introduction of artificial alizarine has greatly decreased its importance.

Gar'anceux, a dye prepared from spent madder in the same way that garancin is made from the unexhausted roots. See GARANCIN.

Garay, János, a Hungarian poet and journalist, was born at Zsekzard, in Tolna county, Hungary, 10th October 1812, studied at Fünfkirchen and Pesth, and spent his life in editing various native papers. He died at Pesth, 5th November 1853. G. wrote dramas, tales, and poems, mostly of a historical character. They were published in a collected form by Franz Ney at Pesth in the year of the author's death (German selection and translation by Kertbeny, 2d ed. Vienna, 1857). The most notable are *Csab* (1835) and *Arbocz* (1837), tragedies; *Országh Ilona* (1837) and *Bátory Erzsebet* (1840), historical dramas; and

his *Arpadok* (1847), a splendid cycle of historic ballads. Some of G.'s pieces are reckoned among the pearls of Hungarian literature.

Garb, or **Garbe** (Old Fr. *garbe*, Mod. Fr. *gerbe*, from Old High Ger. *garba*, 'a sheaf'), in heraldry, a sheaf of wheat; or, if it is not blazoned, a G. simply of any other grain.

Garba'les Dec'imæ mean in the law of Scotland the tithes of corn. They were also termed *decimæ rectoriæ*, or parsonage tithes. (See TEINDS.) The word G. is from the Old High Ger. *garba*, 'a sheaf.'

Gar'cia, Manuel, was born at Seville, Spain, in 1775, and was first a chorister in Seville Cathedral. After gaining distinction as an operatic tenor at Cadiz, Madrid, Paris, and Naples, he sang in London and Paris from 1818 to 1824. In 1825 he took a select operatic company to the United States and Mexico, but was not fortunate. In his latter years he taught singing at Paris, where he died, 9th June 1832. His eldest daughter, **Maria Felicita**, was the famous Madame Malibran (q. v.); his second daughter is **Pauline Viardot-G.** (q. v.). His son **Manuel**, born at Madrid in 1805, became a teacher of singing at the Paris Conservatoire in 1835, and afterwards in London. His *École de G.* (Par. 1841; 4th ed. 1856) has won him an honourable name in musical literature.

Garcilass'o (abbreviated for **Garcias Lasso**) **de la Vega**, known as the *Inca*, was the son of a Spanish *conquistador* and governor of Peru, and was born at Cuzco about 1540. Descended on the mother's side from the old royal Peruvian stock, he was well fitted both by his sympathies and his acquaintance with the native language for his life-work, the investigation of Peruvian history. Though always zealous to be a good Spaniard and Catholic, G.'s popularity with the aborigines excited suspicion at home. He was finally ordered to return to Spain, and was interned at Valladolid. He died there in 1620. G.'s history of the Incas (*Los Comentarios reales que tratan del Origen de los Incas*) was published at Lisbon (2 vols. 1609–17), and repeatedly translated into French. A continuation of this work, *Historia general del Peru*, appeared in 1616, and was often republished before 1730. There is an English translation by Sir Paul Rycaut (Lond. 1688). G.'s work is the great source of our knowledge of the ancient Peruvians.

Garcilasso (a contraction of **Garcias Lasso**) **de la Vega**, a Spanish poet, was born of a noble family at Toledo in 1500 or 1503. His father received the name Vega from King Ferdinand in recognition of his bravery in combat on the Vega, or plain of Grenada. G. went when young to the Spanish court, and in 1529 was one of a Spanish corps which distinguished itself against the Turks in Austria. At this time he became entangled in an intrigue between a court lady and one of his relatives, incurred the Emperor's dislike, and was imprisoned on an island in the Danube, where he composed several melancholy poems. Regaining the imperial favour, he accompanied Karl V. in his expedition against Tunis in 1535, and during the following year was given an important command; but on the Emperor invading Provence, was mortally wounded near Frejus, at a fortified tower, of which he was the first to mount the breach. G. died shortly afterwards at Nice, November 1536. His poems (first published in 1543) include eclogues, sonnets, epistles, and cançiones. He imitated Petrarch, Ariosto, and Sannazarro, and, following the example of his contemporary Boscan, introduced the Italian poetic style and hendecasyllabic measure into Spain. His first eclogue is one of the most precious treasures of the national literature. His active military life finds no reflex in his verse, which is pervaded by tender, and at times even effeminate, pensiveness, expressed in language occasionally diffuse and affected, but singularly copious and graceful, and full of rich languid melody. The best edition of G.'s poems is that of Azara (Mad. 1765). There is an English translation by Wiffen (Lond. 1823). See Sismondi's *Literature of the South of Europe* (1846), and Ticknor's *History of Spanish Literature* (New York, 1849).

Garcin'ia, a genus of plants of the natural order *Guttiferæ* (q. v.), to which the Mangosteen (q. v.) and Gamboge (q. v.) belong.

Gard, a department of France, lies between the Cevennes and the Rhone, and is bounded S. by the Mediterranean, and N. by Ardèche. Area, 2252 sq. miles; pop. (1872) 420,131. It is hilly in the N. and W., slopes gradually towards the Rhone and the sea, and has a marshy coast-line of 10 miles. Rich tracts along the Rhone, G., Herault, Vidorra, and Ceze produce wine (26,000,000 gallons yearly), olives, and mulberry. G. is noted for its silk-culture, its cattle, and a fine breed of white horses. Its minerals include coal, iron, lead, sulphur, zinc, and salt, while it has large exports of dyeing and medicinal plants. The chief manufactures are silks, woollens, cottons, ribbons, and gloves. G. is traversed by a branch line of the Tarascon à Cette railway. Nîmes is the chief town; others are Alais, Uzès, and Vigan. The *Pont du G.*, 15 miles N.E. of Nîmes, is one of the grandest Roman relics in France. It is an aqueduct, and is supposed to have been built by Agrippa to convey water to Nîmes.

Gar'da, Lago di (Lat. *Lacus Benacus*), the largest lake of Italy, lies between the territory of Trent, in the Italian Tyrol, and the provinces of Verona, Brescia, and Mantua. On both sides rugged Alpine masses, opening here and there in smiling valleys, are mirrored in its singularly clear waters. Beautiful villas are dotted along its shores, and on the Sermione (Lat. *Sirmio*), a tiny peninsula, are the remains of the country seat of Catullus. The lake is 32 miles long, from 2 to 10 broad, and its greatest ascertained depth is 1900 feet. It contains the islands Trimelone, Olivé, and St. Pietro, and receives the Sarca and many minor streams, while its only outlet is the Mincio, a tributary of the Po. The name is derived from the village of G. (pop. 3000) on the E. shore.

Gardai'a, or **Gharda'ja**, a walled town in the S. of Algeria, on the N. border of the Sahara, 315 miles S.S.E. of Algiers. It is girt with orchards, watered from many deep wells, has six mosques, and carries on a large caravan trade, chiefly in oil, gold-dust, ivory, woollens, cottons, indigo, and dates. Pop. 13,000.

Gar'dant, or **Guardant**, an heraldic term, applied to beasts of prey when they are looking toward the spectator.

Gardele'gen, earlier **Gardeleben** and **Garleben**, a town of Prussian Saxony, on the Milde, 28 miles N.N.W. of Magdeburg. It has a well-endowed hospital founded in 1285, some tanneries, distilleries, and mills, and five yearly fairs. The town was once noted for its beer. Pop. (1871) 6266.

Garde Nationale, of France, was a guard of armed citizens instituted in Paris to protect liberty and preserve order, July 13, 1789. Similar bodies had previously been maintained in other French towns. The colours of the G. N. were red and blue, to which white was afterwards added, whence arose the famous tricolor. It numbered at first 48,000 men, but being organised throughout the country, speedily comprised 300,000. The G. N. offered no check to the excesses of the revolutionists until 1795, when it helped to disarm the mob of Paris. It was maintained in efficiency by Napoleon, and its members took a large part in the revolution of 1830, though it had been nominally abolished but not disarmed by Charles X. Under Louis Philippe it grew in power and republican tendencies, and in 1848 supported the revolutionists, but it was generally opposed to the Socialist party. Its privileges were largely curtailed in 1852, when it was placed beneath strict Government control, and in 1871 it was dissolved by a decree of the National Assembly.

Gar'dener's Gar'ters, the popular name given to the variegated variety of *Phalaris arundinacea*, a grass frequently cultivated in cottage gardens.

Garde'nia, a genus of trees and shrubs belonging to the natural order *Cinchonaceæ* (q. v.), found in Asia and in Africa. Several species are cultivated in hothouses for their beautiful and fragrant blossoms, such as *G. florida*, the Cape jasmine, which has double flowers, and *G. Stanleyana*. A fragrant resin is obtained from *G. gummifera*, in India, where also the fruit of *G. campanulata* is said to be used as a cathartic, and to take stains out of silk.

Gar'dening. See HORTICULTURE.

Gar'dens or Orchards, Stealing from. By 24 and 25 Vict. c. 96, to steal or injure with intent to steal any plant or fruit growing in a garden, orchard, nursery ground, hothouse, greenhouse, or conservatory, makes the offender liable to six month's imprisonment with or without hard labour, or to pay £20 above the value of the article stolen, or of the injury done. A second conviction renders the offender liable to penal servitude for three years.

Garden Spider. See EPEIRA.

Gardes Suisses, a famous corps in the French army formed in 1616. They numbered about 2000, and at the French Revolution made a desperate defence of the Louvre against the Parisians, August 10, 1792, when they were massacred almost to a man. The corps was re-organised in 1815, and disbanded in 1830.

Garde-Visure', in heraldry, the visor, or front part of the helmet.

Gar'diner, a town of Kennebec county, Maine, U.S., on the right bank of the Kennebec, and on the Maine Central Railway. The Cobossec, with a fall of 133 feet in a mile, affording valuable water-power, here enters the Kennebec. The industries of G. include saw and paper mills, woollen goods, furniture, tanning, and ice. Pop. (1870) 4497.

Gardiner, Colonel James, a soldier noted for his bravery and piety, was the son of Captain Philip G., and was born at Carriden, Linlithgowshire, January 11, 1688. He entered the Dutch service at an early age, but exchanged it for the English under Marlborough, and was wounded at Ramilies in 1706. G., who became aide-de-camp to the Earl of Stair, had a reputation at once for great courage and profligacy. According to Doddridge, who says that he had his information from G. himself, he was converted to Christianity in an almost supernatural manner in the year 1719. The accuracy of Doddridge's narrative is denied by Dr. Alexander Carlyle in his *Autobiography* (Edinb. 1860). The fact, however, unquestionably is, that after this period G. certainly became a pronounced Christian. In 1743 he was appointed colonel of a new regiment of dragoons, but was killed in an attempt to beat back the onset of Prince Charles Edward and the Highlanders at the battle of Prestonpans, September 21, 1745. See Doddridge's *Life of Col. Gardiner* (1747).

Gardiner, Stephen, Bishop of Winchester, born at Bury St. Edmunds in 1483, was the illegitimate son of Lionel Woodville, brother-in-law of Edward IV. He studied at Trinity College, Cambridge, and entered political life as secretary to Cardinal Wolsey. Gaining the favour of Henry VIII. by his efforts to secure that monarch's divorce from Catharine of Aragon, G. received rapid promotion as politician and churchman, being made Secretary of State, special ambassador to France and Germany, and (1531) Bishop of Winchester. For a time it seemed likely that he would fall before Thomas Cromwell on account of his objections to a genuine reformation, which are all the more remarkable that he wrote a work, *De Vera Obedientia*, in favour of the doctrine of the king's supremacy in the Church; yet he not only survived that statesman, but aided in his overthrow. He fell into disgrace, however, through his opposition to Catharine Parr, and during the reign of Edward VI. was imprisoned and deprived of his bishopric. The accession of Mary, on the other hand, made him the first subject in England; he was restored to the bishopric, was made Lord Chancellor and Prime Minister, and officiated at the marriage of Mary and Philip of Spain. The infamy of the persecutions of this reign is often assigned to him, but according to Lingard 'more from conjecture and prejudice than from real information.' He died 12th November 1555. Among G.'s other works are *The Necessary Doctrine of a Christian Man* (1543), the authorship of a portion of which is ascribed to Cranmer; and *Confutatio Cavillationis* (1552). See Maitland's *Essays on the Reformation*, and Froude's *History of England*.

Garess'io, an old town of N. Italy, province of Coni, on the Tanaro, at the N. base of the Maritime Alps, 45 miles W. by S. of Genoa. It has many Roman remains, and in the vicinity are quarries of fine marble (*Persigliano*). Pop. 6500.

Gar-Fish (*Belone vulgaris*), a name given to a species of Teleostean fishes, belonging to the family Esocidæ (q. v.), or pikes, and distinguished by its long and slender body, and by the length of its jaws. The G.-F. is also known by the names 'sea-pike,' 'long-bill,' 'sea-needle,' 'green-bone' (from the colour of the bones after boiling), and by other terms. Its average length is 2 feet; its colour a dark or bluish-green above, and silvery white below. It obtains the name of 'mackerel guide,' from the fact that it invariably appears before the mackerel: a circumstance probably due to the proximity of the spawning seasons.

Gar'ganey, Gargany, or **Summer Teal** (*Pterveyanea circia*), a species of *Anatinæ* or Ducks, closely allied to the Teals (q. v.), rarely found in Britain, but common in S. Europe, in India, in Africa, and distributed pretty generally over the Old World. The G. is somewhat larger than the teal. Its colour is a dark brown, variegated with white, the eye being marked above by a conspicuous white streak running backwards into the neck. The flesh of the bird is palatable and nutritious.

Garga'no, a mass of mountains in the province of Foggia, Italy, running for 20 miles into the Adriatic, and also stretching for some distance inland, but severed from the Apeninnes by a wide plain. It is wild and sterile on the S., but on the N. is richly wooded, and contains many picturesque gorges and ravines. Its highest point is 5120 feet above the sea. G. consists mostly of limestone, and has large alabaster quarries. It is the ancient *Garganus* which Horace speaks of as covered with oaks, and praises for its fine honey, an article for which G. is still famed. Horace's name *Matinus* still clings to the village Mattinasa S. of G.

Gar'garus. See IDA.

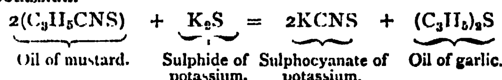
Gar'gle, or **Gar'garism,** a liquid preparation for washing the mouth and throat. Gargles are used for cleansing the parts, and also as topical applications in diseases of the mouth and throat, as in relaxed sore throat, inflammation, ulceration, &c. For such purposes alum, borax, capsicum, myrrh, chlorate of potass, and permanganate of potass, and Condy's fluid are used. A useful G. may be prepared thus:—Borax, 1 dr.; honey, 2 drs.; water, 4 oz.

Gar'goyle, or **Gur'goyle** (Fr. *gargville*, 'a waterspout;' *gargnillu*; Ital. *gargagliare*; compare with *gurgle*, 'to murmur'), in Gothic architecture is a projecting spout to discharge the water from the gutter of the roof. It was generally carved into a grotesque figure of a man, animal, or monster, from whose mouth the water was often made to gush. Gargoyles were sometimes caricatures of real persons. They seem to have been first used in the Early English style. They are generally longer on old French and Flemish than on English buildings.

Garibal'di, Giusepp'e, was born at Nice, July 22, 1807. Under his father, a poor man who owned a little coasting vessel, G. took to the sea, and made numerous voyages to Odessa, Genoa, Rome, and other ports. In 1830 he was himself in command of a trading vessel, *Notre Dame de Grace*. About this time his deep and fervid nature became impressed with patriotic sentiments. In 1833 he made the acquaintance of Mazzini, and entered heartily into the Liberal movements of the time for the regeneration of Italy. Sharing in a revolutionary movement at Genoa (1834), he had to flee, first to France, then to Africa, where he offered his services to the Bey of Tunis, and finally to S. America, where he fought in the interest of republican freedom for Rio Grande against Brazil, and for Paraguay against Rosas, the dictator of Buenos Ayres. This period in his history gave G. considerable military experience. In 1848 revolutionary movements in Italy brought him back to his native country. He commanded the forces of the Provisional Government in Rome, fought with heroic but unavailing courage against the French army, and only left the city when Oudinot began to enter it. His retreat in a N.E. direction to the Adriatic, through a country overrun with Austrian soldiery, can still be followed with breathless interest. His beloved wife Anita, the companion of all his perils, succumbed to the hardships of the march, but G. himself finally reached Genoa in safety. Thence he went to Tunis, but was forced to leave through the intrigues of the French consul. He was sent to the Isle of Maddalena, where he lived as a kind of state-prisoner till 1851, and during some hunting and fishing tours made his first acquaintance with Caprera, his future home. Thence he went to America, made some money in trade, came back to Italy in 1854, and bought the northern part of Caprera. Here he occupied himself quietly in farming for some years. The Franco-Sardinian war with Austria in 1859 induced G. to offer his sword to King Victor Emanuel; and as a leader of volunteers he gained many small victories over the Austrians. The next year he attained the height of his military success in the brilliant Sicilian campaign. Leaving Genoa with about 1000 volunteers, he landed at Marsala, 11th May; four days later won a decisive victory over the Royalist troops at Catalfimi, and took Palermo. The battle of Melazzo, July 20, placed

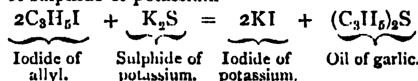
Messina and the whole of Sicily in his possession. Next month he crossed to Calabria. Volunteers in thousands joined his standard; he entered Naples without striking a blow, and was proclaimed Dictator. A desperate attack on the part of the Royalists on the Garibaldian army stationed on the Volturno failed; King Victor Emanuel at the head of his army marched to the scene of action; G. saluted him as 'King of Italy,' Gaeta capitulated, and the hero withdrew to Caprera. In 1862 he made a second descent on Sicily, with the view of driving the French out of Rome and securing the city for the Italian people. The situation was embarrassing to the Government, who could not afford to break with France. At last an Italian force was sent against the rash patriot, who was wounded and captured on the 29th of August at Aspromonte in Calabria. Pardoned by the Italian Government for his indiscretion (as he always has been), he returned to Caprera. In 1864 he visited England, and was received with unprecedented enthusiasm, but suddenly and not very intelligibly returned to Italy in the Duke of Sutherland's yacht. In 1866 the war with Austria brought him to the front as a leader of irregulars in the Tyrol, but he was unable to accomplish much. Next year all attempts to prevent him making an invasion of Pontifical territory failed. At the head of a band of volunteers he beat the Pontifical troops at Monte Astundo (October 26th), but these being reinforced by French, he was defeated at Mentana (November 4th). Once more arrested and set at liberty, he did not appear much in public until the collapse of the Third Empire during the Franco-German war made him offer his services to the new republic, and even then, although appointed commander of the army of the Vosges, he could do little beyond showing his personal gallantry. In 1871 he resigned the post to which he had been elected as representative to the National Assembly at Bordeaux, but took his seat as a member of the Italian Parliament at Rome, June 25, 1875. He has frequently owned and disowned his king, but has lately been reconciled to him with a view to getting the assistance for the scheme, now abandoned, of draining the Campagna, giving another course to the Tiber, and a new port to Rome. G. has come before the world both as poet and novelist, but none of his efforts have added to his fame. The biographies of G. are innumerable; that of Cuneo (Turin, 1865) is probably the best. G. has two sons, **Menotti** and **Ricciotti G.**, both of whom have appeared by the side of their father on the field of battle. Menotti took part in the disastrous campaign of 1862, and also in the Franco-Prussian war on the side of the Republic.

Gar'iep. See ORANGE RIVER.



Gariglia'no (perhaps from Arabic *garil*, 'a marsh'), a river which rises W. of Lake Tricino, in the Central Apennines, flows through Campania in a slow stream, and enters the Bay of Gaeta at Cangliano. Its chief affluent is the Sacco. In its lower course it traverses marshy unhealthy districts. It was anciently named the *Liris*, and more anciently the *Clanis* or *Glanis*. It separated Latium from Campania. Horace notices its gentle current (Carm. I. xxxi. 7, 8.).

Gar'lic, the common name for *Allium sativum*, a bulbous plant belonging to the Lily family, and a native of Southern Europe. The bulb, which is composed of several small bulblets called cloves, is the part which is used. G. is extensively employed in Spain, Italy, and other parts of Europe for flavouring dishes. Among the Greeks and Romans it formed a favourite viand even of the common people. Several species of *Allium* (q. v.) are popularly known as G.



Broad-Leaved Garlic (*Allium ursinum*).

Garlic, Oil of. When the bulbs of the garlic (*Allium sativum*) are distilled with water, an oily liquid passes over and condenses in the receiver along with the water, from which it may be separated by decantation. This is the crude O. of G., which may, however, be purified by rectification. From 50 kilogrammes of garlic not more than from 100 to 120 grammes of the crude oil can be obtained. O. of G. is also contained in the different parts of several species of the *Cruciferæ* and asphodels. It is present in onions, together with oil of mustard in the leaves and grains of *Thlaspi arvense* and of *Iberis amara*, in the leaves of *Alliaria officinalis*, &c. O. of G. does not always exist ready formed in the different plants from which it may be obtained, but appears to be produced by a species of fermentation similar to that which gives rise to oil of mustard from the myronate of potash contained in mustard seed. O. of G. when pure is the sulphide of allyl, and has the composition represented by the formula $(C_3H_5)_2S$. The crude oil contains small quantities of oxide of allyl $(C_3H_5)_2O$, and of bisulphide of allyl $(C_3H_5)_2S_2$. Pure O. of G. is colourless, transparent, slightly soluble in water, readily soluble in alchol and ether. It has the peculiar and characteristic odour of the garlic. It boils at 140° C. O. of G. has been prepared artificially from oil of mustard, which is the sulphocyanate of allyl (C_3H_5CNS), by heating it with sulphide of potassium—

It has also been obtained from the iodide of allyl (C_3H_5I), prepared from glycerine $(C_3H_5(OH)_3)$ by mixing it with an alcoholic solution of sulphide of potassium—

For compounds of allyl see OIL OF MUSTARD.

Gar'net, a mineral group belonging to the monometric system of crystallisation, the most common form being the dodecahedron. It is of various colours, has a vitreous lustre, is brittle, and from 6·5 to 7·5 in the scale of hardness. It occurs abundantly in mica slate, hornblende slate, and gneiss, and is also found in granite, granular limestone, serpentine, and lava. G. is a compound of four silicates (alumina, lime, iron, manganese), which in varying proportions give rise to the different varieties. *Precious G.* or *almandine*, the best specimens of which are from Pegu, Ceylon, and Greenland, is of a clear deep-red colour, sometimes almost black; *cinnamon stone*, from Ceylon and Sweden, is light yellow in colour with a high lustre, *melanite* or *black G.* occurs in the lavas of Vesuvius; *grossularite*, a green variety, is got from Siberia and Norway; *ouvarovite*, of a rich emerald shade, from Bissersk in Russia; and *aplome*, deep brown or orange in colour, from Siberia and Saxony. *Common G.* is brownish red, imperfectly translucent or opaque, and is easily recognised by its dodecahedral crystals.

Gar'netberry, a common name given to the fruit of the red currant (*Ribes rubrum*). See CURRANT.

Gar'nett, Rev. Richard, a distinguished philologist, born at Otley, Wharfedale, July 25, 1789. His literary and scholarly bias led him to quit a business life and join the Church. In 1815 he became a curate at Blackburn, in 1821 priest-vicar in Lichfield Cathedral, in 1836 vicar of Chebsey near Stafford, and in 1838 assistant-keeper of printed books in the British Museum. He contributed frequently to periodicals, and died at London, September 27, 1850. G. united vast learning, a keen scientific faculty, and a singular gift of luminous expression. His *Philological Essays* (Edinb. 1859), a selection from his contributions to journals, are a treasury of fresh research, lucid statement, and penetrating speculation. His essay on the Celtic tongues is an especially valuable contribution to the science of language. In the mellow humour and racy anecdotage with which he occasionally flavours his erudition he somewhat recalls the great scholars of the 16th c. See the memoir by his son prefixed to his *Philological Essays* (Lond. 1859).

Gar'nish (Fr. *garnir*, 'to furnish') was formerly a kind of tax which gaolers levied on their prisoners. It is now prohibited by statute.

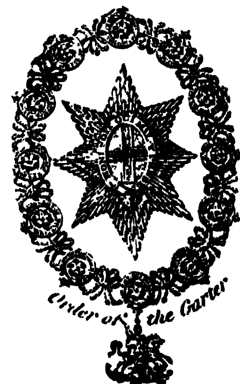
Gar'nished, in heraldry, is applied to an ornament set on a charge.

Garonne' (Gael. *garbh* and Cymr. *garw*, 'rough,' seen in *Garry*, *Yarrow*, &c., 'the rough stream,' Lat. *Garumna*), a river of the S. of France, which rises in the Val d'Aran in the Spanish Pyrenees, flows N.E. as far as Toulouse, and afterwards N.W. through Gascony and Guyenne, passes by Bordeaux across sandy and marshy tracts, and widens into the estuary of the Gironde (q. v.), which opens on the Bay of Biscay. Its total length is 350 miles, and it is navigable for about 250 miles. It is enlarged in its course by thirty-two affluents, eight of which are navigable. From the Pyrenees it receives the Salat, Ariege, Gers; from the highlands of the Cevennes and of the Auvergne region, the Tarn, Lot, and Dordogne, the last of which is its largest tributary. The G. waters a beautiful valley, rich in corn and wine. The Canal du Midi connects it with the Mediterranean. It may be called the boundary between the Celtic and the Basque population of France.

Garonne, Haute, a department in the S. of France, on the borders of Spain. Area, 2429 sq. miles; pop. (1872) 479,362. The S., covered by spurs of the Pyrenees, is a picturesque region of snowy peaks, lakes, and beautiful valleys, containing fine pastures and dense forests, and watered by wild torrents. The N. consists of low hills and plains rich in corn, fruit, and maize, and, especially around Toulouse, famous for their vines. The chief river is the G. (q. v.). Lead, copper, iron, zinc are found, and white and finely-variegated marble is quarried. The leading manufactures are cottons, woollens, and pottery. The exports consist mostly of grain, wine, wood, horses, and cattle. G. is traversed by the Boulogne-à-Cette Railway, and by the Canal du Midi. The chief town is Toulouse. G. belongs to the old Euskarian land; its inhabitants are mostly Basque (Iberian), a non-Gallic, probably a non-Aryan race.

Garr'ick, David, was the son of a half-pay captain in the army, and born at Hereford, 20th February 1716. In 1735 he was for some months a pupil of Samuel Johnson at Edial, near Lichfield, and accompanied his master to London. After trying various professions, including law, he chose the stage, and in 1741, under the assumed name of Lyddal, he appeared at Ipswich as 'Aboan' in *Oroonoko*. From the provinces he proceeded to London, and at Goodman's Fields, October 19, 1741, as 'Richard III.' achieved so pronounced a success, that after that day his career was one long triumph. He was as popular in comedy as in tragedy. As a playwright he produced a number of pieces which are now forgotten, but which 'took' at the time and his managerial career culminated (1773) in his becoming sole director of Drury Lane Theatre. In 1749 he married the celebrated dancer Mdlle. Violette, who brought him £6000, proved a good wife, and survived till 1822. His extraordinary versatility has recently been doubted, and it is questioned whether as a Shakespearian actor he was not surpassed by Edmund Kean; but his fame certainly surpasses that of any other English actor. In 1769 he conducted the Shakespeare Jubilee at Stratford-upon-Avon. He died 20th January 1779, leaving a large fortune, estimated at about £150,000. G. had many good qualities in private life, but was vain, jealous, and morbidly sensitive to ridicule. See P. Fitzgerald's *Life of G.* (1868), and for a clever sketch of his character, Goldsmith's *Retaliation*.

Garr'ison (Fr. *garnison*, from *garnir*, derived from a Teutonic source: comp. Old Eng. *warnian*, 'to take care,' 'to defend'), a body of men placed in a fortress or fortified town, to defend it against the enemy or to keep the inhabitants in subjection. The name is also given to a place where troops are placed in barracks.



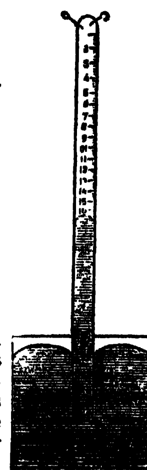
Garrison, William Lloyd, the leader of the American abolitionists, was born in Newburyport, Massachusetts, U.S., December 12, 1804. From being a compositor, he became editor of the *Free Press* in his native town, and in 1828 went to Bennington, Vermont, to conduct a paper in which he espoused temperance and emancipation. In 1829 he united with B. Lundy in editing the *Genius of Universal Emancipation*, in Baltimore. In this paper he advocated *immediate* emancipation 'in the name of God and humanity.' He opposed colonisation, and for an article on the domestic slave trade was convicted for libel and imprisoned until his fine was paid by a friend. In January 1831 his real life-work began in the founding of the *Liberator* in Boston. He made this paper an organ for temperance, women's suffrage, and the abolition of capital punishment. In January 1832 he organised the New England, and in 1833 the American, Anti-Slavery Society. From 1843 till 1865 he was president of the latter. Great agitation both N. and S. attended his movements. In October 1835 he was assailed by a mob led on by men of property and standing in Boston. He was led through the streets by a rope around his body, and was with difficulty rescued and lodged in gaol for safety. G. denounced the Union as a 'covenant with death and an agreement with hell.' In the darkest time his 'clarion voice' was oft and long heard in behalf of freedom; and his fiery invectives against Church and State in league with slavery kindled a passionate enthusiasm in generous breasts, not only in America, but even in England. His cause being finally crowned with success, he closed the agitation in 1865, the *Liberator* expiring at the end of that year. G. visited England in 1832, 1840, 1846, and in 1867, on the last occasion receiving much honour. His works consist of *Thoughts on African Colonisation* (1832); *Sonnets and other Poems* (1843); *Selections from his Writings and Speeches* (1852).

Garr'ot (*Clangula*), a genus of *Anatidæ* or Ducks (q. v.), in which the bill is somewhat shorter than the head. To it belong the golden-eyed duck or G. (*C. glaucion*), the harlequin duck (*C. histrionica*), and the spirit or buffel-headed duck (*C. albeola*). The first-mentioned species visits Britain in winter, and appears to breed in the Arctic regions. The nests are commonly constructed in holes—a fact of which the Laplanders are said to take advantage by inducing the birds to lay their eggs in boxes, and thus securing them. The harlequin duck derives its name from its curiously-marked and mottled plumage; the buffel-head is a familiar N. American species of G.

Garrott'ing (Span. *garrote*, 'a stick' or 'cudgel'). By 24 and 25 Vict. c. 96, any one using personal violence to another in an attempt to rob him is liable to penal servitude for life, and by c. 100 an attempt to choke is made an aggravation, rendering the offender liable to being whipped in addition to the other punishment.

Garr'ow (Garo) Hills, a district of Assam, British India, S. of the Brahmaputra, bounded N. by Kamrup, S. by Mymensing. Area, 3390 sq. miles; pop. (1872) about 80,000. This tract was first brought under direct British management in 1866, and in 1872 the intervention of an armed force was required. The hills produce valuable timber and cotton. Elephants are numerous. The headquarters of the Deputy Commissioner are at Tura. The G. people, of whom there are about 13,000 in Bengal proper, and 14,000 in the rest of Assam, are a very primitive race. They are divided into villages, with headmen and priests, and into clans; descent and inheritance of property is traced through the female line. Human sacrifice was formerly practised. Slaves are numerous (Dalton's *Ethnology of Bengal*, Calcutta, 1872).

Gar'ter, Order of the, a military order of knighthood founded by Edward III. in 1344. It consisted at first of twenty-six members, of whom the king was head, but in 1786 the number was raised to thirty-two. The chief sign of the order is a garter of blue velvet, edged with gold, and inscribed *Honi soit qui mal y pense* ('Evil be to him who evil thinks'). The mantle is of blue velvet lined with white. The order is also known as the Order of St. George, that saint being regarded as its principal patron. *Garter king-at-arms*, next to the Earl-marshal the chief officer of the Heralds' College, is herald to the O. of the G., and principal king-at-arms in England. His office was instituted by Henry V. in 1420. In 1874 there were forty-nine knights, none below an earl in rank. The Bishop of Winchester is prelate, and the Bishop of Oxford is the dean of the order. See Ashmole's *History of the O. of the G.* (1672).



Garth, Sir Samuel, a distinguished physician and wit, was born of a good family at Bolam, Yorkshire, in the latter half of the 17th c. He studied at Cambridge, and settled in 1692 in London, where he gained a very wide practice, and was famed as a conversationalist among the brilliant Whig society of the time. In 1700 he procured interment for the body of Dryden in Westminster Abbey, and delivered the poet's funeral oration. As chosen poet of the Kitcat Club, he produced numerous verses, praising Whig beauties and decrying the Tories, and in reward for his political constancy and fervour was knighted by George I. in 1714, and appointed physician in ordinary to the king. He died at London, January 18, 1718. Pope, who was always grateful to G. for having 'inflamed him with early praise,' and who very often alludes to him, said that 'if there ever was a good Christian without knowing himself to be so, it was Dr. G.' The chief work of G. is his *Dispensary* (1699), a mock-heroic attack on the physicians and apothecaries who were opposed to supplying medicine gratis to the poor. It was at first very popular, but its personalities are now without interest, and its satire somewhat blunted. He also wrote a poem on the house of Clare (1715), and took part in a translation of Ovid's *Metamorphoses*, to which Gay, Congreve, and Pope contributed. See Johnson's *Lives of the Poets*, and Spence's *Anecdotes.*

Gärt'ner, Friedrich von, a German architect, born at Koblenz in 1792. He is chiefly notable for his efforts to revive mediæval architecture. Among the positions held by G., were those of Professor of Architecture (since 1820), director of the Academy of Arts, and head Government surveyor in Munich. He died 21st April 1847. G. is best known by his *Ansichten der am meisten erhaltenen Monumente Siciliens* (1819), an account of the chief monuments preserved in Italy; but specimens of his work as an architect are found in Munich and other cities of Germany. The Romanesque style appears in all his buildings.

Gartsherr'ie, a village of Lanarkshire, and a station on the Caledonian Railway, 6½ miles E. by N. of Glasgow. It has extensive ironworks and collieries, which formed the original lease of the Baird (q. v.) family. Pop. (1871) 1915.

Gas Anal'ysis. The analysis of a gaseous mixture is a problem of frequent occurrence to the chemist, and it is therefore of importance that he should possess accurate methods for its accomplishment. The existence of substances similar to air in physical properties, but altogether different from it in chemical composition, was scarcely considered before the discovery of hydrogen by Cavendish and of oxygen by Priestley; and consequently previous to these discoveries G. A. was not needed. The first method of G. A. was suggested and employed by Priestley. He had discovered that nitric oxide unites with oxygen, and that after the mixture of the two gases had been made, a contraction in volume took place. Priestley showed that from this contraction an estimate might be made of the quantity of oxygen present in air. The apparatus for observing this contraction, and, therefore, for judging of the purity of the air, or the amount of oxygen it contained, was called a *eudiometer* (*eudios*, 'fine,' and *metron*, 'a measure'). Priestley's method, however, was inaccurate, as were others subsequently introduced. The analysis of a gas was first made an accurate and simple operation by Bunsen of Heidelberg more than thirty years ago. The apparatus employed in the analysis of gases has since been modified by Williamson and Russell, Regnault and Reiset, Frankland and Ward; but Bunsen's method still remains in practice. The limits of this article prevent us from entering into a discussion of the various apparatus; we can only point out the principle of the method now in use in the analysis of gases. Gases may be divided (for the consideration of their analysis) into two groups:—(1) Those which can be absorbed, and therefore removed from a gaseous mixture by the action of solid or liquid substances; (2) those which cannot be so absorbed. In analysing a mixture containing gases of the first group, a certain quantity is first introduced into the eudiometer tube. (This consists of a glass tube graduated from above downwards, and having platinum wires sealed to its upper part, which nearly touch one another and permit an electric spark to pass between them.) In introducing the gaseous mixture under examination into this tube, it is first filled with mercury and inverted in a vessel of mercury. A sufficient quantity of gas is then made to bubble up into it, and thus to displace the mercury. Careful observations are then made (1) of the volume of the gas; (2) of its temperature (or, what comes to the same thing, if the gas has remained long enough in the tube, of the temperature of the room); (3) of the height of the column of mercury in the tube above the level of the mercury in the outer vessel; (4) of the height of the barometer. The difference between the fourth and third observation gives the pressure of the gas. A knowledge of the pressure and the temperature is of the greatest importance, because the volume of a gas alters considerably if either of these change. A certain volume, then, of the gas having been introduced into the tube, and its temperature and pressure noted, the absorbent is introduced either in the solid or liquid condition, as the case may be; and when no further contraction is observed, the volume of the residual gas is measured and its temperature and pressure observed as before. In ascertaining the results of the analysis, it is necessary to compare the volumes before and after absorption under the same conditions of temperature and pressure. The temperature and pressure at which gases are compared with one another are 0° C. and 760 millimetres. A calculation is therefore necessary to arrive at the volume which the gases *would* occupy if measured under these conditions. This is accomplished by means of the formula

Eudiometer Tube.

$$V' = V \times \frac{B}{760} \times \frac{273}{273 + t}$$

In which

V′ = The volume at 0° C. and 760.
V = The observed volume.
B = The height of the barometer in millimetres.
t = The observed temperature.

The volume which a gas occupies at 0° C. and 760 millimetres is called its normal volume. To arrive at the normal volume of the absorbed gas, the normal volume of the gas after absorption is subtracted from the normal volume of the mixture before absorption. The gases which can be determined by absorption are as follows:—

(1) Hydrochloric acid, hydrobromic acid, hydriodic acid. These are absorbed in sulphate of sodium.

(2) Hydrosulphuric acid (sulphuretted hydrogen), sulphurous acid, carbonic acid. These are absorbed by caustic potash, but not by sulphate of sodium.

(3) Oxygen, nitric oxide, carbonic oxide, olefiant gas. These are absorbed neither by sulphate of sodium nor by caustic potash. Oxygen is absorbed by a solution of pyrogallic acid and caustic potash. Nitric oxide is determined by the addition of a small quantity of oxygen to convert it into nitrous acid, and then the latter is absorbed by caustic potash. Carbonic oxide is absorbed by a solution of cuprous chloride, olefiant gas by fuming sulphuric acid.

The gases of the second group (*i.e.*, those which cannot be determined by absorption) are estimated indirectly. They consist of nitrogen, hydrogen, and gaseous hydrocarbons (marsh gas, ethane, &c.). Nitrogen is determined by removing all the other gases and measuring the residual volume; hydrogen, by adding to the mixture excess of oxygen, closing the tube with the thumb, and exploding by means of an electric spark. Two-thirds of the contraction which occurs represents the volume of hydrogen. The gaseous hydrocarbons are estimated in much the same manner, but after the contraction which follows the explosion has been observed, the carbonic acid is absorbed by caustic potash, and the contraction again observed. Two-thirds of the first contraction represents the volume of the hydrogen, the whole of the second that of the carbonic acid which has been formed by the oxidation of the carbon. The weight of carbon and hydrogen is easily ascertained from a knowledge of the facts that 22·33 cubic centimetres of the latter at 0° C. and 760 millimetres weigh 0·002 grammes, and that the same volume of the former contains 0·012 grammes of carbon.

Gas, Lighting by. Gas, the popular name of coal-gas, was first turned to useful account for purposes of illumination in 1792 by Mr. W. Murdoch, who lighted his premises at Redruth, in Cornwall, with it. Twelve years later he applied it to the illumination of Messrs. Boulton & Watt's factory at Soho, Birmingham, and other works were soon thereafter similarly lighted. In 1810 the London and Westminster Gaslight Company was incorporated by Act of Parliament, and in 1813 gas superseded the use of oil in certain London thoroughfares. From remote times gas had been observed as a natural product issuing from rents in the earth's crust, and for some years before Mr. Murdoch's success its production from coal formed a common laboratory experiment. Whenever the utility of gas for artificial lighting was demonstrated, it ceased to be regarded as a scientific curiosity, and its manufacture soon developed into an important branch of industry. Since that period the use of gas has gradually spread throughout the civilised world, lightening labour, stimulating research, creating new branches of industry, and otherwise conferring inestimable benefits on mankind. It has been calculated, on trustworthy data, that in 1874 not less than 7,300,000 tons of coal were used in the United Kingdom in gasmaking.

When coal is subjected to destructive distillation in retorts or close vessels, various volatile products are expelled, and coke remains as residue. The products evolved are permanent gaseous compounds of hydrogen, carbon, oxygen, nitrogen, and sulphur mixed with vapours condensable into liquids and solids. Part of the permanent gases consists of impurities, and these, together with the condensable products, are removed as far as practicable in the subsequent processes of manufacture. The purified gas contains marsh gas, hydrogen, carbonic oxide, olefiant gas, various hydrocarbons, and nitrogen, with traces of other impurities. In the course of manufacture, tar and volatile oils, ammonia compounds, sulphuretted hydrogen, carbonic acid, and bisulphide of carbon are eliminated. The illuminating power of gas is chiefly due to olefiant gas and other heavy hydrocarbons, which all burn with a bright flame. Marsh gas, hydrogen, and carbonic oxide compose the great bulk of gas, and have more value as heat-producers than light-givers; nitrogen is incombustible and useless, and is regarded as an impurity. The relative proportions of the whole volatilised products are governed by the temperature and duration of the destructive distillation. A low temperature favours the production of a large proportion of condensable hydrocarbon vapours, while a high heat decomposes the luminous gases, and evolves many of little practical value. It is a matter, therefore, of the utmost importance to employ a temperature that will yield the highest proportion of the more valuable and less injurious heavy hydrocarbons.

Highly bituminous coal is best adapted for gasmaking. Cannel and Scotch parrot coal yield good gas with little coke, and English caking coals much gas of an inferior quality with superior coke. A ton of the latter yields on an average 10,000 cubic feet of gas, and the cannel coal of Wigan and Lesmahago, yield respectively 9500 and 11,300 cubic feet per ton. The richest coal for gasmaking yet discovered in the United Kingdom is the cannel of Boghead near Bathgate. It yields 15,000 cubic feet of gas per ton, of an illuminating power equivalent to from 35 to 40 standard candles.

The apparatus used in the manufacture of gas consists essentially of a series of retorts which communicate with a hydraulic main, in which part of the tar is deposited; the cooling apparatus, where the condensation of the liquids is completed; various purifiers for removing gaseous impurities; and a gas-holder for storing the purified gas.

The *retorts* are usually D-shaped or oval tubes of fireclay, 7 to 10 feet long, 12 inches high, and 18 inches wide. They are placed horizontally in groups of five or six in a furnace. The open end of each retort has a mouthpiece of cast iron, with a lid which can be tightly screwed down and luted after the charge of coal (about 1½ cwt.) is introduced. From the neck a cast-iron stand-pipe rises up perpendicularly, and with a curve dips down into the large horizontal cylinder of cast iron called the *hydraulic main*. The main is kept half filled with tar, into which the ends of the *dip-pipes* enter, the return of the gas to the retorts when opened for recharging being thus effectually prevented. The gas, charged with impurities, escapes from the retorts by the stand-pipes and dip-pipes to the hydraulic main, and under the reduced temperature a considerable portion of its vapours is condensed. Large quantities of the tar and ammoniacal products liquefy in the main, whence they pass by an overflow pipe into the tar well, to be subsequently withdrawn. The hot gas then passes into the *condenser*, to be freed of all the residual vaporous liquids. The condensed vapours flow into a cistern, and the gas leaves the condenser greatly reduced in temperature. The noxious gases sulphuretted hydrogen, ammonia, and carbonic acid still remain, and their elimination must be effected as thoroughly as possible. A portion of them is got rid of by the use of the *lime purifier*, between which and the condenser an *exhauster* or pumping engine is commonly placed, which relieves the retorts from internal pressure, and causes a continuous flow of the gas from the hydraulic main through the whole apparatus to the gas-holder. Slaked lime, either in the form of a powder or milk of lime is the most effective agent in removing the impurities still in the gas. The *dry*-lime purifier is composed of a rectangular iron vessel containing sieves or perforated shelves spread over with fresh-slaked lime. The gas is led in at the bottom of the purifier, and in passing through the layers of lime it leaves behind the sulphuretted hydrogen and carbonic acid and part of the ammonia. Three such purifiers are used in succession. The quantity of lime required depends upon the amount of impurities in the gas. One thousand cubic feet of gas, with 5 per cent. of impurities, requires 15 lbs. of lime.

In the *wet*-lime purifier the gas is brought into contact with milk of lime agitated by a stirrer. Spent gas lime, which possesses a most fetid odour, is, after drying, partly used for luting the retorts and partly sold for manure. A mixture of hydrated oxide of iron and sawdust has been found to be a very efficient substitute for lime, but it does not remove the carbonic acid, and consequently entails the subsequent use of lime. The remaining ammonia is removed by leading the gas from the dry-lime purifier to the bottom of an apparatus called a *scrubber*, which is filled with small coke, furze, or other material. Water percolates through it, and dissolves out the ammonia as the gas ascends. The thoroughness of the purifying processes may be tested as follows:—If sulphuretted hydrogen be present, it will blacken a test paper dipped in acetate of lead; ammonia will impart a brown colour to a turmeric test paper slightly moistened; and a turbidity in lime-water will ensue if the gas passed through it contain carbonic acid. The purified gas then passes to the *station-meter*, which measures and registers the quantity and rate of production, and thence it makes its exit to the *gas-holder* to be stored for use. A gas-holder consists of a large cylindrical tank of wrought iron, inverted into a tank of masonry or brick-work containing water. The inverted tank is confined in its position by cast-iron columns, provided with guiding rods, up and down which the tank moves freely. Sometimes it is suspended from the columns by chains with heavy counterbalancing weights; but the use of an exhauster renders this unnecessary, as the pressure of gas flowing in is always sufficient to raise the tank, and occasionally it has to be weighted to drive the gas through the street mains. The outlet and inlet pipes for the gas rise above the level of the water. Evaporation is to a great extent retarded by a layer of coal oil, which soon collects. Telescopic gas-holders—two or three tanks sliding into each other—are in use in some large works. The amount of gas to be consumed within a certain time regulates the size of the tank.

The gas is distributed for consumption through large cast-iron conduit-pipes or *mains*, with smaller ramifications, called *service pipes*, leading to and connected with the *gas-fittings* of the dwelling-house or place where the gas is to be consumed. The gas-fittings—small tubes of tin or pipe-metal—serve to convey the gas to the burner. Between the gas-holder and the mains a *governor*, resembling a small gas-holder, is placed to regulate the flow of the gas and maintain a uniform pressure. It is so contrived that the orifice of the inlet pipe is contracted if the pressure of gas in the gas-holder exceed that in the mains, and *vice versa*. Governors are also introduced into mains to correct variations arising from different levels. *Regulators*, acting on the same principle, are placed near meters or on burners to control the delivery pressure to $\frac{8}{10}$ths of a inch column of water, representing $\frac{1}{30}$th of a lb. per square inch. Gas practically increases in pressure $\frac{1}{10}$th of an inch of water for every 10 feet of altitude on account of atmospheric pressure diminishing.

Gas meters are self-acting machines for measuring the quantity of gas burned by a consumer. In the early days of gas-lighting meters were unknown, and the consumer was charged according to the number and size of his burners, and the duration of

lighting. The first gas meter was made about 1815 by Mr. Samuel Clegg, a name inseparably associated with the early improvements in gas machinery. Two kind of meters are now used, *wet* and *dry*. The wet meter consists of an iron cylindrical case, more than half filled with water, enclosing a smaller cylinder or drum closed at the ends and rotating on a horizontal axis. The drum is divided by four curved radii into five chambers, four around a central one. Each of the four outer chambers communicates by one small aperture with the space between the two cylinders leading to the outlet pipe, and by another with the axial chamber into which the gas is led by a pipe bent above the level of the water. These apertures are opened and closed in succession as the drum revolves through the water. The gas on passing into the central chamber escapes into one of the compartments, and by expansive action on the upper side and on the water causes the drum to rotate. Each of the chambers is in turn subjected to this process, the rotation being thereby maintained; and while the gas is passing into one chamber, it is escaping from another and making its way to the burners. The drum has a known capacity, and the number of cubic feet passed through it in one revolution is indicated on separate dials marking from 1 to 10,000 cubic feet by means of an arrangement of toothed wheels driven by the axle of the drum. The wet meter has several defects. The flow of gas is apt to cease if the water be not maintained at its proper level; aqueous vapour may condense in the gas-pipes, and either choke them or cause unsteadiness in the flame; and an exposed meter is liable to derangement from frost. To remedy these and other defects the dry meter has been invented. In it there are two or more measuring chambers from which the gas is displaced by the piston-like action of metal discs. By each backward and forward motion, controlled by nicely-contrived valves, a certain constant quantity of gas is discharged, and its registration is effected by suitable clockwork connected by levers with the discs. The dry meter is not so durable as the wet meter, and faulty working is not so easily detected. Various forms of it are gradually being introduced by English gas companies and on the Continent, and in the United States they are extensively adopted.

The Sale of Gas Act (1859) regulates the construction of meters, and provides for their public inspection, and sealing if found correct. The adoption of the Act, however, is optional. The economical consumption of gas is in a great measure promoted by the use of proper *gas-burners*. Those chiefly used are the union jet or fishtail, bat's-wing, Argand, and its various modifications. The nipple of the former is pierced obliquely with two holes meeting at the top and producing a flat flame; the bat's-wing has a fine slit and gives a flame of the form implied. These two are best suited for burning cannel gas issuing at a pressure of five to six tenths of an inch of water. In the Argand burner the gas issues from a number of minute holes on the upper surface of a hollow ring, and burns with a circular flame. The Bude burner is a concentric series of Argand rings. Glass chimneys are used with the Argand burners in order to effect the complete combustion of the gas, which to be burned to best advantage should not exceed 18 to 19 candle power.

As the value of gas depends upon its illuminating power, it is of the utmost importance to estimate it. This is effected, among other methods, by the use of a Photometer (q. v.). By it a comparison is made between the light of a gas flame consuming at the rate of 5 cubic feet per hour, and a sperm candle, one-sixth of 1 lb. weight, burning 120 grains per hour, called a *standard candle*. The comparative cost of different lighting materials giving the same amount of light has been shown by experiment to be as follows:—Spermaceti candles, 6s. 8d., paraffin candle, 3s. 10d.; tallow candles, 2s. 8d.; sperm oil, 1s. 10d.; and gas, 4½d.

In regard to wholesomeness gas contrasts favourably with other artificial lights, as well as in its safety. Unlike candles and lamps, it is not carried about, it emits no sparks, and dispenses with 'snuffing' or trimming. Its peculiar smell quickly permeates the air and leads to the detection of leakage. Gas is explosive only when mixed with air in the proportions of from 3 to 9 of air to 1 of gas. Gas of a highly illuminating quality may be obtained from substances other than coal, as peat, wood, resin, oil, and petroleum. None of these, however, have as yet entered into serious commercial competition with coal for the manufacture of gas.

Gascoigne', George, an Elizabethan poet, son of Sir John G. of Cardigan, Bedfordshire, was born about 1525. He was educated at Trinity College, Cambridge, studied law at Gray's Inn, was imprisoned in 1548 on a charge of dicing, and after a course of dissipation, served as a soldier in Holland under William of Orange. He returned to England in 1573, and in 1575 recited verses before Queen Elizabeth at Kenilworth. Henceforth he lived by his pen, producing numerous pieces, mostly of a satirical cast, until his death at Stamford in 1577. G. was a prolific and versatile writer. His play *The Supposes*, translated from Ariosto, is the earliest English prose comedy; his *Dan Bartholemew* is the first English imitation of the Italian mock-heroic poetry; his *Jeronini* is the forerunner of the euphuistic prose tales of Greene and Lyly; and his *Steel Glas* (1576), one of the earliest long English satires. G. possessed uncommon literary energy. His verse is remarkably clear and abounds in rough mirthful vigour and pathetic personal retrospects. Minto compares G. to Byron in his life and the style of his writing. A complete edition of his works by W. C. Hazlitt has been issued in the 'Roxburghe Library.' See Minto's *English Poets* and Skeat's *Specimens of English Literature*.

Gascoigne, Sir William, an English judge, who has obtained a place in history, was born at Gawthorp, Yorkshire, about 1350. On the accession of Henry IV. he was made a Justice of Common Pleas, and in 1401 Chief Justice of the King's Bench. His courageous vindication of law as something higher than royal mandate was exemplified in his refusal to pass sentence of death upon Archbishop Scroop as a traitor. Still more famous is the incident immortalised by Shakespeare when he ordered Prince Henry to be committed to prison for striking him on the bench. G. died 17th December 1413.

Gasconade', a river rising in Missouri, U.S., and flowing N.E. to the Missouri, which it joins 36 miles below Jefferson city, after a course of 250 miles. It gives name to a village, and to a county rich in yellow pine and other timber.

Gasconnade, in French, is a boastful or extravagant statement, the Gascons having been proverbial for braggadocio. The word *Gascon* is also used as synonymous with boaster, and a verb *gasconner*, to boast, has been formed.

Gas'cony (Fr. *Gascogne*, Lat. *Vasconia*, 'the land of the *Basques*,' *Vascons* or *Gascons*), an old province of the S. of France, which lay between the Atlantic, Pyrenees, and Garonne. It included the present departments of Hautes Pyrénées, Landes, and Gers, and parts of Haute-Garonne, Tarn-et-Garonne, and Lot-et-Garonne. It was united with Aquitaine, passed to Henry II. of England in 1152 on his marriage with Eleanor, the divorced wife of Louis VII., and was not joined to the French monarchy until 1453.

Gas'-Engine is an engine of the same general structure as the ordinary steam-engine, but differs in obtaining its motive power from the explosion of a mixture of inflammable gas and air. As early as 1799 Lebon, a French artisan, had constructed and patented such a machine. The inflammable mixture, introduced alternately on each side of the piston, was fired by an electric spark. It was found to work well and effectively, but coal gas not having been at that time introduced for illuminating purposes, the expense of preparing the mixture rendered the scheme a practical failure. Lenoir's engine, patented in 1860, was very much a reproduction of Lebon's; while the chief points of difference in Hugon's machine, constructed about the same time, consisted in firing the mixture by a gas jet and in introducing a little water, which, converted into steam by the great heat, lessened the violence of the action. Very different in action, and much more economical in the consumption of its fuel than any of its predecessors, is the invention of Otto and Langen of Köln, exhibited at Paris in 1867. The gaseous mixture, introduced beneath and fired by a permanent gas jet, shoots up the heavy piston to the top of the vertical cylinder. A partial vacuum ensues and the piston descends, urged down by its own weight and the atmospheric pressure. A heavy fly-wheel equalises the motion as far as possible, and maintains the action during the moments when the piston is ineffective.

Gas'es are fluids which ultimately fill the vessel in which they are contained. This power of indefinite expansion dis-

tinguishes them at once from liquids, and renders it impossible for them to be contained in open vessels. When a gas is kept in a closed vessel, it exerts upon the walls of the vessel an outward pressure, an explanation of which is readily found upon the hypothesis, first advanced by Daniel Bernoulli, and now universally accepted, that a gas consists of a crowd of minute particles, shooting about in all directions with generally great velocities. The pressure, then, obviously depends upon the number of impacts which take place over unit surface in unit time. Hence, if the number of particles in the given enclosed space be increased—in other words, if the density be made greater—the pressure must also increase; and experiment proves that this increase of pressure follows the very simple numerical law that *at constant temperature the pressure is proportional to the density*. This law was first enunciated by Robert Boyle in 1668 under the form: the volume of a portion of a gas varies inversely as the pressure. Another and very suggestive statement proposed by Rankine is, that any portion of gaseous matter exerts the same pressure against the sides of a vessel as if the other portions had not been there; and this, as shown by Dalton, whether these portions be of the same gas or not.

It is known from experiment that matter, whether it be solid, liquid, or gaseous, is raised in temperature when heat is applied, provided that during the operation there is no change in condition; and further, that this rise of temperature is *generally* accompanied by an increase of volume. In the case of G., a very simple numerical law, discovered by Charles in 1787, holds. It is, that under constant pressure, and for a given rise of temperature, the volume of a gas expands by a fraction of itself, which is the same for all G. Thus, a gas at 0° C. expands by $\frac{1}{273}$ of its volume for a rise of 1°; and a gas at 1° C. expands by $\frac{1}{274}$ of its volume for a further rise of 1°, and so on. Or, if we take a gas of 273 cubic inches at 0° C., and under a given pressure, its volume at 1° C. will be 274; at 2°, 275; at 10°, 283; at 100°, 373, &c. This hints at an absolute zero of temperature 273° below zero Centigrade, a result fully corroborated by other thermo-dynamic relations, and permits us to enunciate Charles's law in the much simpler form, that *at constant pressure the volume of a gas is proportional to its absolute temperature.* Boyle's and Charles's laws may now be combined in the formula $pv = Ct$, where p is the pressure, v the volume, t the absolute temperature, and C a constant depending upon the particular gas used. No gas accurately fulfils this law; and when the gas is near its point of liquefaction, the deviations from it are considerable. The G. which are difficult of liquefaction—such as hydrogen, oxygen, nitrogen, &c.—however, very nearly fulfil it, and more nearly the higher the temperature and greater the volume. When a gas is permitted to expand of itself, its temperature falls, since part of its thermal energy is transformed into mechanical work to effect the expansion; and when a gas is suddenly condensed, an evolution of heat is the consequence, which of course ultimately tends to raise the temperature of the gas. According to the Kinetic Theory given above, which regards a gas as a crowd of molecules moving in all directions with various velocities, the absolute temperature of a gas is proportional to the arithmetic mean of the squares of the individual velocities. The square root of this mean is called the velocity of mean square, and by it we compare different gaseous systems. Calling the velocity V, the equation $pv = Ct$ may be written [illegible], where ρ is the density, and a a constant equal to [illegible] for the ideal perfect gas. This equation may be put in the form [illegible], where m is the mass of an individual molecule, and n the number of molecules in unit volume. For another gas, [illegible]; hence, if the pressure is the same for both, [illegible]. If their temperatures are equal, evidently [illegible]; and hence (dividing the one equation by the other) follows Avogadro's law, that *two G. at the same temperature and pressure have the same number of molecules in unit volume.* A direct consequence of this is [illegible], or the densities of two G. at the same temperature and pressure are proportional to the masses of their individual molecules; a law first given by Gay-Lussac in the form that the densities of G. are proportional to their atomic weights.

The majority of G. can be condensed to the liquid form, and in general there is a distinct transition stage from the gas form to the liquid. Dr Andrews of Belfast has shown, however, in the case of carbonic acid, and probably of all G., that if the condensation be effected by pressure while the gas is kept at a temperature above a certain critical value, it is impossible to fix the moment of transition or to tell when the substance ceases to be gas and begins to be liquid. Under EVAPORATION, the chief phenomena attending the transformation of liquids into G. are noticed. In certain circumstances G. may condense at once into the solid state, as exemplified by the sublimation of sulphur and the formation of hoar-frost. The resistance which G. present to solids passing through them is of great importance in the practice of Gunnery (q. v.). It increases with the velocity; but except for moderate velocities, when it may be taken as proportional to the *square*, the resistance is related to the velocity according to a complex and only approximately determinable law. In the phenomenon of Winds (q. v.), we have the relative motion of large portions of the same gaseous material, a motion which also experiences resistance. In this case, however, the resistance is probably due chiefly to the mutual diffusion of contiguous portions. Under the headings HEAT, LIGHT, SOUND, &c., other properties of G. will be noticed. See also MOLECULAR THEORY. In Clerk Maxwell's *Theory of Heat* and Balfour Stewart's *Treatise on Heat*, the Kinetic Theory is discussed with fulness and lucidity.

Gas'kell, Elizabeth Cleghorn, an English novelist, born in 1822. She became the wife of the Rev. William G., a Unitarian minister at Manchester, and died November 12, 1865. Her leading works are *Mary Barton* (1848), a touching tale of factory life in Manchester, *The Moorland Cottage* (1850), *Ruth* (1853), *North and South* (1855), *Lizzie Leigh, Cranford, Sylvia's Lovers* (1863), *Cousin Phyllis*, and a *Life of Charlotte Brontë* (1857). Her novels give faithful and graphic pictures of artisan life and forcible delineations of character, besides showing tender human sympathy, quiet humour, and fine descriptive power.

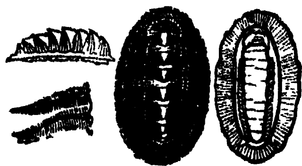
Gas-Lighting in Railway Trains. Gas has been applied to the lighting of railway carriages, but to a very limited extent. Several plans have been suggested, but the fact that gas-light in trains has not been generally adopted is evidence that no method yet devised meets the exigencies of the case. These are, that little room be occupied by the apparatus, that each carriage be lighted independently of the others, and that the light be as brilliant, as cheap, and as certain under all circumstances as oil on long journeys. Gas, under the ordinary pressure, has been used for many years on the Metropolitan Underground Railway. The gas-holder is replenished at the end of a double journey. This plan, it is obvious, is quite impracticable in journeys of some hours' duration. The difficulty to be overcome, before the general adoption of gas-lighting, is to reduce gas, stored under a pressure of 10 or 15 atmospheres, to a pressure of $\frac{5}{8}$ths of an inch column of water, and to maintain it thereat under all circumstances during consumption.

Gasom'eter. See GAS, LIGHTING BY.

Gaspé Basin, a prosperous village in the province of Quebec, on the beautiful Bay of Gaspé, which stretches about 20 miles inland from the Gulf of St. Lawrence. It is the chief port of entry under the free port system, has new wharves and stores, and bids fair to become the capital of the fertile district of Gaspé. There are valuable whale and cod fisheries, and petroleum is obtained in the neighbourhood. Pop. 700.

Gassen'di, Pierre, a French philosopher and astronomer, was born at Champtercier (Basses Alpes), January 22, 1592. He studied at Aix, where in 1616 he was chosen Professor of Philosophy and Theology. Relinquishing this post in 1623, he obtained a benefice at Digne, where he wrote his *Exercitationes Paradoxicæ adversus Aristotelem* (Grenoble, 1624), a work in which he asserted his utter disbelief in the prevailing dogma that the Church and the scholastic philosophy were inseparable. After a visit to Paris in 1624, and to Holland in 1628, he became Professor of Mathematics in the College Royal de France at Paris, where he died, 24th October 1655. He adopted the philosophy of Epicurus; and though his views were in direct antagonism to those of Descartes, he had for that philosopher a deep admiration, and even a warm friendship, which, however, ceased for a time after the publication of his *Disquisitio Metaphysica adversus Cartesium* (Par. 1644). His greatest work is his *De Vita, Moribus et Placitis Epicuri* (Lyon, 1649), of which his *Syntagma Epicuri* forms a

part. As an astronomer and mathematician G. did not display much original talent, but he strongly favoured the study of physical science. He was the first to observe the transit of Mercury predicted by Kepler, and wrote biographies of Tycho Brahé, Copernicus, Puerbach, and Regiomontanus (which form together a history of the early progress of astronomy), a treatise on *Parhelia* (Par. 1630), and a descriptive catalogue of astronomical observations taken between 1618 and 1655. G. was a steady and courageous friend of men like Kepler, Galileo, and Hobbes. His collected works were published by Montmort and Sorbière at Lyon in 1658, and by Averrani at Florence in 1728. See Bugerel's *Vie de G.* (Par. 1737).



Gasse'rian Gang'lion is a swelling on one of the roots of the fifth cranial nerve, situated on the upper part of the petrous portion of the temporal bone. It gives off three branches—(1) the ophthalmic, which enters the orbit; (2) the superior maxillary, for the upper jaw; and (3) the inferior maxillary, for the external ear, the tongue, the lower teeth, and the muscles of mastication. The G. G. is on the sensory root of the nerve. Its special functions are unknown.

Gass'ner, Johann Joseph, an 'exorcist' of the last century, was born at Bratz, in the Tyrol, August 28, 1727. Entering the Catholic Church, he became priest at Klösherbe, in the diocese of Coire, and in a short time acquired a reputation for curing with a mere prayer or command persons in fits or otherwise 'possessed of devils.' For a time he had crowds of believers, and although some prelates opposed, others, including the Bishop of Ratisbon, supported him; and even yet, in spite of efforts made to convict him of imposture, there are many who consider him to have possessed some equivalent to the 'mesmerism' or 'psychic force' of the present day. He died Dean of Berndorf, 4th April 1779.

Gas-Tar. See TAR.

Gasteromycetes, one of the six orders into which the *Fungi* (q. v.) are divided, of which the Puffball (q. v.) is an example.

Gasterop'oda (Gr. 'belly-footed'), a large class of Higher or Cephalous *Mollusca*, distinguished generally by having a *shell*, commonly *univalve* or composed of one piece (as seen in the whelks), or which exists in one family (that of the *Chitonidæ*) as a *multivalve* structure, *i.e.*, composed of more than two pieces. In no case is the shell of G. *bivalve*, or composed of two pieces, as in *Lamellibranchiata* (q. v.). A shell may be wanting, however, in many G., as in the slugs, sea-lemons (*Doris*), sea-hares (*Aplysia*), &c. The locomotion of the G. is performed, as seen in the snail or whelk, by a broad ventral 'foot,' from which the class derives its name. Occasionally, as in the *Heteropoda*, this 'foot' may be modified from the more typical form to a flattened fin-like organ. The foot is generally divisible into a *propodium*, *mesopodium*, and *metapodium*, these divisions being the front, middle, and posterior portions of the organ; and the metapo[illegible] develops a horny or limy plate [illegible] *operculum* [illegible] to close the shell when the anima[illegible] withdrawn into [illegible]. The head of the G. has *ten*[illegible] and [illegible] and the mouth contains a *tongue* or *odontophore*. Organs of [illegible] are also developed in the form of *otoliths* or ear-sacs. The digestive system comprehends a *stomach, intestine, liver*, and *salivary glands*. The *heart* consists of an auricle and ventricle, and is [illegible] *temic*, in that it serves only to pro[illegible] pure blood [illegible] system. Breathing is carried on by gills or [illegible] simply by the walls of the *mantle* [illegible] being the general investment or s[illegible] the [illegible] other *Mollusca*, secretes and en[illegible] ture in the G. exists essentially in [illegible] seen in its simplest form in the limpet, [illegible] shell of the whelks and other G. is formed [illegible] ing rolled upon itself. The G. shell may [illegible] *Planorbis*, where the whorls of the bod[illegible]

Gasteropod.

it may be *turreted*, *trochoid*, or more commonly *turbinated*. A central axis or *columella* is seen in G. shells, this axis having the embryonic or first-formed shell at its apex, so as to constitute a kind of *nucleus*. The mouth aperture may be unindented (*holostomatous shells*, *e.g.*, snail), or indented by a groove for the passage of a breathing-siphon (*e.g.*, whelk), when the shell is said to be *siphonostomatous*. The *nervous system* consists of three chief ganglia, one in the head (*cephalic* or *cerebral*), a second in the foot (*pedal*), and a third in the neighbourhood of the heart and gills (*branchial* or *parieto-splanchnic*). The sexes may be distinct or united in the same individual, and the young Gasteropod (whether possessing a shell or not when adult) is invariably provided with a small shell. The G. are *classified* in two chief divisions, the *Branchio-G.*, or those breathing by means of gills, and the *Pulmo-G.*, or those breathing by lung-sacs. The chief families of the first division are the *Muricidæ* and *Buccinidæ* (whelks), *Cypræidæ* (cowries), *Conidæ* (cone-shells), *Littorinidæ* (periwinkles), *Patellidæ* (limpets), *Chitonidæ* (chitons), *Aplysidæ* (sea-hares), *Doridæ* (sea-lemons), &c. In the Pulmo-G. the snails (*Helicidæ*), slugs (*Limacidæ*), and other families are included.

Fossil G.—These *Mollusca* appear to be first represented as fossils in the Upper Cambrian rocks, and they hold a place in all the stratified formations down to the present day, when they attain perhaps the maximum of their development.

Gasteros'teus. See STICKLEBACK.

Gastral'gia, or **Stomach Colic,** is a severe pain in the stomach frequently arising from slight causes. In some cases it is invariably produced by certain articles of diet, such as an egg; in others by irregularities in diet; and in others again every sort of diet produces it, so that each meal is followed by severe pain. Women are more subject to G. than men, but cases occur of this disease among men otherwise robust and healthy. The seizure is sudden, and the pain is most severe round or above the umbilicus. G. may continue from a few moments to a few hours, and it subsides almost as rapidly as it appears, leaving, however, a soreness. G. is generally accompanied by sickness, vomiting, flatulence, and diarrhœa. In G. the pulse is natural; there is no fever; and the pain is relieved by pressure, features which distinguish it from Enteritis (q. v.). Treatment:—Hot fomentations, mustard poultices, and friction. When the bowels are confined, an aperient should be given, followed by opiates or diffusible stimulants, as ether, chlorodyne, &c.

Gas'tric Juice. This is the juice secreted by various small glands in the mucous membrane of the Stomach (q. v.). When obtained without mixture with saliva, it is a clear, colourless, slightly viscid, acid fluid, which under the microscope shows only a few cells derived from the glands. As obtained from man, it has the following chemical composition in 1000 parts:—Water, 994·4, solids, 5·60—the solids consisting of (*a*) *organic matter*, a peculiar ferment termed *Pepsin* (q. v.), 3·19, and (*b*) *inorganic matter*, consisting of chloride of sodium, 1·46, chloride of potassium, 0·55, chloride of calcium, 0·06, phosphates of magnesia, lime, and iron, 0·12, and a slight trace of free acid, which some chemists have determined to be hydrochloric, while others [illegible] The active principle of the G. J. is pepsin [illegible] the albuminous [illegible] Peptones (q. v.). The [illegible] the stimulus [illegible] with the inner surface of the [illegible]

Gas[illegible]

Achilles. The other two muscles of the group are the *soleus* and *plantaris.* See LEG.

Gastrolo'bium, a genus of Leguminous plants embracing many species peculiar to Australia. They are chiefly shrubs with yellow flowers, and are very poisonous to cattle, large numbers of which die yearly by eating the foliage. The most fatal species are *G. bilobum* and *G. spinosum.* Several species are grown in British greenhouses.

Gastros'tomy (Gr. *gastēr*, 'the belly or stomach,' and *stoma*, 'the mouth'), an operation which has been performed to relieve the patient from starvation by making an incision through the abdomen into the stomach for the purpose of introducing food directly into the stomach. By such means life may be prolonged for a short time, and the patient may be sustained until the obstruction is removed, as in cases of stricture of the gullet.

Gastrot'omy (Gr. *gastēr*, 'the belly,' and *tomē*, 'an incision'), an incision into the cavity of the Abdomen (q. v.) for the purpose of removing some foreign body, diseased tissue, or the fœtus *in utero*, in which latter case the operation is called Cæsarean Operation (q. v.). G. is very frequently had recourse to in modern surgery for the purpose of removing diseased ovaries, and such operations are designated Ovariotomy (q. v.).

Gates, Horatio, a general of the American revolution, born in England in 1728. He entered the British army, served with General Braddock in 1755, and was wounded at Fort Duquesne, now Pittsburg. At the close of the war he settled in Virginia. On the breaking out of the War of Independence in 1775, he was made adjutant-general, and accompanied Washington to Cambridge (Massachusetts). He received command of the troops N. of Albany, and in October 1777 compelled General Burgoyne and his whole army to surrender at Saratoga. Defeated at Camden, 16th August 1780, by Lord Cornwallis, he was then superseded by General Greene, but was restored in 1782. In 1790 he freed all his slaves, and retired to New York, where he died, April 10, 1806.

Gates, Stealing or Injuring. Under 24 and 25 Vict. c. 97, persons maliciously damaging any fence, wall, stile, or gate are punishable by a fine of £5 above the amount of the injury done. A second offence is punishable by imprisonment with hard labour. See MALICIOUS INJURIES TO PROPERTY; FENCES, LAW REGARDING.

Gates'head, a town of England in the county of Durham, on the steep southern bank of the Tyne, opposite Newcastle, of which it practically forms a part, and with which it is connected by three bridges. It has a large parish church with a lofty tower, besides some fifty other established and dissenting churches; a handsome townhall (1869); a charitable hospital (St. Edmund's), restored by James I., and since known by his name; the Albert Memorial Reformatory; a mechanics' institute; and an ably-conducted dispensary, since an outbreak of cholera in 1831–32. The houses are mainly brick-built, and in the older parts of the town are squalid and rickety. There are extensive ironworks, foundries, brickfields, and special manufactures of anchors, chain-cables, [illegible] wire, chemicals, soap, glass, and tiles. The quarries [illegible] 'Newcastle grindstones' are at G. Fell. Pop. [illegible] which sends one member to Parliament, be-[illegible] 1826, having been previously (since [illegible] officer under the bishops-[illegible] Roman relics (coins, &c.) found here [illegible] that G. was an outwork of the [illegible] was partly [illegible] in a great [illegible]

[illegible] of the Greek and Roman cities [illegible] and in the middle ages large [illegible] entrances to castles, religious houses, [illegible] was [illegible] [illegible] by [illegible] [illegible] gateways [illegible] arches [illegible] for [illegible] [illegible]

Gath (Heb. 'a wine-press') was one of the five royal cities of the Philistines (Josh. xiii. 3). It was captured by David when he came to the throne, but does not seem to have remained long in the hands of the Israelites (1 Chr. xviii. 1; *cf.* 1 Kings ii. 39). It was captured by Hazael, King of Syria, in the reign of Jehoash of Israel, 856 B.C. (2 Kings xii. 17), and by Uzziah, King of Judah, who dismantled it (2 Chr. xxvi. 6). In the time of Amos it was in ruins (vi. 2), and after that is no more heard of, except in a proverb (Mic. i. 10).

Gat'ineau, the name of a river and lake of Canada, in the province of Quebec. The lake lies about 150 miles W. of Grand Lake, in lat. 48° N., and is one of a series out of which rises the river, which flows S.S.W. and then S., expands into lakelets at various points, receives the Jean de Terre, and enters the Ottawa opposite the city of Ottawa, after a course of nearly 300 miles.

Gat'ling, Richard Jordan, an American inventor, was born in N. Carolina, U.S., 12th September 1818. At an early age he was anticipated by Ericsson in the discovery of screw propulsion, but his ingenuity was successfully shown in devising a machine for sowing wheat in drills. G. studied medicine at Ohio and Cincinnati, 1847–49, and subsequently engaged in railway and real estate speculations. In 1850 he invented a double-acting hemp-breaker, and in 1861–62 elaborated his masterpiece, a mitrailleuse, or repeating machine gun. At the first trial of the 'G. gun,' in 1862, it fired 200 shots per minute. It has since been adopted in the United States, as well as by several European Governments, for use with troops, and for the flank defence of fortifications.

Gatschi'na, a town of Russia, on Lake Ishora, 30 miles S.S.W. of St. Petersburg. It is the seat of a beautiful royal palace (1770), the favourite residence of Paul I., which has 600 rooms, and is encircled by splendid gardens. G. has porcelain industries, and includes among its buildings a horticultural school, and a school for foundlings. Pop. 8890.

Gau, a German word meaning generally a district, as in *gaugraf*, 'count of a district,' and more specially an old political division of Germany, which embraced several villages, and was governed by several grafs. The division was abolished in the 12th c., but the name survives in *Thurgau, Aargau, Rheingau,* &c.

Gauge, a word of various applications, signifying usually an instrument for measuring dimensions, capacity, pressure, &c. Thus we have the *button G.* for finding the dimensions of buttons; the *rain G.* for measuring the rainfall; the *steam G.* for registering the pressure of steam in a boiler; the *tide G.* for determining the height of the tide; the *wind G.* for indicating the velocity of the wind (see ANEMOMETER), &c. The railway G. is the distance between the rails of a railway; hence the *narrow G.* (4 feet 8½ inches) and the *broad G.* (7 feet).

Gauge of Railways, Law Regarding. The Act 9 and 10 Vict. c. 57 renders it unlawful to make a railway for the conveyance of passengers on any other gauge than one of 4 feet 8½ inches in Great Britain, unless the whole railway is S. of the Great Western; but railways already made on a different gauge may be so maintained: 5 feet 3 inches is the Irish gauge under the Act. The penalty for making a railway contrary to the Act is £10 per mile for every day the railway is in use.

Gau'ger (Old Fr. *gauger*, 'to measure,' probably through *galger*, from Lat. *qualificare*, 'to ascertain qualities of a thing'), an excise officer who *gauges* or measures casks of excisable liquor. A G. may not, under a penalty of forfeiting his office, traffic in excisable goods, and if he accept a bribe, is liable to a penalty of £500, and is rendered incapable of holding any Government post.

Gau'ging, in mensuration, is the measurement of the capacity of a vessel of any kind, and is of great importance in the collection of the revenue. In most instances the determination is only approximate, the vessel being taken as some simple surface of revolution, such as a spheroid or paraboloid or simply a cylinder, to which it may bear some approximate resemblance.

Gaul. See FRANCE.

Gault, the lowest member of the Upper Cretaceous formation, intermediate in position between the Lower and Upper

Greensands. It consists of a stiff compact blue clay, often used for brickmaking, and contains fossils (chiefly *Lamellibranchiata* and *Gasteropoda*) in a beautiful state of preservation. G. is developed principally at Folkestone and in Cambridgeshire. Contemporaneous rocks are found in the compact sandstones of the Blackdown Hills of Devon, in the *Lower* Pläner of N. Germany, in the schistose beds near the Swiss canton of Glarus, and in the corresponding formations of France.

Gaulthe'ria, a genus of shrubby plants belonging to the order *Ericaceæ* (q. v.). The species, which are numerous, are found in various parts of the globe, but are most abundant in America. *G. procumbens*, commonly called 'winter-green' in the United States, contains a peculiar aromatic volatile oil, which separates by distillation, and is used in medicine and perfumery under the name of 'winter-green oil.' Its leaves are astringent, and have been used as a substitute for tea; hence it has also been called 'mountain tea.' Its berries supply food during early winter to many animals, hence the plant has received the names partridge-berry, deer-berry, box-berry, &c. *G. Shallon* is a shrubby plant about 2 feet high, found in the N.W. of America. It has been introduced into Britain for a considerable time, where it flourishes in pleasure-grounds and open woods, and yearly bears abundance of berries much relished by game. The fruit makes excellent tarts. *G. hispida* of New Zealand produces white berries which are eaten.

Gaunt, John of, Duke of Lancaster, third son of Edward III., was born at Ghent—whence his name—in 1339, and married his cousin Blanche, daughter of the Duke of Lancaster, in 1359, succeeding to his father-in-law's estates in 1362. After fighting in Spain, he led an English army into France in 1372, but met no resistance, and retreated to Bordeaux with only a remnant of his troops. During Edward III.'s latter years he took a large share in the government, and rendered himself very unpopular by his overbearing insolence towards the commons, and by striving as the leader of the barons against the national party to undo the reforms of the Good Parliament. Being anxious to sieze the wealth of the great churchmen, he for a time supported Wiclif, but afterwards withdrew his favour from the reformer. The peasant revolt of 1381 forced him to fly to Scotland, whence he shortly returned to England. Claiming the throne of Castile through his marriage with a daughter of Pedro the Cruel, he invaded Spain, and in 1388 married his daughter to the Prince of the Asturias. He afterwards tried fruitlessly to rule Guienne. G. died in 1399. He was the patron of Chaucer, and is the knight of *The Boke of the Duchesse*. He is the 'time-honoured G.' of Shakespeare's *Richard II.*, where he delivers the famous panegyric on England. See Green's *Short History of the English People* (Lond. 1875).

Gaunt'lett, Dr. H. J. G., musician, was born at Wellington, Salop, in 1805, and practised as a lawyer in London. He became organist of St. Olave's, Southwark, in 1827, was made Doctor in Music in 1842, and died 21st February 1876. He was a vigorous writer, a good organist, a prolific composer of hymn-tunes and anthems, and a strenuous promoter of congregational psalmody.

Gaur, or **Gour,** the ancient Hindu capital of Bengal, of which only ruins now remain, situated in Maldah district, on the left bank of the Ganges, about 180 miles N. of Calcutta. The original Sanskrit name was Lakshmanawati or Lucknouti. Its history has been traced back to the 7th c. A.D. In 1202 it was taken by the Mohammedans, and remained the seat of government under the Afghan dynasty until the triumph of the Mogul Akbar in 1574. About this latter date the main stream of the Ganges deserted its old bed, and the city was depopulated by a pestilence. The area now covered by ruins was estimated by Rennell to extend over 30 sq. miles, and the population could hardly have been less than one million souls. The whole has relapsed into jungle, the most renowned shooting-ground for tigers in Bengal. A few mosques and gateways still stand, in an indifferent state of repair, but the majority of the buildings have been pulled down, and the materials used in the towns for fift[illegible] miles round. The most celebrated monument is a circul[illegible] minar or tower, 81 feet high and 21 feet in diameter, which is[illegible] scribed in Fergusson's *Indian Architecture*. There are se[illegible] large tanks, with masonry banks, containing good drinking [illegible] one of which is nearly one mile long and half a mile wid[illegible]

Gaur, or **Gour** (*Bibos gaurus*), a variety of oxen (*Bovidæ*) found in small herds in S. Bahar, and other parts of Hindustan. The horns are depressed at the base; the shoulders high and prominent; the spinous processes of the dorsal vertebræ very largely developed. The general colour is a deep brown, the females being of lighter hue than the males. The average height is about 6 feet at the shoulders. A distinctive mark of the G. consists in the fore-legs being white from the knees downwards. Attempts to domesticate the G. have not been very successful. The flesh is tender and palatable, and the hides furnish strong leather.

Gauss, Karl Friedrich, a mathematician of the highest order, was born at Brunswick, 30th April 1777. In 1795 he went to the University of Göttingen, where in 1807 he became professor and director of the Observatory. Before this date he had earned a wide reputation by his *Disquisitiones Arithmeticæ* (Leips. 1801), and by his elaborate calculations of the elements of Ceres and Pallas. His *Theoria Motus Corporum Cœlestium* (Hamburg, 1809; Ger. by Haase, 1865) displays, like all his works, a marvellous combination of the greatest power of theoretical generalisation with the utmost possible practical application. In this work appears his discussion of the methods of Least Squares (q. v.), introduced by D'Alembert, and now of immense practical importance. In 1811 he calculated with singular accuracy and detail the parabolic course of the famous comet of that year. For a considerable time after this geodetic measurements engaged his attention; and during 1821-24, at the instance of the Hanoverian Government, he measured the meridian arc between Göttingen and Altona, introducing into his system of triangulation many highly original and important improvements. His principles are explained in his *Theoria Combinationis Observationum Erroribus Minimis Obnoxiæ* (Gött. 1821-23), with *Supplementum* (1826). The arrival of Weber at Göttingen in 1831 directed him to the study of the magnetism of the earth. He invented most refined and delicate instruments for recording magnetic variations and declinations; and his energy was rewarded by the formation of observatories in different localities for determining these magnetic elements. The results were published at Göttingen (6 vols. 1837-43). In 1840 his *Atlas des Erdmagnetismus* (3 vols. Leips.) was given to the world, containing the whole theory, which has undergone little extension since then. In it he introduces the function now known as the *Potential* (q. v.), proving by its means, notwithstanding, the great generality and complicacy which necessarily existed in such a subject, many important theorems, such as the impossibility of there being more than *two* magnetic poles on the earth's surface. Dioptrics, equations, series, the rotation of the earth, and other subjects in pure and mixed mathematics successively engaged his attention. His last great work w[illegible] *[illegible]ntersuchungen über Gegenstände der höhern Geodäsie* (Gött. [illegible]-47). G. died at Göttingen, February 23, 1855. Until [illegible] papers, which are scattered through the various [illegible]mati-cal publications of the day, are collecte[illegible] to fully realise how much he has done to [illegible] has influenced its progress. His co[illegible] has been published by Peters (4 vols. [illegible] A. von Humboldt, by Bruhns [illegible] *seines Lebens und Wirkens* by [illegible]

Gau'tier, Théophile, [illegible] writers, was born at Ta[illegible] was educated at the C[illegible] and was in early [illegible] and the old Fren[illegible] volume of poems[illegible] disciples during [illegible] cal schools[illegible] 1833 he [illegible] *Maupin*[illegible] book [illegible] Bal[illegible] F[illegible]

ancient Egypt), *Voyage en Russie*, *Voyage en Espagne* (1843), *Théâtre* (comedies and brief humorous pieces), *Les Grotesques* (1844), notices of Villon, St. Amant, and other old French poets, *Nouvelles* (1845), *Romans et Contes*, *Émaux et Camées* (1852), *Constantinople* (1854), *La Capitaine Fracassé* (1863), *La Belle Jenny* (1865), *Peau de Tigre* (1865), *Spirite* (1866), *Tableau de Siége* (1872), &c. As a poet G. is only surpassed in French literature by one or two names, and for beauty of prose style is unexcelled by any of his countrymen. In his poetry, which has been well described as 'the faultless expression of a worship for things formally beautiful,' the French language appears endowed with new flexibility, richness, and metrical variety. See the autobiographic sketch in G.'s *Portraits Contemporains*, his *Romantisme*, and C. Baudelaire's *L'Art Romantique*.

Gauze, a thin delicate texture woven of very fine hard-spun fibre. It was originally made of silk alone, and previous to the development of the cotton trade its manufacture constituted an important industry in the W. of Scotland, of which some traces still survive. Silk G. is much used by millers in flour sifting. The name is said to be derived from *Gaza* in Palestine, where G. was first manufactured.

Gavar'ni, the well-known pseudonym of Sulpice Guillaume Paul Chevalier, a French caricaturist, who was born in Paris in 1801. Beginning life as a mechanical draughtsman, he early discovered a genius for burlesque pencilling. He first published sketches of the valley of Gavarni in the Pyrenees; hence his *nom de plume*. About 1835 he began to contribute regularly to *Charivari* and other comic journals the wonderful series of ever-varying social and character sketches, instinct with artful originality and scathing cynicism, which earned for him the name of the 'arch-fiend of caricature.' Among his best-known works are *Les Enfants Terribles*, *Les Parents Terribles*, *Les Rêves*, *Comme l'on dîne à Paris*, *Les Fourberies de Femmes*, and *Impressions de Ménage*. He successfully illustrated many popular works, as Eugene Sue's *Wandering Jew* and Balzac's *Diable à Paris*. G. died at Auteuil, 23d November 1866. A selection from his sketches was published in Paris, 1845, in 4 vols. 8vo, with notes by Théophile Gautier, and 2 vols. subsequently under the title of *Perles et Parures* (1850).

Gavazz'i, Alessandro, a celebrated anti-Papal agitator, was born at Bologna in 1809. Admitted in 1825 into the order of Barnabites, he showed great natural powers of eloquence, and became Professor of Rhetoric in Naples. In 1846 he threw himself heartily into the liberal policy of the 'reforming Pope,' Pius IX., and was appointed chaplain-general of the Roman patriotic legion sent to the aid of the Milanese. The Pope, however, becoming reactionary, withdrew the legion, whereupon G. abandoned his allegiance, and joined in the agitation which ended in the flight of the Pope and the establishment of a republic. After the failure of the struggle with France, G. left Italy for England and since 1851 has figured chiefly as a lecturer against the Papacy. His add[illegible] have been [illegible] some places, *e.g.*, [illegible] revisited [illegible] the Two [illegible] was again active [illegible] speaking [illegible] Protestantism [illegible] ad, and [illegible] but not [illegible]

[illegible] In some of the [illegible] of England [illegible] by immemorial custom [illegible] gavel- [illegible] an equal share in the real [illegible] of a [illegible] custom is ancient, but [illegible] or [illegible]

[illegible] often [illegible] distinctive [illegible] form [illegible] nearly [illegible] in form [illegible] nostrils [illegible] The [illegible] hed [illegible] G. [illegible]

chiefly of fishes. Fossil G. occur in Eocene rocks in the S.W. of England and elsewhere.

Gavina'na, a village of N. Italy, province of Lucca, in the romantic valley of the Lima, 35 miles N.W. of Florence, is notable as the scene of the final overthrow of the army of republican Florence under the chivalric Ferruccio, at the hands of the imperialist Philibert, Prince of Orange, in 1530.

Gavot, Gavotte', a dance-tune somewhat resembling the country-dance, which was in fashion principally from 1670 to 1760. On it was founded an instrumental piece or movement much employed in the 'suites' of Bach and Handel. It was originally a dance of the *Gavotes*, *i.e.*, the people of Gap in France.

Gay, John, an English poet, was born near Barnstaple in 1688. He was sent to London as a silk-weaver, but in 1712 became secretary to the Duchess of Monmouth, having the year before published *Rural Sports*, a poem dedicated to Pope, with whom he formed a warm friendship, and at whose suggestion he wrote *The Shepherd's Week* (1714), a burlesque on the eclogues of Philips. It contains, however, some of the most natural pastoral poetry in the language, and resembles Spenser's *Shepherd's Calendar* in its English colour. Through the influence of the Tories G. accompanied the Earl of Clarendon as secretary to Hanover, whence he returned in two months to England. In 1715 his burlesque *What d'ye Call It* was well received, but his next piece, the farce *Three Weeks after Marriage*, entirely failed. In 1726 his *Fables* appeared, and in 1727 his *Beggar's Opera*, the idea of which was suggested by Swift, was received with enthusiasm, and ran for sixty-three nights. Its chief characters, 'Macheath,' 'Polly,' and 'Lucy,' were a delightful change from conventional heroes and heroines, and its humorous mimicry of the Italian opera, then a fashionable novelty in England, its sparkling wit, touching simplicity, charming songs, and delightful music, combined to ensure it a brilliant popularity, the memory of which is not yet forgotten. G. died December 4, 1732, and was buried in Westminster Abbey. He was a natural and graceful poet. In his *Beggar's Opera*, 'he extracted,' says Hazlitt, 'an essence of refinement from the dregs of human life.' His *Fables* (best ed. Owen, Lond. 1856), though somewhat tedious, are easy and fluent; his *Trivia, or the Art of Walking the Streets of London*, gives interesting glimpses into the life of his times; but his fame rests on his lyrics, which have a flowing melody and pathetic sweetness peculiar to G. An edition of his poetical works in 3 vols. appeared at London in 1797, and another in 2 vols. 1806.

Gay, Marie-Françoise-Sophie, a French authoress, whose maiden name was Nichault de Lavalette, born at Paris, July 1, 1776, married M. Gay, and wrote many romances and several dramatic pieces. Her salon was a famous resort of authors and artists. She died at Paris, March 5, 1852. Among her works are *Laure d'Estelle* (1802), *Anatole* (1815), *Le Moqueur Amoureux* (1830), *Scènes de Jeune Age* (1833), *La Duchesse de Châteauroux* (1834), *Les Salons Célèbres* (1837), *Le Mari Confident* (1849). See Gautier's *Notices Contemporaines*. —**Delphine G.**, afterwards **Madame de Girardin**, a French poetess and novelist, daughter of the above, was born at Aix-la-Chapelle, January 26, 1804. When only seventeen she wrote a prize poem, which, though unsuccessful, was read publicly before the French Academy. Shortly afterwards she produced several poems, for which a pension was bestowed on her mother, whom she then accompanied to Rome. There she was enthusiastically received and crowned in the Capitol. On her return to Paris she became the ornament of a literary circle which included Lamartine, Balzac, Hugo, and Gautier, the last of whom describes her as a dazzling beauty. In 1831 she married the journalist Émile de Girardin, and afterwards issued several novels, which were well received. From 1836 to 1848 she contributed to her husband's paper *La Presse* her well-known *Lettres Parisiennes*—letters on literature, art, and current topics, written with charming airiness and vivacity. She died at Paris, June 29, 1855. Sainte-Beuve, Gautier, and Jules Janin have extolled her beauty, wit, and literary genius. Among her numerous works are *Essais Poétiques* (1824), *Nouveaux Essais Poétiques* ([illegible]5), *Contes d'une Vielle Fille à ses Neveux* (1832), *La Canne [illegible]. de Balzac* (1836), *Lettres Parisiennes* (1836–39), *Nouvelles* [illegible], *Marguerite* (1853). See Sainte-Beuve's *Causeries du Lundi*.

Gay'a, or **Gyah** (the name of a god), the chief town of a district of the same name, province of Bengal, British India, on the Phalgu river, about 265 miles N.W. of Calcutta, and 55 miles S. of Patna. The old town is inhabited by the priests and their followers, and the new town (called Sahibgunge) contains the official and trading population. G. is one of the most celebrated centres of pilgrimage in India, and was known even in the Buddhist period. At present it is frequented by Hindus, who come to worship the infernal deity Gaya, for the sake of the souls of their ancestors. It is estimated that 100,000 pilgrims come to G. every year; and a single Mahratta prince has been known to pay £10,000. The old town is unusually picturesque; the houses are mostly of brick and stone, with ornamented verandahs. Pop. (1872) 66,843.—The *district* of G. contains 4718 sq. miles and (1872) 1,949,750 souls. The soil is fertile, but the density of the population is excessive. The old manufactures of weaving and paper-making are dying out. In the E. and N. of G. district are situated the most ancient stone memorials of Buddhism in all India.

Ga'yal (*Bos Gavæus*), a variety of oxen found in a wild state in Central Asia and N. India, and in a domesticated state in Bengal. The form of the body resembles that of the buffalo; and although the body is not humped, the front portion of the back is very prominent. The head is broad and flat, the muzzle prominent, and the horns of small size, and directed outwards and slightly upwards. The colour is a dark brown. The gayals are domesticated for the sake of the flesh and hides, and the milk is said to be very rich and plentiful.

Gay-Lussac', Joseph Louis, a French chemist and physicist, was born December 6, 1778, at St. Leonard (Haute-Vienne). In 1794 he went to Paris, and in 1797 entered the École Polytechnique, where he became Professor of Chemistry in 1809. In 1804 he performed his celebrated balloon ascents, the first with Biot, and the second alone. Most of his early investigations in specific gravities, specific heats, gaseous laws, the decomposing action of the voltaic pile, &c., appear in his *Recherches Physico-chimiques* (2 vols. Par. 1811). In 1816 he began the *Annales de Chimie et de Physique* with Arago; and in this and the *Comptes Rendus* many of his numerous memoirs are published. He is specially famous in connection with iodine, cyanogen (which he discovered), bleaching chlorides, alcohols, ethers, alkalies, the manufacture of sulphuric acid, &c. In 1832 he obtained the chair of general chemistry at the Jardin des Plantes, in 1839 was made a peer of France, and died at Paris May 9, 1850. G.'s chief works, besides those already mentioned, are his *Cours de Physique* (edited by Grosselin, Par. 1827), and his *Leçons de Chimie* (collected by Marmet, 2 vols. Par. 1828). See the *Éloge de Gay-Lussac* by Arago, read at the *Académie des Sciences*, 20th December 1852.

Ga'za (Gr., Heb. *Azzah*, Deut. ii. 23) was one of the most ancient towns in Palestine and the capital of the Philistines, by whom it was taken from the *Avim*, the earliest inhabitants of whom there is any notice (Deut. ii. 23; Josh. xiii. 2, 3). G. formed the limit on the S.W. of the territories of the ancient Canaanites (Gen. x. 19) and of Joshua's conquests (Josh. x. 41). It fell to the lot of the men of Judah, who indeed took it, but were unable to keep it (Judges i. 18, 19). Alexander the Great besieged G. after taking Tyre, and only took it after a five years' siege. Captured and razed to the ground (about B.C. 96) by Alexander Jannæus, it was rebuilt by Gabinius, governor of Syria (Jos. *Ants.* xiii. 13, 3, and xiv. 5, 3). It was again destroyed by the Jews about A.D. 65 (*Bell. Jud.* ii. 18, 1), but soon recovered. The secret of its importance and prosperity was its situation; it lay in the line of communication between Egypt and the whole region of Syria. In Christian times G. remained a stronghold of idolatry. It was taken by the Mohammedans in 634, and since that time has gradually declined. The modern town (*Ghuzzeh*) has about 15,000 inhabitants.

Gaza, Theodorus, one of the Renaissance scholars, was born about 1405 at Thessalonica, whence, after its capture by the Turks in 1430, he removed to Italy. He became Professor of Greek at Ferrara, was patronised by Pope Nicholas V, Cardinal Bessarion, and King Alfonso of Naples, and finally obtained a benefice in S. Italy, where he died in 1478. He translated Aristotle's *History of Animals*, the *History of* [illegible] by Theophrastus, and other Greek works into Latin; [illegible] treatise *De Mensibus Atticis*, a Greek grammar, *Introductivæ Grammatices* in 4 books, and various literary epistles. Scaliger said he envied only three scholars—G., Poliziano, and Mirandola.

Gaze. In heraldry, a beast of the chase is ***at gaze*** when it looks towards the spectator.

Gazelle (Arab. *gazal*, 'a wild goat'), the name of a well-known genus of Antelopes (q. v.), more especially applied to the *Gazella Dorcas* of Arabia and N. Africa—a small animal of a light-fawn colour on the back, which deepens into a darker tint on the sides, and passes into pure white on the abdomen. The face is marked with a dark-brown stripe passing from each eye to the angle of the mouth, and by a white streak extending between the horns and the muzzle. The hinder quarters have also white markings. The horns are lyre-shaped and of moderate size, and taper to a point. The females are hornless, and the *crumen* or tear-bag is distinctly developed below the eyes. The eyes of these graceful creatures are large and lustrous, and have long been celebrated in Eastern poetry. The gazelles are found in large herds, and sometimes act against their enemies the *Carnivora* with much courage and boldness. An allied species, regarded by some naturalists as a mere variety, is the Ariel G. (*G. Ariel* or *Arabica*) of Syria and Arabia, which differs from the preceding species chiefly in the darker tints of its hair. Its average height is 21 inches at the shoulder. In Asia several characteristic species are found.

Gazelle.

Gazette'. This name is especially applied in England and in Scotland to the official newspaper of each country in which government and legal notices are given to the public. The *London G.* is published on Tuesdays and Fridays, and the *Edinburgh G.* on the same days. It seems to be held that publication in the G. of notice of dissolution of partnership is not alone sufficient to free the partners from liability for debt afterwards contracted in the name of the company with any one formerly in the habit of dealing with it. With regard to parties dealing with the company for the first time, there is a difference between English and Scotch law. By the former it is doubtful whether notice in the G. is always sufficient even in a question with a stranger. By the latter it is held that persons dealing for the first time with a company ought to make previous inquiry into its circumstances, and that notice even in a provincial newspaper is effectual. But all reasonable means ought to be taken to publish the dissolution. Under the Bankruptcy Acts and some other statutes, certain notices are directed to be given in the Gazettes. The word G. is derived from the Ital. *gazzetta*, a Venetian coin about ¾d. in value, the [illegible] for permission to read the first Venetian newspaper, which appeared in the 15th c. See NEWSPAPER.

Gaz'ogene. See AERATED WATERS.

Gazons (Fr. *gazon*, 'turf'), sods used to [illegible] earthworks.

Gean, the English name for the wild cherry [illegible], the origin of the cultivated garden cherry. See [illegible]

Gear'ing, or **G**[illegible], in machinery, [illegible] parts which are [illegible] motion from one [illegible] to another (most frequently from a prime mover to [illegible]), sometimes a combination which forms part of one [illegible] employed for transmitting motion between two [illegible] of it having [illegible] velocities [illegible] cases of [illegible] other cases [illegible] used for [illegible] of, according to the arrangement of [illegible]

regarded as an oracle by the chemists of the middle ages, and is said to have written 500 works on his art. Of these, the most noted is the *Summa Perfectionis Magisterii*, published at Rome between 1490 and 1520, at Danzig in 1682. A fundamental belief of G.'s was that metals are convertible, and are all composed of sulphur, mercury, and arsenic. G.'s date is uncertain, but he lived about the end of the 8th or beginning of the 9th c. There is an English edition (Lond. 1678). A minute and complete analysis of G.'s works will be found in Höfer's *Histoire de la Chimie* (Par. 1842).

Gecko' (*Gecko*), a name given to various kinds of lizards (*Lacertilia*), included in a large family, that of the *Geckotidæ*, in the typical genus of which the toes are dilated, and furnished on their lower surfaces with expansions of the skin, enabling these animals to hold on firmly to any smooth or perpendicular surface. The tongue is flat, wide, and scarcely protrusible. The eyes are large, the eyelids short, and the pupil of linear shape, but occasionally of circular conformation. The teeth are small, compressed, and set on the inner side of the jaw; hence the creatures are *Pleurodonts*. The nails are hooked, and can be retracted at will, and the tail possesses a ridge. The G. are widely distributed in the warm parts of both hemispheres. They feed on insects, and inhabit houses, running up and down walls with great ease. The common G. (*G. verus*) is found in N. Africa, and may be known by having the back studded with large tubercles. Its colour is reddish grey, spotted with white. The house G., named 'fan-foot' from the expanded nature of the toes (*Ptyodactylus G.*), likewise occurs in the same region. Another species of G. is the fringed-tree G. (*Ptychozoon homalocephala*) of Java, known as the smooth-headed G. It is brown in colour above, with a yellowish spine-marking, and variations of darker brown wavy lines. The top of the head is similarly marked, and the under parts are a dirty white.

Gedd'es, Alexander, LL.D., a Scottish scholar of considerable note, was born at Pathhead, Enzie, Banffshire, in 1737. At the age of fourteen he was sent to the Roman Catholic Seminary of Scalan, from which he passed in 1758 to the Scots College at Paris. Returning to Scotland in priest's orders (1764), he was appointed chaplain at Traquair, where with a good library he had the best opportunity of pursuing his favourite study of Biblical Criticism. From this post he was removed (1768) and sent back to Paris by the vicar-apostolic (Bishop G. Hay), for the indiscretion of falling in love with a female relative [illegible] the Earl of Traquair. He returned to Scotland next year, and was appointed to the mission at Auchenhalrig. There he employed his leisure translating the select odes of Horace into English blank verse, in which, as well as in a number of fugitive pieces in English, Scotch, Latin, and [illegible] con-siderable poetical powers. His [illegible] liberal opinions, and particularly [illegible] parish church of Cullen, [illegible] treat-ment from Bish[illegible] finally (1779) [illegible] his diocese [illegible] degree [illegible] Univer-[illegible] and the [illegible] by [illegible] Lord Petre [illegible] n, [illegible] been the [illegible] to make a translation [illegible] Bible [illegible] Catholics. The first volume [illegible] second (and last published) [illegible] volume (and all that was published) of [illegible] in which [illegible] C. died in [illegible]. See Good's [illegible] Irving's *Lives of the Scottish Poets* [illegible] *Catholic Church in Scotland* (1869).

[illegible] sculptor, born at Antwerp, [illegible] studied in Paris and settled in Brussels [illegible] his work 'A Young Fisherman [illegible]. This composition established his [illegible] 'Victims of the Revolu-[illegible] [illegible]

severe and classical.—**Joseph G.**, brother of the preceding, born at Antwerp in 1808, was also a sculptor of reputation. Among his works are 'Godfrey of Bouillon,' 'Thierry Maertens,' 'Baldwin of Constantinople,' &c. He died at Brussels, May, 1860.—**Aloys G.**, youngest brother of Guillaume G., was a sculptor of promise, but died prematurely in 1841.

Geel, Jakob, an eminent Dutch Hellenist, was born at Amsterdam in 1789. He received a good classical education, and in 1833 was appointed head librarian at Leyden, where he died, 11th November 1862. G. is well known for his translations from German and English into Dutch, contributions to library literature, his treatises on æsthetics, such as *Gesprek op dem Drachenfels* (Leips. 1836); and above all his editions of *Theocritus* (1820), Dio Chrysostom's *Olympicus* (1840), *Excerpta Vaticana* of Polybius (1829), *Historia Critica Sophistarum* (1823), and the *Phœnissæ* (1846). His *Catalogus Codicum Manuscriptorum qui inde ab Anno 1741 Bibliothecæ Lugduni Batavorum accesserunt* (Leyd. 1852) is a learned and useful work.

Gee'long, a town in Victoria, situated on Corio Bay, a western arm of Port Philip, 45 miles S.W. of Melbourne. The trade of G., which has a good harbour, has been swallowed up by Melbourne since the establishment of railway communication between the two places; but various industries, the chief of which are woollen manufactures, meat-preserving, and tanning, are now causing the town to revive. Pop. within the municipal boundary (1871), 15,026; but including the new borough of Geelong W., and that of Newton and Chilwell, 23,000.

Gef'lo (pron. *yàvle*), the capital of the *län* of Gefleborg, Sweden, on an island at the mouth of the broad and rapid Gefle-A, 50 miles W. of Falun by railway. It is the third trading town in Sweden, has a beautiful town-house, and is overlooked by an old castle, and girt with fine gardens. There is a good harbour, and the exports include iron, timber, flax, linen, and tar, while among the manufactures are sailcloth, linen, leather, tobacco, sugar, &c. Pop. (1874) 16,787. G. is one of the oldest towns of the Swedish Norrlands, and formerly enjoyed a monopoly of trade.

Gehenn'a (Gr. from Heb. *ge-hinnom*, or *ge-ben*, or *bne, hinnom*, valley of the son or sons of Hinnom, of whom nothing further is known) was a glen which, descending from the level of the plateau on the W. of Jerusalem, and gradually deepening, ran along the W. and S. sides of the city, joining the Valley of Jehoshaphat at the S.E. corner. It was the deep, narrow gorge on the S. side which was Hinnom proper, and was also called Topheth (q. v.). The place became notorious as the scene of the rites (human sacrifices, &c.) paid to Chemosh (q. v.) and Molech (q. v.), first introduced by Solomon (1 Kings xi. 7), and restored by Ahaz and Manasseh (2 Chron. xxviii. 3, and xxxiii. 6). On the reformation by Josiah, it was polluted or rendered ceremonially unclean (2 Kings xxiii. 10), and afterwards became the lay-stall of the city, where the larvæ of insects fattened on the corruption, and fires were continually kept up to consume some of the offal. G. thus came to be used as a figure of the eternal torment of the wicked in the world to come (Isa. lxvi. 24, *cf.* Mark ix. 47, 48).

Gei'bel, Emanuel, a German poet, son of an Evangelical Reformed pastor, was born at Lübeck, October 18, 1815, studied at Bonn, and in 1838 visited Athens as tutor to a Russian prince. In 1852 he was made Professor of Æsthetics at Munich. His works include *Classische Studien* (Bonn, 1840); *Gedichte* (Berl. 1840; 58th ed. 1865); *Juniuslieder* (Stuttg. 1848; 16th ed. 1866); *Neue Gedichte* (Stuttg. 1856; 8th ed. 1865); *Brunhild* (Stuttg. 1857; 2d ed. 1861); *Sophonisbe* (2d ed. 1870), &c. [illegible] has won an extraordinary popularity, due to his love of freedom, simplicity, tender melancholy, religious vein, and exquisite [illegible], rather than to originality or imaginative power.

[illegible]i'ger, Abraham, a Jewish rabbi and well-known Orientalist, born at Frankfurt-on-the-Main, May 24, 1810, studied at Heidelberg and Bonn, in 1832 went as rabbi to Wiesbaden, in 1835 took part in editing the *Zeitschrift für Jüdische Theologie*, and in 1838 became assessor to the rabbis at Breslau. G. has been a deep student of Judaism, and has been led into fierce controversies from his endeavour to break down the exclusiveness of [illegible] Jewish religion. His works—among which are *Lehr- und [illegible] der Sprache der Mischna* (Bresl. 1845); *Urschrift und*

Uebersetzungen der Bibel in ihrer Abhängigkeit von der inneren Entwickelung des Judenthums (Bresl. 1857); and various sermons and pamphlets, &c.—show a wide and thorough knowledge of history and of Eastern languages.

Gei'jer, Erik Gustaf, a great Swedish historian and poet, born 12th January 1783, at Ransätter in Vermland. At sixteen he left the Carlstad Gymnasium for Upsala University, and at twenty wrote a celebrated prize essay on Sten Sture the elder. He graduated in 1806, and in 1810, after a year's stay in England, was appointed 'docent' in history at Upsala, but soon left for a post in the public record office in Stockholm. Together with some friends he instituted the *Götiska Forbund*, to whose journal *Iduna* he contributed many prose tracts and a few remarkable poems, some of which have been set by himself to fine music, which has greatly contributed to their popularity in Sweden. In 1812 G. published *Forsök till Psalmer*, but in 1815 he laid aside poetry and devoted himself to public lectures in history, the chair of which at Upsala became his in 1817. To regain strength exhausted in the preparation of *Svea Rikes Häfder*, of which work, however, only a single part appeared (1825), he went on a tour (1835) through Denmark and part of Germany, giving his impressions in *Minnen* (1834). In 1832 and 1836 appeared *Svenska Folkets Historia*, breaking off at the end of Christina's reign, and followed by *Sveriges Tilstand fran 1718 till 1771* (1838), *Gustav III.'s efterlemnade Papper* (1843). His lectures greatly influenced his students, who showed their warm attachment during the unsuccessful indictment for heresies in *Thorild* (1820). Failing health forced G.'s retirement in 1846; and going to Stockholm to complete his *History of the Swedish People*, he died 23d April 1847. The collected edition of his writings (13 vols. 1849-55) comprises also many papers written for periodicals and articles for *Literaturbladet*, a newspaper edited by him and expounding democratic views opposed to those he held in 1828, when, as again in 1840, he represented his university in the Swedish Parliament.

Geik'ie, Archibald, F.R.S., LL.D., a distinguished geologist, was born at Edinburgh, December 28, 1835, and educated at the High School and University of that city. In 1855 he was appointed to the geological survey of Scotland, of which he became the director in 1867, and in 1870 obtained the Murchison chair of mineralogy and geology at Edinburgh University. Besides various geological memoirs in the journals of the Geological Society and elsewhere, which entitle him to a foremost place among geologists, he has published several works bearing more or less on his special department. The principal of these are *The Story of a Boulder* (1858); *The Life of Professor Edward Forbes*, in conjunction with Professor George Wilson (1861); *The Phenomena of Glacial Drift of Scotland* (1863); *The Scenery of Scotland viewed in Connection with its Physical Geography* (1865); Jukes and G.'s *Manual of Geology* (3d ed. 1872); and *Memoir of Sir Roderick J. Murchison*, &c. (2 vols. 1872).—**James G.**, the brother of the preceding, was born at Edinburgh August 23, 1839, and was appointed to the geological survey in 1861. He is the author of *The Great Ice Age* (2d ed. 1876).

Gei'ler von Kaisersberg, Johann, an able but somewhat eccentric German preacher, was born at Schaffhausen, March 16, 1455, studied at Freiburg and Basel, became rector of Freiburg University, and in 1478 settled as a cathedral preacher in Strasburg, where he gained wide popularity, and where he died, March 10, 1510. He was a bold opponent of clerical abuses, and an earnest, vigorous preacher, using keen and homely illustrations. He did much to found useful institutions in Strasburg, and his death was regretted through Germany. His writings are now very rare. See Ammon's *G. von K.'s Leben, Lehren, und Predigten* (Erl. 1826), and Meick's *Joh. G. von K.* (3 vols. Frankf. 1829).

Ge'la, an ancient city on the river G., in the S. of Sicily, was founded by a Rhodian and Cretan colony 690 B.C. It grew rapidly, and in 582 B.C. the Geloans founded Agrigentum, which soon eclipsed G., and was for a time the most powerful state in the island. The form of government at G. was at first an oligarchy, which was subverted by the 'tyrant' Cleander, under whom (505-498 B.C.) and his brother Hippocrates (498-491 B.C.) G. flourished greatly. Gelon (q. v.), who succeeded Hippocrates by the conquest of Syracuse in 485 B.C., made G. the first city in Sicily. This position it might have kept, had not Gelon shown a preference for Syracuse, and compelled great numbers of the inhabitants to migrate thither. Under his brother Hiero G. continued to decline, but after the expulsion of Thrasybulus it again experienced a period of great prosperity (466-406 B.C.). During the Punic wars it suffered terribly. It was finally laid in ruins by Phintias, tyrant of Agrigentum, who transferred its inhabitants to a city founded by himself near the mouth of the Himera in 280 B.C., and called by his name. G. was the scene of the death and burial of the poet Æschylus, and possessed among other monuments a colossal statue of Apollo, which was carried off by the Carthaginians in 405 B.C. and sent to Tyre, where it remained till the taking of that city by Alexander the Great. *Terra Nova* occupies the site of the ancient G.

Gel'atine (from the Lat. *gelo*, 'I freeze or congeal') is a product obtained from various animal tissues, and employed in the arts and as human food according to the sources whence it is obtained and the care exercised in its preparation. When the preparation is pure and transparent in colour, yielding a solution free from smell, it is commercially known as G. and chiefly employed as food; but when brown in colour and impure in its constitution, it is called glue. Both, however, insensibly merge into each other, and excepting difference of purity they have no other distinction. The following may be regarded as the sources of the varieties of commercial G., using the term in its wide sense:—(1) The fine, clean, and fresh cuttings of sheep and ox skins, tendons, &c., from which G. for cooking and calf's-foot jelly are prepared; (2) hide-cuttings, ears, tails, &c., from tanneries, and animal refuse generally, which yield common glue; (3) bones, from which bone glue is made; and (4) swimming bladders of fish, which constitute isinglass. As the methods of preparing common G. and glue differ only in the care with which the materials are selected and the cleanliness of manipulation in the case of the former, it is to be understood that the manufacturing processes here indicated are those adopted for both. The raw materials are first treated with lime in tanks or lime-post for the purpose of cleansing them from fragments of flesh, blood, &c., the lime at the same time saponifying adherent fatty matter, and preventing putrefactive decay. Lime-water is added from day to day, and after two or three weeks the materials are removed from the tank, thoroughly washed free from lime and dried. The materials so prepared are next boiled, by which they yield up a gelatinising compound. Different degrees of temperature are required for extracting the gel[illegible] substance from different materials, and the operation [illegible] is conducted in three separate ways:—(1) By acting [illegible] by high-pressure steam, whereby a highly con[illegible] obtained with great rapidity—a process ve[illegible] in Great Britain; (2) by fractional boiling, [illegible] of material with a small proportion of water which is periodically run off, and renewed so long as a [illegible] solution continues to be obtained; (3) by boiling [illegible] with a sufficiency of [illegible] exhaust it. The last of these ways is the least satisfactory, as the first portion of G. formed by being kept at a high temperature for a prolonged period loses its power of gelatinising when cooled. The G. [illegible] tion, by whatever process obtained, is poured into flat shallow moulds, and after being hardened sufficiently, it is cut up into cakes of the size and form required. The drying operation to which it is next subjected is one of the greatest difficulty and delicacy. The cakes are placed on twine nets stretched between frames in a drying chamber, and when practicable the drying is conducted by exposure [illegible] of the [illegible]. In the application of artificial heat great care must be exercised to keep the temperature [illegible] that the G. does not become fluid by [illegible] [illegible] by irregular and unequal [illegible] [illegible] polished and [illegible] [illegible] hot water, brushing, and drying [illegible] bones are [illegible] freed from [illegible] boiling [illegible] they are treated with hydrochloric acid till they become soft and transparent [illegible] free from acid by [illegible] repeated washing with fresh water [illegible] separated by the action of steam in a closed boiler, and the solution [illegible] of ordinary glue. A [illegible]

tinising glue yielded by cartilaginous matter, and known chemically as chondrin, is prepared and used as size. Ordinary glue, if dissolved in water to which nitric or acetic acid is added, remains liquid, while it retains its adhesive properties unimpaired.

The ordinary varieties of glue have multitudinous applications for cementing or 'glueing' in joinery, &c., and as 'size' in papermaking, painting, and numerous other arts. The more pure varieties of G. are almost exclusively used in food and cookery. G. of a transparent quality is very frequently artificially coloured, and run into excessively thin plates for use as ornamental wrappings for confectionery and other fanciful purposes. Nauseous medicines are also much administered in capsules of G.

Isinglass, although the source of fish glue, being more used in its native condition than as a source of G., will be treated of under its own heading. Several substitutes for glue, as an adhesive and sizing agent, have been introduced, the most important of which are albumen glue and casein glue. The first of these is made from the gluten obtained as a bye-product of the manufacture of wheaten starch, and is largely used like ordinary glue, besides being available as a substitute for egg albumen in calico-printing and for clarifying liquids. Casein glue is obtained by dissolving the casein of milk in a strong solution of borax, and it forms a very useful glueing material for joiners and bookbinders

Gelat'inous Tiss'ues and Gelatine, the name given to various tissues found in the bodies of man and higher animals, and from which a jelly-like substance named G. is obtained by boiling. The characteristics of these tissues and of the products they afford consist in their being (1) sparingly soluble in cold water; (2) readily soluble in hot water; and (3) their free precipitation by tannic acid and chlorine-water, whilst ferrocyanide of potassium has no action upon them, this fact distinguishing them from *albuminous* compounds. The comparative chemical composition of the two forms of gelatinous compounds—*chondrin* and *gelatine*—may be seen by an inspection of the following table :—

	Gelatine.		Chondrin.	
	Mulder's analysis	Scherer's analysis	Mulder.	Scherer.
Carbon	50·4	50·8	50·0	50·7
Hydrogen	6·7	7·1	6·6	6·9
Nitrogen	18·3	18·3	14·4	14·7
Oxygen . . . } Sulphur . . . }	24·6	23·8	29·0	27·7
	100·0	100·0	100·0	100·0

Gel'derland, a province in the E. of Holland, is bounded N. by Overyssel, S. by N. Brabant, E. by Westphalia, and W. by Utrecht and the Zuider Zee. Area, 1964 sq. miles; pop. (1873) 441,088. The centre is occupied by the sandy plateau of the Veluwe (formerly *Felua*), while the S. and E. (Veluwezoom), the dryest part of Holland despite its many springs, is an undulating region covered with rich copsewood and dotted with beautiful country-seats. A tract of arid sand-dunes stretches along the Zuider Zee. The Rhine, Waal, Yssel, and Maas traverse G., and between the first two lies the fertile lowland of Betuwe (hence Roman *Batavia*), 'good meadow land,' divided into E. and W. portions by the Nieuwe Dijk. In the extreme S., between the Waal and Maas, rises the Hunenberg, clad with the Nederrijks Forest. The river valleys are highly cultivated, yielding much wheat, rye, buckwheat, hops, tobacco, &c. G. has a large trade in butter and eels. Arnhem is the capital, and other towns are Nymwegen, Zutphen, Tiel, and Harderwijk.

Gelid'ium, a genus of rose-spored seaweeds including several species, one of which is said to form the gelatinous substance of which the Chinese edible birds'-nests are made. (See NESTS.) *G. corneum* is a very common but variable species on the British coast.

Gell, Sir William, an English archæologist, was born in 1777 at Hopton, Derbyshire, and studied at Cambridge, where he graduated in 1804. In 1814 he travelled abroad with the Princess of Wales as one of her chamberlains, and appeared as a witness at her trial (1820). He subsequently settled in Italy, living chiefly in Rome and Naples, in the latter of which he died, February 4, 1836. G. is best known by writings on classical antiquities, several of which are still authorities. The chief are *Topography of Troy* (1804); *Itinerary of Greece* (1810); *Attica* (1817); *Pompeiiana, or Observations upon the Topography, Edifices, and Ornaments of Pompeii* (with J. P. Gandy, 1817-32; 3d ed. of first series, 1832); and *The Topography of Rome, and Rome and its Environs* (1834).

Gell'ert, Christian Fürchtegott, a German poet, was born at Haynichen, Saxony, July 4, 1715, and studied at Leipsic University, where, after labouring as a tutor, he became professor in 1751. He was a very successful lecturer on philosophy and rhetoric, and his writings were popular throughout Germany. G. died at Leipsic, 13th December 1769. G. was peculiarly shy and gentle, and Friedrich the Great called him 'the most rational of German professors.' His works, consisting of fables, hymns, and a few other pieces, display a pure though somewhat thin vein of poetry, glimpses of quiet humour, and deep and tender piety. They were published at Leipsic in 1769-74 (10 vols.) and in 1840-41 (6 vols). See Döring's *G.'s Leben* (Leips. 1833).

Gell'ius, Au'lus, a Latin grammarian of good family, flourished 117-180 A.D. The dates of his birth and death are unknown. He studied rhetoric at Rome and philosophy at Athens. On his return to Rome he devoted himself to the legal profession, in which he seems to have been busily occupied during the remainder of his life. His work *Noctes Atticæ*, so called because it was begun and in great part written during the long winter nights in a country-house near Athens, contains dissertations and discussions on an endless variety of subjects, including history, philology, antiquities, and philosophy, and abounds in quotations, many of them from Greek and Latin authors whose works have perished. It originally consisted of 20 books, all of which have come down to us except the 8th, the index of which only has been preserved. The style of G. is marred by the constant occurrence of obsolete words and phrases; but his work is thoroughly readable, and eminently valuable for the light it throws on many points that would have otherwise remained obscure. The *editio princeps* was printed at Rome (fol. 1469). The best critical edition is that of J. Fr. and Jak. Gronovius (Leyd. 1706); the latest is that of Hertz (2 vols. Leips. 1853).

Ge'lon, son of Deinomenes, sprung from one of the most ancient and illustrious families of Gela in Sicily. On the death of Hippocrates in 491 B.C. he became 'tyrant' of Gela, and in 485 B.C. of Syracuse, which he made his capital, and to which he transferred the majority of the inhabitants of Gela and Camarina. By this means he soon raised Syracuse to unexampled power. When the Greeks sought his aid against Xerxes, G. offered to assist them with 200 triremes and a land force of 28,000 men if they would make him commander-in-chief, but to this condition they would not accede. Soon after he assisted Theron of Agrigentum against Terillus of Himera, who was aided by the Carthaginians, and on the day of the battle of Salamis (according to Herodotus), or of Thermopylæ (according to Diodorus), gained the decisive battle of Himera, in which Hamilcar was slain (480 B.C.). Thereupon G. concluded a treaty with the Carthaginians by which they paid the expenses of the war. This sum he devoted to the erection of temples and to offerings at Delphi and other shrines. He died 478 B.C. The Syracusans built a splendid tomb to his memory and decreed him heroic honours.

Gema'ra. See TALMUD.

Gemblou'x (Flem. *Gemblours*, pron. *Changblu*), a quaint old town of Belgium, province of Namur, 25 miles S.E. of Brussels by railway. It has a famous Benedictine abbey, the origin of which is assigned to the 9th c., and from which proceeded the very useful *Chronik des Siegebert von G.* Since 1860 the abbey buildings have been used as a Royal Agricultural Institute. Don John of Austria gained a victory here over the Netherlanders, 31st January 1578. Pop. 3018.

Gem'ini (Lat. 'The Twins'), a constellation of the northern hemisphere, easily recognised in the winter months by its two con-

spicuous stars Castor and Pollux, the latter of which is of the first magnitude, and in the line joining Procyon and the Pole Star. G. is also the name of the third sign of the zodiac.

Gemis'tus Ple'tho, Geor'gius, one of those learned Greeks who so powerfully contributed to the revival of letters in Italy during the 15th c. Born in Constantinople, after the middle of the 14th c. he came to attend the council at Ferrara in 1438, and was persuaded to reside at the court of Cosmo de Medici. He wrote scholia to Thucydides and a history of Greece; but his fame rests on the success of his efforts to revive the Platonic and Neo-Platonic philosophy, and on his zeal as an opponent of the Aristotelians. In this cause he wrote on the differences between Plato and Aristotle (Venice, 1532). His enthusiasm for the pagan philosophy chilled, if it did not entirely destroy, his belief in Christianity. His treatise on Fate was edited at Leyden in 1722; that on the Four Cardinal Virtues appeared at Basel in 1552. G. died about 1441 in the Peloponnesus.

Gemma'tion. See BUDD'ING.

Gemot' (Old Eng. 'a meeting,' from *metan*, 'to meet'), the old English name for a council, as the *Scir-G.*, or assembly of the shire, the *Burh-G.*, *Hundred-G.*, and the *Micel-G.*, or assembly of the whole nation, also known as the Witenagemot (q. v.).

Gems, Ancient. The term gem, though often used to indicate precious stones used for ornamental purposes, properly belongs only to such hard and precious stones (the *pierres fines* of the French) as have engraved upon them devices, figures, portraits, pictorial groups, &c. Minute engravings were in ancient times executed on nearly all the hard precious stones now known, except the diamond, which on account of its hardness presents insuperable difficulties to the engraver's tools. But the stones most suitable for gem engraving were the various forms of coloured and banded quartz and colourless rock crystal. The banded quartzes—the onyx, sardonyx, nicolo, and agate, which only differ from each other in the colours and arrangement of their various strata—were the favourite media for engraving in relief (cameo engraving), the different layers giving great boldness and clearness of outline to their work. For intaglio, or sunk engraving, on the other hand, carnelian quartz, and its fine variety known as sard, chalcedony, and jasper, were very frequently employed. Of much less frequent use were such precious stones as beryls, emeralds, sapphires, rubies, garnets, jacinths, &c.; but many examples of antique engraving on these, as well as on lapis-lazuli, tourmaline, aventurine, obsidian, &c., are still found in collections of A. G. Next to the quartzes, the material most frequently employed was 'paste' or glass imitations of precious stones, in the preparation of which the Romans were highly skilled. Such pastes were evidently in great demand in early times, as imitation jewellery is in the present day.

The implements which the early gem-engravers used were probably only two—the drill and the 'diamond' point. The drill was used for producing the deeper portions of any engraving by making a succession of small holes or depressions in the material. Its cutting effect was produced by feeding its point with fine emery powder mixed with oil. The diamond point, which effected its working by a succession of scratches, was composed of minute splinters of corundum (the *adamantis crustæ* of remote times). These splinters, Pliny remarks, 'gem-engravers greatly value, and mount them in an iron tool, there being nothing so hard that they will not hollow out with facility.' The 'wheel,' an instrument much used by Renaissance and modern artists, was not known to the engravers of the classical period. It consists of a minute disc of copper fixed on the point of a spindle, which is caused to revolve with great rapidity. The edge of the disc, charged with emery or diamond dust mixed with oil, is applied to the surface to be cut away, and it bites its way into the hardest materials with great rapidity. It is evident that under any circumstances the work of gem engraving is of a nature requiring the greatest patience, as well as skilful and delicate manipulation, and considering that ancient engravers worked entirely without magnifiers, the artistic feeling and individuality of their works are marvellous.

The art of gem engraving was developed from the very ancient practice of engraving signets for securing property by their impressions, and for various official purposes. Numerous remains of such signets in Assyrian and Egyptian workmanship still exist, containing rude representations of human and other figures, having no traces of hieroglyphic or alphabetic characters, and therefore presumably more ancient than the invention of arbitrary modes of representing ideas. These primitive engravings are succeeded by another series upon which inscribed characters appear. In the case of the Assyrian they were chiefly executed upon serpentine, and took the form of cylinders engraved around their whole surface. The Egyptian work was cut in the form of *scarabei* or beetles, the material used being soapstone or glazed terra-cotta. Real gem engraving can be traced to Assyrian work dating about the 7th c. B.C., although it is maintained that at least one engraved jasper of Egyptian origin belonging to the 15th c. B.C. exists. It is, however, most probable, as maintained by King (*Handbook of Engraved Gems*), that the Egyptians were long preceded by the Assyrians in the cultivation of the art, and that the former people continued to use soft materials and gold for their signets down to the times of the Ptolemies. From the Assyrians the art passed in succession to the Phœnicians and the Greeks, by the latter of whom gems were for the first time secured in gold settings and worn as finger rings. Gem engraving was a well-recognised art in Greece 600 years B.C., and about that date the famous ring of Polycrates was made by a Samian artist. About the same period the art was cultivated by the Etruscans, who, however, obviously derived their inspiration from Asia and Egypt, and using the scarabeus form, engraved first representations of the lower animals, only rising to the drawing of human figures under the influence of the Greeks. An archaic intaglio of Etruscan workmanship, 'The Five Heroes before Thebes,' is pronounced by Winckelmann to be 'not only the most ancient monument of the art of the Etruscans, but also of art in general.' From the Etruscans the art passed to the Romans, under whom it reached its zenith of perfection and variety.

Down to about 150 B.C. gem engraving was confined to works in intaglio, but then an altogether new branch, cameo engraving, was introduced, which gave an enormous impetus to the development of the art. The primary purpose for which intaglio engravings were executed had always been for use as signets, whereas cameos were introduced purely from artistic motives; and although many magnificent works of art were achieved in intaglio, they cannot compare in artistic and historical value with some of the cameos which are preserved to our own times. Although any engraving on a hard or precious stone executed in relief may be regarded as a cameo gem, yet true cameo engraving requires for its perfection such stones as enable the artist to throw his work into distinct relief by two or more coloured strata. Gem portraits, which began to appear in the era of Alexander the Great, soon came to be executed in great abundance in cameos, and the authentic portraits we possess of many of the most prominent persons in ancient history are derived from these. The most valuable cameo still extant is the 'Tiberius,' or great cameo of the Sainte Chapelle, preserved in the Bibliothèque Nationale, Paris. It is a work containing twenty-four figures and accessories representing the triumph of Germanicus, executed on a sardonyx of five layers. This magnificent gem was sold to St. Louis of France by Baldwin II. (q. v.), the last of the Latin Emperors of the East, along with various relics of our Saviour, for £20,000. Though less in size, the Vienna cameo, 'The Coronation of Augustus,' is even of greater artistic excellence. The Carpegna cameo in the Vatican collection is by far the largest gem in existence, measuring 16 inches long by 12 deep, its subject being Bacchus and Ceres.

Gem engraving in all its departments, including the fabrication of pastes, reached its highest perfection during the period of Augustus, and for two or three centuries thereafter the art was maintained in its fullest vigour and development. But after the reign of Severus it rapidly declined, and in the 5th c. Roman gem-cutting may be said to have become extinct, dying away in fantastic and ill-executed works which were employed and valued as amulets and charms. It was not till the Renaissance period, about the beginning of the 16th c., that it was again revived on the very soil where it had flourished so vigorously more than a thousand years before; and attained even greater perfection than in classic times. In the last century many instances occurred of the fabrication of spurious antiques and the falsification of genuine ancient gems by inserting inscrip-

tions purporting to be the names of their original engraver. The Poniatowsky collection was the most remarkable example of such, containing as it did about 3000 works all signed ostensibly by the greatest artists of ancient times. The prevalence of these forgeries did infinite harm to the art, introducing doubt and confusion into the minds even of the most experienced amateurs; and to the disgraceful practice was doubtless due in large measure the extinction of the art. Gem engraving is now only practised as a handicraft for producing seals or small works altogether devoid of artistic significance. Cameo cutting is confined to works in shell and other soft material, which do not bring it within the province of gem engraving. See CAMEO.

In addition to the artistic value which A. G. possess, they preserve to modern times the most faithful representations of the dress, habits, and usages of the remote perious whence they have come down. On many historical events they throw much light, and they help to interpret innumerable obscure allusions and remarks in classical writers. No less valuable are they for preserving a faithful representation of the features of the great rulers, statesmen, poets, and philosophers of antiquity, and thus knitting in closer ties the thought and life of widely-removed epochs. See Marriette's *Pierres Gravées* (1750); Raspe's *Catalogue der Impreintes der Pierres Gravées; Tassie Gems* (1791); King's *Antique Gems* (2d ed. 1866); *Handbook of Engraved Gems* (1866); *Antique Gems and Rings* (1872).

Gems, Artificial. The artificial production of precious stones is a subject that has of recent years engaged the attention of some chemists, among others Ebelmen, Sainte-Claire Deville, Caron, Becquerel, and Wöhler. In 1858 Deville and Caron communicated to the *Académie des Sciences* of Paris the fact that they had produced small gems of the corundum class—as the ruby and sapphire—by exposing to a white heat the fluoride of aluminum mixed with a little charcoal and boracic acid in a crucible. Their process is detailed in *Comptes Rendus, Annales de Chimie*. In 1870 M. Gaudin, and in 1873 M. Ch. Feil, gave to the same learned Society the results of their researches in this field. In fusing the materials they employed the flame of the oxyhydrogen blow-pipe. Gaudin's A. G. were deficient in hardness, but possessed the other qualities and composition of the natural stones. Feil has produced a rose-coloured stone, composed of almost pure alumina fused with the aid of borax, that emits the phosphorescent light of the ruby.

Gems, Imitation, or **Pastes,** are composed of a dense transparent glass of great purity and lustre. The Romans produced, among other mock gems, admirable imitations of the emerald and lapis-lazuli. Early in last century Strass, a German chemist, fabricated a vitreous base, which now bears his name, and employed it for I. G. Its percentage composition is thus given by Dumas:—Silica, 38·5, potash, 7·5, alumina, 1·0, oxide of lead, 53. The diamond is imitated with white strass; for coloured gems a little of the metallic oxides used by enamellers is added to the base. Large quantities of cheap I. G. are made at Septmoncal in the Jura. The Parisians take the lead in this art. They employ, besides strass, a paste called *diamant de bore*, of which borax is believed to be the main ingredient. The paste possesses great hardness, with the brilliancy and refractive power of the diamond; and when skilfully cut, polished, and set, it is difficult to distinguish it from true brilliants. In the manufacture of I. G. great care is taken. The ingredients are selected of great purity, and well pulverised and sifted; the fitness of the crucibles to resist intense heat and chemical action is tested; and the fusion and cooling of the paste are slowly conducted.

Gems-Boc, or **Gems-Bok** (*Oryx gazella*), a species of Antelope (q. v.), also known as the *kookaamis*, a typical inhabitant of S. Africa, and distinguished by its grey colour, which is varied by a deep black spinal marking, the latter hue also being found on the hinder quarters, flanks, and face. A short mane is developed. The tail is long and black, and the horns are straight and slope backwards, while they are annulated at their bases only. No *crumen* or 'tear-bag' exists. The G. inhabits arid plains and barren wastes, and appears to feed largely upon succulent plants, the juices of which serve in lieu of water. It will resist the attack of the lion, and defend itself with great courage and skill by means of its sharp horns. The flesh is very highly esteemed.

Gen'darmes, or **Gens d'Armes** (Fr. 'men-at-arms'), the name given first to the heavy French cavalry during the 14th and 15th centuries, then to a cavalry corps which formed a royal body-guard to the Bourbons, and now applied to the French military police, which contains both cavalry and infantry.

Gen'der (Fr. *genre*, formed from the ablative of the Lat. *genus*), in grammar, is the distinction of nouns according to sex. In English all names applied to males are said to be of the *masculine* G., those applied to females of the *feminine* G.; all others are said to be of the *neuter*, *i.e.*, of *neither* G. Properly speaking, as there are only two sexes, there are only two genders; but the term neuter G. is sanctioned by universal usage, and under this head all names of inanimate objects ought to fall. Owing, however, to the process of personification, such objects are often spoken of as animate, conscious, or sentient beings, and as such are invested with sex according to the analogy suggested. Thus the sun, considered as a god, is masculine; the moon, as a goddess, is feminine. So also in figurative language *time* is masculine, while such nouns as *earth, ship, country, town, virtue*, &c., are feminine. In Latin Greek, Sanskrit, &c., many nouns of inanimate objects have from this cause become masculine, others feminine; their G. must accordingly be ascertained from their terminations, which are in all probability the remnant of suffixes indicative of the sex originally assigned to the object spoken of. For example, the terminations *us, a, um* in Latin, *os, ē* or *a, on* in Greek, in many instances represent the masculine, feminine, and neuter genders respectively, both in nouns and adjectives. In English the G. of the noun affects the form of the third personal pronoun (*he, she, it*) alone; whereas in all the highly-inflected languages adjectives (including articles and participles) have different forms for the different genders. Hebrew, Italian, French, Spanish, and Portuguese have no neuter G.; German, like the classic languages, distributes inanimate objects over the three genders. In the matter of G., English, strictly following the order of nature, is the most rational of all tongues. Indeed, nothing can be more absurd than that the name of any one thing should be both masculine and feminine, or masculine and neuter, in the same language, or masculine in one language and feminine or neuter in another. In English there are three methods of distinguishing the G.—(1) by different words, as *bachelor, maid*; (2) by a difference of termination, as *actor, actress*; (3) by prefixing a noun, pronoun, or adjective to the substantive, as *man-servant, maid-servant; he-goat, she-goat; male-child, female-child.*

Geneal'ogy (Gr. *genealogia*, from *genos*, 'race,' and *logos*, 'a discourse') is the science of family origin and descent. It embraces the history of the succession of families from remote ancestors, of the various families which have a common origin, and of the different lines which centre in each individual. In the earliest historical ages we find that genealogy was carefully attended to. No nation has excelled the Jews in this respect. Some of the princely families of India and of other Eastern nations can show pedigrees that almost make *parvenus* of the oldest European families. G. was of supreme importance in feudal times, and it is still of great value in a legal point of view from the inheritance of land and the succession to hereditary titles. It also possesses a deep interest from a scientific and historical point of view. It has an intimate connection with physiology and psychology, and by exhibiting the growth, transmission, and combination of hereditary qualities it may yet throw much light upon many mysteries in character and conduct. G. has become within the present generation a very important study in the United States, having an extensive literature of its own. See for England, Collins's *Peerage of England* (new ed. 9 vols. 1812); Henry Drummond's *Histories of British Families* (2 vols. Lond. 1846): for Scotland, Douglas' *Peerage of Scotland* (2 vols. Edinb. 1813), and his *Baronage* (Edinb. 1796); Crawford's *Peerage* and other works; Anderson's *Scottish Nation* (3 vols. Edinb. 1863); *Retours*, or *Inquisitionum ad Capellam Domini Regis Retornatarum, Scotiæ*, &c. (3 vols. 1811–16): for the United States, Savage's *Genealogical Dictionary of the First Settlers of New England* (4 vols. Bost. 1860–62); *The New England Hist. and Genealogical Register* (periodical). For Europe generally

Hübner's *Genealogische Tabellen* (4 vols. Leips. 1725–33, new ed. 1737–66); Gatterer's *Abriss der Genealogie* (Gött. 1788); Koch's *Tables Généalogiques des Maisons Souveraines d'Europe* (Ger. Berl. 1808); Voigtel's *Geneal. Tabellen* (1810); also Vehse's *Geschichte*. On royal families, Lavoisne's *Atlas* (Phil. 1820; new ed. Lond. 1841) is very useful. For the literature of the subject consult Moule's *Bibliotheca Heraldica* (Lond. 1822).

Gen'eral, used of monastic institutions, is the term for the supreme head of a religious order, who is responsible to the Pope alone. He is elected, usually for three years, by the general chapter of the order, over which he then presides. The general chapter consists of the provincials, each of whom is head of all the communities belonging to an order throughout a province. The *admonitor* appointed by the order as adviser to its G. has no control over his decision.

General Assembly. See ASSEMBLY, GENERAL.

Generalisa'tion, as defined by Whately, is the act of comprehending under a common name several objects agreeing in some point which we abstract from each of them, and which that common term serves to indicate. This may, at least, be taken as a definition of the G. of *notions*. Thus from the consideration of the earth as a body moving round the sun, we arrive at a conception of the generalised notion implied by the word planet. The grouping of individuals in families, species, genera, orders, &c., is a succession of generalisations, each of which is wider than its predecessor. It is therefore apparent that G. leads up to classification, depending itself upon the process of abstraction. To generalise we must first abstract; though it is conceivable, as pointed out by Herbert Spencer, that abstraction may be possible without G.

A higher species of G. is what may be termed the G. of *propositions* or inductive G. (See INDUCTION.) For instance, consider the proposition that the earth moves round the sun in an ellipse. Inasmuch as the earth moves round the sun, it is, as we saw above, a planet; and when we extend this other attribute of the earth's motion, ellipticity, to such bodies, we form a generalised proposition which may or may not be true, viz., Planets move round the sun in ellipses. To generalise thus is necessarily hazardous, but the process has always played a most important part in the progress of science. When Werner, towards the close of last century, from careful observation of the succession of strata in his own neighbourhood, concluded that all formations in all parts of the world were laid down in the same order, and must have been deposited by the same agency—a universal ocean—his generalisations were hasty and false. On the other hand, the enunciation by Newton of the universal law of gravitation, which was the result of the demonstration by calculation that the moon was held in its path by the same force which made a stone fall to the ground, is a most perfect example of a true G. Of all generalisations the grandest is the modern theory of the Conservation of Energy—a true induction from our only source of accurate knowledge, experience.

General Officer. In the middle ages a commander who had captains under him was styled a captain-general, and the adjective *general* has from this use become a substantive signifying an officer with independent command. G. O. is applied to any officer higher than a colonel. At the head of all is the commander-in-chief or field-marshal, beneath whom come generals, lieutenant-generals, major-generals, and brigadier-generals. In England the office captain-general is merely nominal, and is held by the sovereign.

General Quarter Sessions, Court of. This court is held in England by two or more justices of the peace in every county and division of a county once every quarter of a year, for the trial of misdemeanours and other breaches of the peace. Under 1 Will. IV. c. 70, these sessions must be held in the first week after 31st March, 24th June, 11th October, and 28th December. Justices may, however, direct the April quarter sessions to be held any time between 7th March and 22d April, so as not to interfere with the spring assizes. For Scotland, see QUARTER SESSIONS, JUSTICES OF THE PEACE.

General Ship. A trading ship is so called which has been advertised to carry goods from a particular port at a stated time, and which is under no special contract. If the destination be stated, and an alteration subsequently made, the owners' must give notice of the change; and should they omit to do so, they are liable for the consequences. Contracts should be made with the master, not with the owner, of the vessel. Usually there is no other evidence of contract except the advertisement and the bill of lading. These may be supplemented by parole evidence.

General Verdicts. In criminal cases the usual verdict is 'guilty' or 'not guilty,' or in Scotland 'not proven;' in civil cases it is a verdict for the plaintiff or for the defender. These are called G. V. in contradistinction to Special Verdicts (q. v.).

Genera'tion, the function of living bodies whereby the losses which death is continually making upon the species of animals and plants are repaired and made good. Reproduction of the *species* stands in a manner antagonistic to the *nutrition* of the individual, since the reproductive energies act antagonistically to the nutrition of the form, by demanding the exercise of powers which weaken and destroy it. G. in the animal world is accomplished in various ways. The various modes of reproduction may thus be tabulated :—

REPRODUCTION may be effected	(A.) ASEXUALLY, without the operation of the elements of *sex*, as by	(*a.*) *Fission*, or simple division of the body. (*b.*) *Gemmation* or budding, which may be (1) *continuous* or (2) *discontinuous*.
	(B.) SEXUALLY, by the operation of the *male* and *female* elements, and may be performed by individuals which are	(*a.*) *Diœcious*, *i.e.*, having the sexes in distinct and separate individuals. (*b.*) *Monœcious* or *Hermaphrodite*, *i.e.*, having both sexes in one and the same individual.

In the plant creation, similarly, G. may be performed by monœcious or diœcious individuals. Some plants are sexually *perfect*, *i.e.*, have *stamens and pistil* (corresponding to male and female organs respectively) in the *same flower*; or *monœcious*, *i.e.*, have stamens in one flower and pistils in other flowers of the *same plant*; or *diœcious*, *i.e.*, have staminate flowers in one plant, and pistillate flowers in another and *distinct plant*. Asexual modes of G. in animals are exemplified in many *Invertebrata*. Thus the *Vorticellæ* or 'bell animalcules' among the *Infusoria*, and other members of the latter class, illustrate the process of fission, the bell-shaped heads of these animalcules dividing into two separate beings. The *Amœbæ* and other *Rhizopoda*, among the lower *Protozoa* do the same. The process of *gemmation* or *budding* is well seen in the fresh-water polypes, or *Hydræ* (q. v.), in which a young form buds out from the side of the parent, but sooner or later detaches itself. This is termed *discontinuous* gemmation. In the zoophytes and corals the buds may grow into forms resembling the parent organism, and may remain permanently attached thereto, thus constituting a *compound* animal. In the latter case, the budding is said to be *continuous*. A *compound* animal consists of separate organisms, each of which is termed a *zoöid*; and as the *individual* animal in zoology is regarded *as the total result of the development of a single ovum or egg*, the entire organism of a compound form forms the individual, since it may be proved to have originally sprung by continuous budding from a single egg. In *sexual reproduction*, as already defined, the elements of the *male* and *female* sexes take part. These elements consist in the production by the female of an *ovum* or egg, and by the male of the *seminal fluid* or *semen*, the characteristic parts of which fluid consist of certain minute animalcular and living bodies named *spermatozoöids*, or *spermatozoa*. The performance of the sexual mode of reproduction consists essentially in the *fertilisation* or *impregnation* of the egg of the female by contact with the spermatozoöids of the male. Thereby a certain series of changes is induced, which results in the formation of a new being. What the exact nature of the contact is, which takes place between the male and female elements, physiology cannot as yet tell. But it appears highly probable that this contact is not only effected by the spermatozooids actually penetrating the covering of the egg, but that the influence of the male may in some cases extend or be transmitted thus to many subsequent generations of progeny. Occasionally certain cases may occur in the animal series, as among the plant-lice or *Aphides* (see APHIS) (*Hemiptera*), in which virgin or unimpregnated females appear to be capable of producing progeny without contact with a male. This peculiarity has received the name of *Parthenogenesis* (q. v.). The explanation of this anomaly appears to be that the bodies which give rise to the young of such

females are not true *ova* or eggs, which would require fertilisation before developing new beings, but are simply *pseudova* or false eggs, resembling *internal* buds or *gemmæ*, and produced by an *asexual* process of G.

The presence of sexuality in plants has already been referred to —the *stamens* constituting the male organs and the *pistil* the female organs of vegetables. In early times the Egyptians knew that dates were produced by bringing the two kinds of flowers into contact. Theophrastus mentions the *sexes* of plants, and Pliny speaks of *male* and *female* palms. Grey in 1676 first definitely determined the sexuality of plants, in a paper read before the Royal Society; and this botanist appears to have had pretty clear notions that the *pollen* from the stamens was the matter which fertilised the seeds contained in the *pistil*. Ray and Camerarius—the latter of Tübingen—advocated the views of Grey, and in due time Linnæus (1736) definitely expressed his belief in the sexuality of plants. Linnæus, however, was not aware that in the lower (cryptogamic or flowerless) plants truly-defined sexual organs also existed. This subject was finally investigated by Treviranus (1815), Amici, and Robert Brown, whilst the researches of Hofmeister, Suminski, and others on cryptogams have enabled us to clearly comprehend the reproductive processes of the lower groups of plants.

Generation, Eternal. See TRINITY.

Generation, Sponta'neous, the name given to indicate a belief in the origin of living beings, and especially of the lower forms of animal and plant life, from inorganic matter. When living beings are said to come *spontaneously* into existence, they are believed to originate without the *pre-existence* of a parent organism or organisms. The ancients, with imperfect knowledge of the development and general physiology of living beings, were firm believers in S. G., or *abiogenesis* as it is more commonly termed in modern biology. That putrefaction and the decay of animal and vegetable matters should give origin to living beings appeared to be a fact which the daily experience of life seemed in every way to corroborate, and it was only about the middle of the 17th c. that Francesco Redi, a physician of Florence, first refuted the common belief by showing that the maggots which appeared in decaying meat sprang from eggs deposited in the meat by the parent flies. Redi's experiment consisted in placing gauze over the meat to exclude the flesh-flies, when the process of decomposition went on as before, without the production of maggots or larval flies. Redi adopted as his motto the expression *Omne vivum ex vivo*.

After Redi's day and generation the microscope began to be perfected; and although the idea of animals of such high organisation as insects being spontaneously generated was given up, the discovery of many forms of animalcular life renewed the theory of S. G., as explanatory of the origin of the lowest animals and plants. Needham and Buffon in the middle of the 18th c. experimented upon the production of animalcules in infusions, and came to the conclusion that these animalcules were produced by S. G.; inasmuch as, notwithstanding their precautions of boiling and carefully sealing their infusions, they continually found animalcules developed in them. They therefore supported the doctrine of abiogenesis, against that of *biogenesis*; according to which all living things originate from pre-existing forms of life. The Abbé Spallanzani repeated Needham's experiments, and by the exercise of greater care showed that it was possible to keep sealed infusions without developing any animalcules; and in 1836–37 Schulze and Schwann, filtering the air admitted to infusions through sulphuric acid and through red-hot tubes, found that no animalcular life was developed. In 1854–59 Schröder and Dutsch used cotton-wool to filter the air and so to protect their infusions, with the same result. Quite recently the experiments of Tyndall have proved that the air contains multitudes of germs, and that the atmosphere therefore acts as the medium for the conveyance of these germs to situations (as among decaying matters) in which they may spring up into their mature and adult forms. The 'germ theory' of disease, which accounts for the spread of infectious diseases on the assumption that these germs are conveyed by the atmosphere, rests on the facts just stated, and receives much support from the experiments and surgical practice of Professor Lister of Edinburgh, who prevents suppuration and putrefaction in wounds by protecting raw surfaces with gauze and dressings rendered antiseptic or germ-destroying by being steeped in carbolic acid. The doctrine of *biogenesis* is thus accepted in the present day by almost all naturalists. Some few authorities (amongst whom Dr. H. C. Bastian of London stands pre-eminent), however, still declare their adherence to the doctrine of S. G., and believe that the lower forms of life may be developed from inorganic matters and without the pre-existence of parent organisms. The reader will find in Dr. Bastian's work entitled *The Beginnings of Life* a full *résumé* of the subject, and of experiments conducted in support of his views.

In the present day the following statements may be held to briefly summarise this great controversy:—(1) Whether or not S. G. be ever proved to be a possibility or to actually occur, there can be no doubt whatever that many lower organisms are propagated in decaying matters through their *germs*, borne by the atmosphere, finding an appropriate resting-place in such matter, and there springing up into adult forms of life. (2) It has been abundantly proved that the atmosphere contains a large quantity of *germinal* or *organic* matter amongst the floating *débris* and dust it carries mechanically suspended in it. (3) Experiments which seem to favour the idea that S. G. may occur are liable to fallacy and error, since it has not been proved that germs are destroyed by even intense heat. The belief that cases of living beings appearing in infusions carefully protected from the atmosphere, are explicable on the ground that the germs may have previously been contained in the fluids of the infusion, and have not been destroyed by heat, is thoroughly warranted and feasible. (4) The advocate of S. G. has the disadvantage of having to maintain that the ordinary laws of nature and of reproduction must be continually set aside. And lastly, when cases of Dormant Vitality (q. v.) occur among such highly organised creatures as the *Rotifera* (q. v.), or 'wheel animalcules,' it may be reasonably assumed that living matter may simulate states of seeming death, and yet be capable of easy and quick revival.

Generations, Alternation of. See ALTERNATION OF GENERATIONS.

Genera'tor, in mathematics, is a point, line, or surface by whose motion a curve or surface may be described or *generated*. Thus a point moving round a fixed point at a constant distance from it describes a circle, and a straight line rotating round a fixed line not in the same plane generates an hyperboloid.

Genesee', an American river which rises in Pennsylvania, flows through New York, and, after a course of 120 miles, through a fertile and romantic district, enters Lake Ontario, 7 miles N. of Rochester. It is navigable for 5 miles, and has remarkable falls at Portageville and in the neighbourhood of Rochester.

Gen'esis, the first book of the Hebrew Scriptures, received its name (in full Gr. *genesis kosmou*, 'creation or origin of the universe') from the subject of its contents. The plan of the book, as it now stands, is easy to be seen. It is, in a word, to trace the history of Israel as the chosen people of God from the creation of the world. The history, which embraces a period of 2390 years (from Adam to the Flood, 1656, v., vii. 11; till Abram left Haran, 368, xi., xii. 4; to the death of Joseph, 286, xxi. 5, xxv. 26, xlvii. 9, add 71 of Joseph's life, l. 26, *cf.* xli. 46, and add 7 years of plenty and 2 of famine), is divided naturally into two eras by the Flood. The history of the creation of the world, and of the fall of man from a state of primeval innocence (i.–iii.), is followed by the history of Adam's descendants to the death of Noah (iv.–ix.). From the nature of the case the history so far is entirely general, and is therefore a mere introduction to what follows. But from the Flood the history traces step by step how the children of Israel were chosen out of all the families of the earth to be the people of God. After the descendants of Noah are enumerated, by whom the earth was peopled (x.–xi. 9), two of the three sons are dropped, and only the generations of Shem traced, down to Abraham (xi. 10–32). Of Abraham's children, Ishmael and those by Keturah are summarily dismissed (xxi. 9–21, xxv. 1–6, 12–18), because the history is chiefly concerned with the history of Isaac (xii.–xxiv.). In his sons the final election takes place; Jacob obtains the birthright, his father's blessing, and also the title of 'Israel' (xxv.–xxxv.), while the descendants of Esau are dismissed with a genealogy (xxxvi.). After that the history of Jacob's sons is

carried on to the death of Joseph (xxxvii-l.). Otherwise, the contents are divided into ten sections besides the first chapter, beginning each with the heading *These are the generations*:—1. Of the heavens and earth (ii. 4-iv. 26); 2. of Adam (*This is the book of the generations*, v. 1-vi. 8); 3. of Noah (vi. 9-ix. 29); 4. of the sons of Noah (x. 1-xi. 9); 5. of Shem (xi. 10-26); 6. of Terah (xi. 27-xxv. 11); 7. of Ishmael (xxv. 12-18); 8. of Isaac (xxv. 19-xxxv. 29); 9 of Esau (xxxvi.); 10. of Jacob (xxxvii. 2-l.). Such is the design and plan of the book as it now stands.

Authorship.—The general or common belief is that G. was written by Moses when he wrote the rest of the Pentateuch, its facts having been communicated to him by supernatural revelation. But from various indications in the book itself the opinion was broached as early as the 17th c. (*e.g.*, by Simon and Le Clerc) that he derived his information from previously-existing documents. The view that G. is founded on older documents has been adopted still more strongly by those critics who place the composition of the Pentateuch at a later time than that of Moses altogether. The warrant for the assumption is found (1) in certain supposed indications of a later date, (2) in the introductory clauses by which certain portions are separated from what goes before, (3) in the repetitions of the same or very similar events, and (4) in the difference in style and language which is evident when various parts are compared, and particularly in *the naming of the deity*. For example—(1) The mention of *Dan* (xiv. 14), a name which the town did not receive till long after Moses (Josh. xix. 47; *cf.* xiv. 2, 3, 7, 17, xxiii. 2, xxxv. 19, 27); ch. xxxvi. 31, which seems to imply that one or more kings had reigned over the children of Israel; ch. xii. 6 and ch. xiii. 7, which seem to imply that when they were written the Canaanite was no longer in the land; ch. l. 11, which would seem to imply a writer who lived in the land of Canaan, &c. (2) The headings of the ten sections mentioned above. (3) The adventure which happened to Abraham and Sarah, and to Isaac and Rebecca, in both cases with Abimelech, King of Gerar (xx. xxvi.); the twofold account of the creation (i.-ii. 3, and ii. 3 to end), of the entering into the ark (vi. 9-22, vii. 9-16, and vii. 1-8), of Esau's wives (xxvi. 34 and xxviii. 9, and xxxvi. 2, 3), and of the origin of the names Bethel (xxviii. 19 and xxxv. 9-15), Israel (xxxii. 28 and xxxv. 10), and Beersheba (xxi. 22-32 and xxvi. 17-33). (4) Varieties of style and language, the most conspicuous of which is the use of the two chief names of the Deity—Elohim (A. V. God) and Jehovah (Lord). Sometimes the one name is used throughout a passage, sometimes the other—a peculiarity which is rendered the more striking by the fact that the difference is observed just in those passages which there appear to be *other grounds* for believing to be composed by different writers, *e.g.*, in the two accounts of the creation, the entering into the ark, and the origin of Beersheba above.

The first who laid particular stress on the names of the Deity, of which so much has been made by modern critics, was Astruc, a French physician, in his *Conjectures sur les Mémoires Originaux, dont il parait que Moyse s'est servi pour composer le Livre de Genèse* (Bruss. 1753). He assumed the existence of two chief sources which pervaded the whole of G., an Elohim document and a Jehovah document, and other ten minor ones. Eichhorn held (*Einleitung ins A. T.*, 1823) that G. was founded on two pre-Mosaic documents, Elohistic and Jehovistic. De Wette (*Einleitung*, 1806) supposed that the chief source of G. is a continuous Elohistic writing, extending down to Exodus vi., with which the author of the existing book interwove matter out of one or more Jehovistic documents. He was followed in essential points by Von Bohlen, Bleck, Tuch, Knobel, Delitzsch, and Bishop Colenso. The theory of the last is that the Book of G. grew to its present shape by degrees, different writers (whom he distinguishes as the second Elohist, first, second, and third Jehovist, and the Deuteronomist) introducing from time to time into the original narrative such matter, generally supplementary, as they considered important. He professes to be able to pick out from the whole book the Elohistic narrative, in a series of passages which may be read continuously—i.-ii. 3, v., vi. 9-22, vii. 6-24, viii. 1-19, ix. 1-17, 28, 29, xi. 10-32, xii. 4*b*, 5, xiii. 6, 12, xvi. 1, 3, 15, 16, xvii., xix. 29, xxi. 2-5, xxiii., xxv. 7-26, xxvi. 34, 35, xxviii. 1-9, hiatus, xxix. 24, 29, 32-35, xxx. 1-24, xxxi. 18, xxxv. 9-29, xxxvi. 1-19, 31-43, xxxvii. 1, 2, 28*a*, 36, xlvi. 6-27, xlvii. 7-11, 27, 28, xlviii. 3-7, xlix. 1*a*, 29-33, l. 13.

On the other hand, many eminent scholars have all along opposed these opinions. Ewald, *e.g.*, in his first work (*Die Composition d. G.*, 1823), sought to weaken the argument from the different names used for God by showing that the use of them in G. is always fixed by rules grounded on the usages of the Hebrew language. In the opinion that no written documents were made use of by Moses in the composition of G., an opinion which he afterwards abandoned, he has been followed by Sack, Hengstenberg, Havernick, Ranke, Drechsler, M. Baumgarten, Wette, J. H. Kurtz, Keil, and Smith's *Chaldæan Account of Genesis* (1875). Since the publication of this last work, the question as to the authorship of G. has entered on an entirely new phase. See PENTATEUCH.

Genette' (*Genetta*), a genus of Carnivorous *Mammalia*, very nearly allied to the *Viverridæ* or Civets (q. v.). The genettes have a musk pouch, although in a less perfectly developed state than that of the civets. They are nocturnal in their habits. The common or blotched G. (*G. tigrina*) inhabits S. Africa, but also occurs in S. Europe. Its colour is greyish yellow, with bands and patches of black. The claws are semi-retractile. The pale or Senegal G. (*G. Senegalensis*) is a second species, which, like the common G., is susceptible of domestication. The Amer G. (*G. Amer*), a native of Abyssinia, has a fur spotted with dark markings.

Gene'va (F. *Genève*, Ger. *Genf*, Ital. *Ginevra*), the most westerly canton of Switzerland, lies at the S.W. end of the lake of the same name, and is encircled on the E., S., and W. by the French department of Haute Savoie. Area, 109 sq. miles; pop. (1870) 93,239. It has an undulating surface, rising to a height of 1620 feet above the sea-level, and is traversed by the winding Rhone, which receives the Arve 2 miles S. of the lake. Industry has triumphed over an unpromising soil, and of the surface 40 per cent. is under the vine. G. has 3000 horses, 7950 horned cattle, 1900 swine, 920 sheep, and 1165 goats. The chief mechanical industry is the making of watches (100,000 are yearly exported), musical boxes, scientific instruments, and bijouterie. The people, who almost entirely speak French, belong in nearly equal proportion to the Roman Catholic and Reformed Calvinistic Churches. G. is a representative democracy, there being a member of the Grand Conseil for every 666 inhabitants. The members must be over twenty-five years of age, the voters over twenty-one. A council of state of seven members, elected for two years, holds the executive. All forms of worship are allowed. The chief towns are G. and Carouge.—**Lake of G.** (the *Lacus Lemanus* of the Romans), lies mainly between the French department of Haute Savoie in the S. and the Swiss canton of Vaud in the N., is of crescent shape, and touches in the W. and E. the cantons G. and Valais respectively. It is 55 miles in length along the N. bank, 48½ along the S. bank, and has an extreme width of 9 miles, and a depth of 1014 feet near Meillerie. The E. horn has been silted up for 9 miles by the alluvium brought down by the Rhone, which flows through the lake. The wild rocky southern shore contrasts with that of the N., where the gentle slopes are clad with the walnut, the sweet and wild chestnut, the magnolia, the cedar of Lebanon, and the vine. The deep-blue colour of the lake distinguishes it from the other Swiss lakes, the waters of which are of a greenish hue. It occasionally rises several feet without any apparent cause, currents (*ardyres*) are very strong, and waterspouts now and then occur. The lake, which is never entirely frozen over, has but slight navigation. Of fish there are twenty-one different kinds, the chief being the *ferraz*. The L. of G. is inferior in grandeur to the Lake of Lucerne, while in charm of picturesqueness it is far surpassed by Lake Zürich. Mont Blanc is visible only from the W. bank; from the S. Jura may be seen. Among those who have written, however, with enthusiasm on the scenery of the lake are Voltaire, Rousseau, Goethe; it is also the theme of some exquisite stanzas in the third canto of *Childe Harold*.

Geneva, the capital of the canton of G., and the largest and wealthiest town of Switzerland, lies on both sides of the Rhone where, with the swiftness of an arrow, it leaves the Lake of G., and is 70 miles N.E. of Lyon, with which it is connected by railway. It consists of the city proper, the G. of history, on the left bank of the river, the industrial portion of St. Gervais on the opposite bank, and between these the small Quartier de l'Isle, 831 by 139 feet. The river, which

is 600 feet broad, is crossed by six bridges, and of these the handsomest, the Pont du Mont Blanc, nearest to the lake, was completed in 1862. A second little island called Rousseau's, from its having a bronze statue of Jean Jacques (by Pardier, 1834), is planted with trees, and is reached by a small chain suspension bridge from the middle of the Pont des Berques. G. was formerly fortified, but only in the S.E. are there portions of the walls remaining, where they have been converted into promenades. The best and broadest streets are La Corraterie, part of the ancient fosse; the Rues Basses, a series of streets intersecting G. from E. to W.; the Rue de Rhone, running parallel to the river; and the Boulevard Helvétique. Great improvements have been made, especially in St. Gervais, since the construction of the railway. Fine quays extend along both banks of the Rhone, and two jetties projecting on either side into the lake form the new harbour. From the Quai de Mont Blanc, on the left, a magnificent view is obtained of the Mont Blanc group. The Jardin Anglais stretches along the Grand Quai du Lac, and at the city end rises the National Monument, a bronze group of Helvetia and G. on a lofty pedestal, by Dover, in memory of the union of G. with the Confederation in 1814. Among the chief buildings are the cathedral of St. Pierre, completed in 1024 by the Emperor Konrad II., in pure Romanesque, but much altered in the 12th and 13th centuries, and finally disfigured by the addition of a Corinthian portico in the 18th c.; the Hotel de Ville, in the Florentine style, has in the interior planes instead of staircase; the Academy, with lecture-rooms, laboratories, and collections, erected 1867-71 by the city and canton at a cost of £50,000; the Bibliothèque Publique, founded by Bonnivard, the prisoner of Chillon, in 1551, and containing 80,000 vols. and 500 MSS. G. has also a university dating as far back as 1368, but reorganised by Calvin in 1538; an arsenal; a botanic garden laid out by De Candolle in 1816; a fine art athenæum; a museum of pictures, casts, &c., founded by the Russian General Rath; another, with fine Etruscan collections, originated by M. W. Fol; a natural history museum, containing the famous collections of Delesseret, Pictet, De Saussure, Melly, Reviliod, &c.; a Russian church with glittering domes, a synagogue, a conservatoire de musique, and a theatre (1782). The environs of G. are very beautiful, both banks of the lake being studded with fine villas. Chief among the industries is the making of watches, of which 200,000 are produced yearly. The annual value of the bijouterie is about £480,000. Other manufactures are mountain shoes, carved wooden articles, musical boxes, &c. Pop. (1870) 46,783, of whom more than half are Calvinists. French is the prevailing language.

G., which is first mentioned by Cæsar, early belonged to the Allobroges, with whom it passed under Roman rule. On the decay of the empire it fell under the power of the Burgundians, who had settled in Eastern Gaul. In 536 it passed to the Franks, and in 870 to the new kingdom of Burgundy. Konrad II., after subduing Burgundy, was proclaimed king here for the second time in 1034. The bishopric of G., which had existed from the 5th c., became an object of fierce dissension between the Counts of Savoy and those of G., and in the midst of their struggles the citizens joined the Swiss Confederation by concluding an alliance with Freiburg (1518) and Bern (1526). Two parties were thus formed in G., the Confederates (Ger. *Eidgenossen*, by the Fr. pron. *Higuenos*, whence probably the term Huguenots) and the 'Mamelukes,' partisans of the House of Savoy. After the outbreak of the Reformation the bishop transferred his seat to Gex in 1535, and the Reformed religion was legally established, and vigorously preached by Farel (q. v.). In 1541 Calvin (q. v.) settled here to enter on his rigorous career of religious dictator, and henceforth G. became a centre of Protestant education and intense mental life. Opening its gates to evangelical refugees, it received also many philosophers and free-thinkers. The last effort of the Dukes of Savoy to recover G. in 1602 was abortive. In the 18th c. G. was torn by intestine strife, which was eventually settled in behalf of the aristocratic party. The government, however, was overthrown in 1794, and replaced by a national convention. The French annexed G. in 1798, making it capital of the department *Du Léman*, but it was liberated, and admitted into the Swiss confederation in 1814. The attempt to introduce Jesuits led to a violent change of the aristocratic for a republican government in 1848. G. was the seat of a violent peace congress in 1867 and of the Alabama Commission in 1871-72. Monseigneur Mermillod was nominated Bishop of G., but expelled in the latter year. See, besides the older histories of G. by Spon, Picot and Berenger, Pictet de Sergy's *Genève, Origine et Développement de cette République* (Gen. 1845); Thourel's *Histoire de Genève* (3 vols. Gen. 1833); Galiffe's *Quelques Pages d'Histoire* (Gen. 1863); Roget's *Histoire du Peuple du Genève* (3 vols. 1876).

Geneva, the name of twelve towns and villages of the United States, the chief of which is in New York State, at the N.W. end of Seneca Lake, half-way between Rochester and Syracuse, and 50 miles distant from either. It is a great railway terminus, and owes its prosperity to the nurseries, which cover 10,000 acres, and export over one million dollars worth of stock to the various states and to Canada. G. is the seat of Hobart College (1824), and has ten churches, two fine parks, &c. Pop. (1870) 5521.

Généviève (Celtic, 'white wand'), a saint of the Roman Catholic Church, is said to have been born at Nanterre, near Paris, in 422. According to the poetical story of her life, she was first a shepherd-maid of spotless purity and holiness; afterwards removed to Paris, and joined a sisterhood of Christian virgins. When Attila was marching on Paris (451), G.'s prayers were believed to have at least contributed to turn him aside, and when that city was taken by the Franks, she moved the heathen kings Hlodwig and Frederik to treat the Parisians with clemency and to set free many of their captives. G. died in 512, when she was made the chief patron saint of Paris. Her name is a favourite with the Parisiennes. A society of priests, bearing her name, was founded in the 12th c. and lasted till the Revolution. The 'Sisters of St. G.,' an order created in 1636, took no monastic vow, but devoted themselves to teaching young girls, and to the care of the sick.

Gen'ghis Khan, also spelt **Zen'ghis Khan**, but properly **Chingiz Kaan** ('greatest of khans'), a famous Mongol conqueror, whose original name was Temudjin, 'best steel,' was born at Deylun Yeldak, on the Upper Hoangho, January 25, 1155. His father, chief of the tribe Neyrun, dwellers N. of the wall of China, dying when G. K. was thirteen, civil war broke out, and the young prince had to fly to Toghrul Ungh, Khan of the Keraites, whose armies he led so successfully that at length Toghrul, from jealousy, planned his assassination. G. K., however, escaped to his native country, raised an army, and made himself master of Toghrul's dominions. In 1204 he defeated the tribe of the Naimans, and in 1205 received the title G. K. or Chingiz Khan, as the acknowledged chief ruler in Mongolia. He had already projected the invasion of China, with which design he published his great code, and enforced strict discipline through his troops. After five years of war with rebellious Mongol chiefs, he fell upon N. China, and though his career of conquest was stayed for a time by a treaty, and by his marriage with the Emperor of China's daughter, in 1215 he seized Pekin and annexed the N. provinces of China. Having now united the Mongols under his single sway and subdued E. Asia, he attacked Mohammed Kothbeddin, who held a sultanate stretching from the Indus to the Black Sea. Mohammed was defeated near the Jaxartes (Scidaria) in 1218, and his realms devastated by G. K.'s followers, who now, under various generals, conquered Persia, advanced into the plains of India, and swept over Europe as far W. as the Dneiper. In 1224 G. K., who had ravaged the fairest regions of Central Asia, spilt the blood of 5,000,000 of men, and formed an empire stretching from the Black Sea to the Sea of Okhotsk, returned to his capital of Kara-Korum in the N. of Mongolia, from which he had been absent seven years. But his thirst for conquest was still unslaked. In 1225, though he was above sixty years of age, he led a horde of fierce nomads across the desert of Gobi, in the depth of winter, and overthrew the King of Tangut. He then descended on S. China, but after taking Nankin and other cities, died in the full flush of victory, August 24, 1227. His aim was to conquer the whole world, and the design was never, says Sir Rutherford Alcock, nearer its accomplishment than in his lifetime. He was reckless of bloodshed,—according to Mr. Howorth, upwards of 18,000,000 of human beings perished at his hands in China and Tangut alone—but to his subjects he was a considerate as well as a strict ruler. He gave a kind of national and civil organisation to the scattered and lawless tribes of Central Asia, made rigid edicts against crime, and established a great postal system. He was a firm monotheist, but tolerated all beliefs. His empire was

afterwards divided among his four sons. See Howorth's *History of the Mongols* (Lond. 2 vols. 1876), and Douglas's *Life of Jenghis Khan* (translated from the Chinese, Lond. 1877).

Ge'nii, a name given to the Arabic *Jinn* ('the invisible'), from a mistaken belief that the word was cognate with the Latin *genii*, or tutelary spirits. (See GENIUS.) The *Jinn*, belief in whom is enjoined by the Koran, are supposed to have dwelt in the world before the creation of man, but having rebelled against Allah, were expelled to the realm of *Jinnistan*. Though inferior to men in dignity, they are more powerful, and cause much misery and happiness to mortals, visiting the earth in storms and taking whatever form they please, which is generally that of a monster. Many are said to have been converted by Mahommed. The good ones are known as *Peri*. The *Jinn* play a large part in Arabian and Persian fiction, and appear very frequently in the *Thousand and One Nights*.

Genis'ta, a genus of Leguminous plants containing over a hundred species. *G. tinctoria*, found throughout Europe, and common in some parts of England, was formerly extensively used as a yellow dye, and called Greenweed (q. v.) or woodwaxen. *G. Anglica* is another shrubby species found in Britain, commonly called petty whin and needle greenweed. The Plantagenet kings took their name from wearing a sprig of the *Planta genista* as a badge.

Gen'itive, properly **Gen'etive**, one of the cases in grammar. According to the common explanation the G. (Lat. *genitus* from *gigno*) denotes descent from something, as *regis filius*, 'the king's son.' The words *regis* and *king's* are here said to be in the G. case as denoting the son's origin. That this explanation is erroneous will be seen at once by a glance at such expressions as *pueri pater*, 'the boy's father,' *regis domus*, 'the king's house.' A much more rational theory, and more in keeping with the nature of the case, is that offered by Professor Max Müller in his *Science of Language*, and now universally adopted by grammarians. According to his view the G. (Lat. *genus*, *generis*), that is, the *generic* case, defines the class or genus to which anything belongs. Thus in the phrase *regis filius* the G. *regis* distinguishes the *filius* from the *filii* of other parents, and limits him to a particular class, viz., *king's sons*. The G. may stand to the governing substantive in a variety of relations. The relation may be possessive, as *regis domus*, 'the king's house;' attributive, as *regis domus* = *regia domus*, 'the royal house;' or appositional, as *vox gloriæ*, 'the term glory.' Sometimes the G. may represent either the subject or the object. It is then termed the *subjective* or *objective* G. as the case may be. Thus *amor Dei* may either mean 'the love of God to man,' *i.e.*, God's love to man (subjective), or 'the love of God by man,' *i.e.*, man's love of God (objective); *injuria militum*, 'the injury done by' (subjective) or 'to the soldiers' (objective). The relations of the G. case are expressed in English by *'s*, the form being termed the *possessive* case from the frequency with which it indicates possession; by a preposition (generally *of*); or by an Adjective (q. v.). The old theory that the *'s* in English is the pronominal adjective *his* is absurd. For although it may seem to explain such a phrase as 'the king's son,' *i.e.*, the king his son, it really does not remove the difficulty one whit, *his* (*i.e.*, *he's*) being itself the possessive form of *he*. While in such forms as 'the queen's crown,' 'the book's cover,' 'the men's horses,' it utterly fails. It is simply the relic of *es*, the prevalent inflection for the G. singular in Old English, and which in Transition English absorbed all the others.

Ge'nius (Lat. *genius*, from *gigno*, *genitum*), properly the superior or spiritual nature that is innate in everything, was the name applied by the Romans, as *daimōn* was by the Greeks, to the protecting spirit that was supposed to accompany every created thing from its origin to its end. Hesiod estimates the number of the *daimones* at 30,000, and considers them to be the souls of just men who lived in the golden age. On this idea the Greek philosophers framed their elaborate theory of demons. In Pindar the *genethlios daimōn* is the G. who watches over man from his cradle to his grave. The G. was looked on as an emanation from the divinity; and that he must have been in some way connected with Jupiter we infer from the fact that the G. of a woman was called a *Juno*. The genii were frequently confounded with the *Manes*, *Lares*, and *Penates*, to whom they were closely allied in one important feature, viz., the protection of mortals, but from whom they were wholly distinct. A G. was represented as black or white, according as the future of the person of whom he was the guardian angel was dark or fair (Hor. *Epist.* ii. 2, 187-189). The bridal bed (*lectus genialis*) was sacred to the G., who was worshipped on birthdays with incense, flowers, and libations of wine. Not only individuals but places had their G. The image of the national G. of Rome may be seen on coins of Hadrian and Trajan. The G. of a male was represented as a beautiful boy, naked with the exception of a *chlamys* on his shoulders, and furnished with the wings of a bird. A *Juno* (guardian spirit of a female) was represented as a young girl with the wings of a bat or moth, and entirely draped. The G. of a place was portrayed as a serpent eating fruit. See Schömann's *De Diis Manibus, Laribus, et Geniis* (Greifswald, 1840); Ukert's *Ueber Dämonen, Heroen, und Genien* (Leips. 1850). With the Christian writers the G. (*kakodaim n*) is an evil spirit condemned to endless punishment for his pride and insubordination. See DEMONS.

Gen'lis, Stéphanie Felicité Ducrest de St. Aubin, Comtesse de, a French authoress of good family, was born near Autun, 25th January 1746. At an early age she married the Comte de G., and in 1782 was intrusted with the education of the children of the Duc de Chartres, afterwards Duc d'Orléans. At this time she published several works on education, &c., which attracted a good deal of attention. In 1793 she withdrew with her young wards to Switzerland, where she heard that her husband had perished by the guillotine. In 1800 she returned to France, won the favour of Napoleon, who when he became emperor gave her a pension, which ceased on the Bourbon restoration. She continued her literary labours until her death, December 31, 1830. Among her writings are *Théâtre d'Éducation*; *Adèle et Théodore*; *Madame de la Vallière*; *Henri le Grand*, a biography; *Les Chevaliers du Cyne*, an indefensible political work; *Dîners du Baron Holbach*, an attack on the French philosophers of the 18th c.; *Mademoiselle de Clermont*, a tale, perhaps her most popular work; and her *Mémoires*, written when she was above eighty years of age. Madame G.'s character was by no means estimable. She was a voluminous and popular writer, but her works show slight traces of genius. See her *Mémoires* (10 vols. Par. 1825), and Sainte-Beuve's *Causeries du Lundi*.

Gen'oa (Ital. *Genŏva*, Fr. *Gênes*), surnamed *La Superba*, the chief commercial city in Italy, stands at the foot of the Apennines, on the Gulf of G., in the province of the same name, 79 miles S.E. of Turin, with which it is joined by rail. Pop. (1872) 130,269. From the sea G. has a magnificent appearance, its houses rising in tiers up the steep slope of hills, whose barren summits are crowned with turreted forts. The upper city consists of streets of palaces—noble piles with vast halls and marble staircases and terraces, but mostly disfigured by stucco. Many are crumbling away, others are changed into warehouses, but some are still the dwellings of the rich. Among the chief buildings are the cathedral of S. Lorenzo, built in 1100, but which has been greatly altered, and is now partly Romanesque, partly Renaissance, and partly French Gothic; S. Ambrogio, which has many splendid chapels founded by noble Genoese families, and is lavishly adorned with gilding, mosaics, and paintings; S. Annunziata, with fluted columns of red marble and rich vaultings; the Palazzo dei Principi Doria, whose garden has a large *loggia*; the Palazzo Balbi, which possesses an excellent picture gallery, and affords delightful glimpses of foliage through its colonnades; the Palazzo Ducale, which is all of white marble, and was once the abode of the Doges, but is now used as the townhall; and the Palazzo dell' Universitat, formerly the seat of a Jesuit college, but transformed in 1812 into a university, with a library, museum, botanical garden, and the finest court and staircase in G. The finest streets are the spacious Via Balbi and the Via Nuova, which is lined with palaces, many having marble fronts. The Carlo Felice is the chief theatre, and the Acqua Sola, a high park at the N.E. of the city, is the favourite promenade. In the Piazza Acquaverole is a statue of Columbus (q. v.). It was raised in 1862, is all of white marble, and is placed on a pedestal ornamented with ships' prows. The lower part of G. is a maze of narrow, winding, and very steep and filthy lanes and streets, which are partly separated from the harbour by a high wall with arcades and marble platforms. The harbour is semicircular and sheltered by two long piers, the

Molo Vecchio and Molo Nuovo. It is too small for the growing trade, and can with difficulty be enlarged from the very great depth of the water. The manufactures are considerable and various, consisting chiefly of silk, velvets, lace, cotton, candles, soap, and oil. The making of household furniture and filigree work in coral and silver employs a good number of the Genoese, and shipbuilding is an important industry. The imports, of which about one-third is from England and the rest mainly from France and N. America, are valued at 300 million francs annually, and the exports at 120 millions.

G. (the ancient *Genua*) was early famous as a harbour, and in the Roman times had great trade in the products of the Ligurian coasts. It was a Roman *municipium*, and after the breaking up of Karl the Great's empire constituted itself a republic, presided over by Doges. During the middle ages it was commonly known as *Janua*. It carried on a large Levantine trade even before Venice—with which city as well as with Pisa it had fierce and frequent strife (see VENICE)—and rose to its zenith of power and wealth in the middle of the 13th c. The Genoese shared largely in the crusades, and at one time monopolised the traffic with the Black Sea, had a lucrative trade with India, and held many rich possessions in the East. G. was long convulsed by party struggles, begun by the Doria and Spinola families, who were Ghibellines, and the Grimaldi and Fieschi families, who were Guelphs. At last Andrea Doria (q. v.) established an oligarchical government, against which the Fieschi (q. v.) conspired unsuccessfully in 1547. Gradually the city lost its foreign possessions, the Turks seizing its eastern conquests. Corsica, which remained last of all its foreign territories, was annexed in 1797 by the French, who in 1802 captured G. itself. In 1815 the city was added to the kingdom of Sardinia, and now belongs to the kingdom of Italy. See Serra's *Storia della Liguria* (4 vols. Tur. 1834); Canale's *Storia Civile, Commerciale, e Litteraria dei Genovesi* (9 vols. Gen. 1844 54), and *Nuova Storia della Republica di Genova* (Flor. 1862-64).—**Gulf of G.**, a bay rather than a gulf, on the coast of Italy, between Spezia and Oneglia. It is sheltered on the N. by the Apennines, which approach the sea very closely here.

Genouillère, in fortification, the part of the parapet between the ground and the *sill* of the embrasure. It derives its name from being about the height of a man's knee (Fr. *genou*).

Genre Painting (Fr. *genre*, Lat. *genus*, 'kind, variety'), the name of a department of art distinct on the one hand from historical (*genre historique*), and on the other from landscape (*genre de paysage*) painting, but nevertheless given to works in which both historical figures (when they are represented under conditions common in everyday life) and natural scenery (when it assists the composition, but does not preponderate) may be introduced. As this style of painting does not concern itself with strictly historical incidents or historical personages *as such*, it is not regarded as what has been loosely termed 'high art.' On the other hand, although it has been carried perhaps to its highest perfection by the painters of the Dutch school (Ostade, Teniers, and the tavern school generally), it is by no means limited in its range to subjects arising out of 'low life.' The Dutch genre picture, which has familiarised us with the pleasures and pastimes of the Netherlands in a past age, is well known. In the modern English school the name is applied to all compositions with figures, whether interiors or works having a landscape background, all dramatic compositions, and all pictures in which humour is the quality most fully expressed.

Gens (root *gen*, from Lat. *geno*, *gigno*, 'I beget or bring forth') primarily signifies *kin* or lineage. Among the Romans it denoted sometimes a nation or community like *natio* and *populus*, but specially a clan embracing several families united by a common name and by common religious rites. In the Roman constitution and in Roman law the term G. is always used in the latter signification, and the words G. and *gentiles* had thus a special and definite meaning. At first the G. was purely patrician, but after the passing of the *Lex Canuleia* (445 B.C.), which granted *connubium* between patricians and plebeians, plebeian also. Before this, however, some of the *gentes* contained plebeian *familiæ*, though it is by no means clear how they are to be accounted for. According to the Pontifex Scævola (see Cic. Top. 6), those alone were *gentiles* who (1) bore the same name, (2) were born of freemen (*ingenui*), (3) had no slave among their ancestors, (4) had suffered no *diminutio capitis* or reduction to an inferior condition. Of the *diminutio capitis* there were three grades, which it may be convenient to note briefly here. The first (*maxima*) consisted in the loss of personal freedom (*libertas*), and of course the loss of the *civitas*; the second (*minor*), the loss of *civitas*, or of full *civitas* without loss of personal freedom; and the third (*minima*) had reference neither to *civitas* nor *libertas*, but resulted from a change of family. For example, a man who was his own master (*sui juris*), by adoption (*adrogatio*) into another family, became subject to parental control (*patria potestas*). Each G. was composed of a number of *familiæ* or branches, all supposed to be sprung from a common ancestor; each *familia* was made up of individual members. The *gentes* and *familiæ* were thus the social divisions of the original Roman tribes, which were divided politically into *curiæ* and *decuriæ*. Niebuhr argues that the *decuriæ*, or decades, and *gentes* were the same, in which case the G. would be the smallest political division without reference to kindred; but it seems much more reasonable to suppose that the *familiæ* of each G., as well as the individual members of each *familia*, referred their origin, as in the case of the Celtic clans, to which the Roman *gentes* bear a marked resemblance, to a common ancestor, and that all who were *gentiles* were regarded as connected by blood, however remotely. See Niebuhr's *Roman History*; Malden's *History of Rome*; Göttling's *Geschichte der Römischen Staatsverfassung*; Becker's *Handbuch der Römischen Alterthumer*; Wachsmuth's *Die ältere Geschichte des Römischen Staates*.

Gen'seric, or **Gai'serich** ('spear-prince'), king of the Vandals, one of the barbarian leaders who destroyed the Roman empire, was the son of Godigiselus, who founded a Vandal kingdom in Spain. In 429 G. invaded and ravaged N. Africa, taking Hippo in 431 and Carthage in 439. Invited by Eudoxia, wife of the Roman Emperor Maximus, to be her champion against her husband, as Attila had been the champion of Honoria, he fell upon Italy with a motley host of Vandals, Moors, Ausurians, and Mediterranean pirates, sacked Rome in 455, and carried off the chief art treasures of the city in his ships. The Western emperor Majorian sent an expedition against G., which was destroyed in the Bay of Carthagena in 457, and the fleet despatched against him by the Eastern emperor Leo was burned off Bona in 468. G. died at a great age in 477. He was a man of ruthless cruelty, and being an Arian, persecuted the Catholics of N. Africa with terrible severity. See Gibbon's *Decline and Fall of the Roman Empire*, ch. xxxiii.-xxxvi.

Gentia'na, the typical genus of the Corollifloral order *Gentianaceæ* (q. v.). It contains many herbaceous species, with very showy—generally blue—flowers, natives of temperate countries. Almost all the species possess a more or less bitter principle, employed as a tonic. *G. acaulis* is cultivated in British gardens under the name *Gentianella* (q. v.). *G. nivalis*, an annual, is only found in Scotland, where it is confined to the mountains of Perthshire and Forfarshire.

Gentiana lutea.

Medicinal Properties and Preparations of Gentiana.—The active principles of G. are obtained from the dried root of *G. lutea*, a plant collected in the Alps, Apennines, and other mountainous districts of Europe. G. being a tonic bitter, without astringency, is used in cases of pure debility of the digestive organs, or when a general tonic is required. It is administered in *powder*, in doses of from 10 to 40 grains; in *extract*, 10 to 15 grains; in *infusion*, 1 to 2 oz; in *mixture*, ½ oz. to 1 oz.; and in *tincture*, 1 to 2 drachms. Incompatibles—Sulphate of iron, nitrate of silver, and lead salts.

Gentiana'ceæ, a natural order of Dicotyledonous plants, embracing about 70 genera and 500 species. The plants of the order are chiefly herbaceous, very few being shrubby, and are generally distributed both in cold and warm countries, but are

rare in the Arctic and Antarctic islands. The principal property of the order is bitterness. The Buckbean (q. v.) (*Menyanthes trifoliata*), a common British marsh plant, and the Centaury *Erythræa*, belong to the order.

Gentianell'a, the common name generally given to *Gentiana acaulis*, the large blue-flowered gentian cultivated in gardens for edgings, &c.

Gentill'y, a village to the S. of Paris and just beyond the fortifications, in the valley of the Bièvre. It has several charitable institutions, a lunatic asylum (*Bicêtre*), extensive manufactures of wax-candles, buttons, ices, and a trade in timber, charcoal, and forage. Pop. (1872) 8871.

Gen'tleman (Fr. *gentilhomme*, from the Lat. *gens* and *homo*) is a man who belongs to a known family, a meaning which the name partly retains. But it has also a wider signification, for, according to Blackstone, a G. is a student of law or in the university, or one who professes the liberal sciences, or can live idly without manual labour and bear the charge and countenance of a G. In the case of an apportionment of a charitable allowance, a court of equity directed the master to include in the definition of G., 'magistrates, esquires, members of the three learned professions, graduates of the universities, attorneys, surgeons, apothecaries, and *the like*' (*Law Mag.* xii. 202).

Gentlemen-at-Arms (formerly the Band of Gentlemen Pensioners), a corps founded in 1509 as the royal body-guard by Henry VIII. In 1834 William IV. ordered it to be called His Majesty's corps of G.-at-A., and it now consists of a captain, lieutenant, clerk of the cheque, and forty members. The G.-at-A. are only called out on a few state occasions.

Gentoo' (Port. *gentio;* Lat. *gentilis*, 'gentile or foreigner') was the name originally given by the Portuguese, and afterwards by the English, to the inhabitants of Hindustan. The word has now fallen out of use, but has a place in history.

Gentz, Friedrich von, a distinguished German political writer and statesman. Born in 1764 at Breslau, he entered the Prussian public service in 1786. On the outbreak of the French Revolution, he was for a time its enthusiastic defender, but ere long became the most fanatical opponent of all attempts to establish free institutions. Both before and after G. passed from the Prussian to the Austrian service in 1802, he was zealous and influential in stirring up war against Napoleon; it was he who drew up the Berlin manifestoes of 1806 and the Austrian manifestoes of 1809 and 1813, and he was present at the Congress of Paris as first secretary. Soon he was known to Europe merely as the tool of Metternich, and to the policy of reaction he wholly devoted his versatile and brilliant talents. He died suddenly, 9th June 1832. His political writings have been twice published in 5 vols. (by Weick in 1836-38 and by Schlesier in 1838-40), his letters in 1841 (new series 1877), and his diaries (*Tagebücher*) in 1861. See also the valuable *Dépêches inédites du Chevalier de Gentz aux Hospodars de Valachie*, by Count Prokesch-Osten (Par. 1876).

Genuflex'ion (Lat. *genu*, 'knee,' and *flectio*, 'bending'). The common posture in prayer among the Jews was standing (Matt. vi. 5), although they also knelt (Dan. vi. 10), and prostrated themselves (1 Kings xviii. 39). The early Christians used five different postures—standing upright, standing bending forward, kneeling on one knee, and on both knees, and lying prostrate. No distinction was made in language, however, between kneeling and prostration, as in kneeling they supported themselves with their hands on the ground. Kneeling, being always regarded as a token of penitence and sorrow, was more practised by Christians than Jews, as if, from a better knowledge of God, they had a deeper sense of their own unworthiness. This principle ruled the occasions on which they knelt. Kneeling was probably the general posture except on Sundays, and between Easter and Whitsuntide, at which times the standing posture was adopted as a sign of the Resurrection.

Gen'us, a division of animals and plants comprising Species (q. v.) which are nearly related to each other by some strongly marked characteristics. Thus the G. *Mus* includes the species of rats and the species of mice, these animals being closely allied in all points of their structure, and the G. *Aquila* includes the various species of true Eagles (q. v.). In botany, the G. *Rosa* includes the various species of roses, and the G. *Rubus* the raspberry, bramble, and their allies. In naming animals and plants scientifically, after the *binomial* system, first used by Linnæus, we give to each organism two names. The first of these indicates the G. to which the animal or plant belongs, and is hence termed the *generic* name; the second is the name of the species to which the animal or plant belongs, and is known as the *specific* name. The common mouse is thus named *Mus domesticus*, and the rat *Mus rattus;* the golden eagle is the *Aquila chrysaëtos*, and the jerfalcon *Falco gyrfalco*.

Geocen'tric (Gr. *gē*, 'earth,' and *kentron*, 'centre'), an expression in astronomy used in the case of a celestial body when its position and motion are considered in relation to a celestial sphere whose centre coincides with the earth's centre, and whose fixed plane of reference is the ecliptic.

Ge'odes (Gr. 'earthy') are hollow nodules, frequently lined in the interior with quartz, calspar, and other crystals. In Somerset and neighbouring counties they go by the name of *potato stones*.

Geod'esy (Gr. *gē* and *daiō*, 'I divide') is the science of determining by measurement and calculation the size and figure of the earth or of any portion of it. Upon it, therefore, depends the construction of maps and charts, the fixing of artificial boundaries of countries, the determination of the lengths of rivers, mountain chains, &c. The chief difficulties encountered arise from meteorological changes affecting the instruments in use, the unevenness of the ground, the practically spherical form of the surface for smaller, and its recognisable ellipticity for larger, areas. The measurement of the base line and angles (see TRIANGULATION) is of course attended with error; but the great number of triangles, and the probability of the error happening on the one side being as great as its probability in happening on the other, probably render the ultimate error arising from the angular measurements very small.

Geoff'rey de Vin'sauf, an English didactic poet of the reign of Richard I., also known as Galfridus Anglicus. He studied at Oxford and in France and Italy, and was in Rome at the end of the 12th c. His metrical treatise *De Nova Poetria*—the earliest attempt at literary criticism made by an Englishman—was very popular in the middle ages. In it G. advocates a return to the style and measures of classic Latin poetry, and protests against the mediæval rhyming Latin verse. A lively *Itinerary of King Richard* has been ascribed, but probably wrongly, to G.

Geoffrey of Monmouth, also named **Jeffrey ap Arthur**, one of the most famous of English mediæval writers, was born about the beginning of the 12th c. at Monmouth, and educated at the Benedictine monastery of that town. He was made Bishop of St. Asaph in 1152, and died about 1154. G.'s Latin *Historia Britonum* has been one of the most important additions ever made to our literature. It deals with the 'history' of Britain from the times of the Trojan Brut to the death of Cadwallo, relating the wildest fictions with an air of perfect gravity, and, as the author remarks, without tiring the reader by rhetorical ornament; blending mediæval legends with Welsh fancies of past greatness and future victory over the English. The work for the first time introduced into England the tales of Arthur and the Round Table, with which English literature has become so deeply imbued, which so many writers have retold, from Walter Mapes to Tennyson. (See ARTHURIAN ROMANCE.) G.'s pre-Arthurian legends, though much less popular and fascinating than his Arthurian stories, have given many themes to our poets, *e.g.*, the tales of Brut, Ferrex and Porrex, Locrine, and Lear, adapted by Sackville, Warner, Spenser, Milton, and Shakespeare. Although G.'s statement that he translated the book from one Walter Calenius—who has been wrongly confounded with Walter Mapes—was most likely a mere jest, the fabulous chronicle is undoubtedly based on old Cymric legends which had passed into Wales from the Celts of Brittany. The book became at once widely popular, was abridged by Henry of Huntingdon, and recast by Wace and Gaimar. It was first printed at Paris in 1508. There is an English translation by Aaron Thompson (Lond. 1718), which is reprinted in Bohn's *Antiquarian Library*.

Geoff'rin, Marie Thérèse, *née* **Rodet**, a celebrated French patroness of letters, was born at Paris, June 2, 1699. Her station was originally humble, since she was the daughter of a valet; but having at the age of fourteen married a rich trades-

man, she was left on his death with such a colossal fortune as secured her an entrance to the highest circles of Parisian society. Madame G., though without education, was a woman of much natural cleverness, and she succeeded in forming a *salon* of literary and philosophic celebrities without any rival at that day. Diderot, D'Alembert, Marmontel, and Thomas were members of her circle; Horace Walpole, Hume, and Gibbon among her foreign guests; and she so befriended Stanislas Poniatowsky, before he became King of Poland, that he was ever after accustomed to call himself her son. Madame G. contributed largely to the publication of the *Encyclopédie*; and her munificent liberality procured her a wide reputation, not in Paris alone, but all over the Continent. She died in October 1777, and *éloges* upon her were written by D'Alembert, Morellet, and Thomas. Her *Mémoires* were published by Marmontel; her *Correspondance* was edited by Grimm and Diderot; and her *Treatise on Conversation* by Morellet.

Geoffroya, a genus of trees occurring in S. America, belonging to the *Leguminosæ*, but differing from most of that order in having succulent fruits. The principal species is *G. superba*, a magnificently branched tree with beautiful green foliage and bright yellow flowers. Its wood is hard; and its fruit when boiled is said to be largely used by the inhabitants of the Ilha de St. Pedro.

Geoffroy St. Hilaire, Étienne, a French naturalist, was born at Étampes (Seine-et-Oise), April 15, 1772. He first studied for the Church at the Collége de Navarre, after which he went to Paris, where his taste for natural science strengthened under the fostering of Haüy and Daubenton. Through the influence of these he was nominated, at the age of twenty-one, Professor of Zoology in the Jardin des Plantes. In 1798 G. accompanied Napoleon to Egypt, returning in 1801 with valuable collections of natural history specimens. His labours secured his admission to the Académie des Sciences in 1807; and after his return from Portugal, whither he had been sent in 1808 on a scientific mission, he was elected Professor of Zoology in the medical faculty at Paris. As a theorist he maintained a great unity of plan throughout the organic kingdom, a principle which was keenly opposed by Cuvier. His constant endeavour was to establish this theory, which is developed and discussed in all his chief works—*Philosophie Anatomique* (Par. 1818–20), *Sur le Principe de l'Unité de Composition Organique* (Par. 1828), and *Principes de la Philosophie Principe* (Par. 1830). G. died at Paris, June 19, 1844. He wrote numerous and valuable treatises and memoirs the number of which alone indicates the extraordinary energy of his nature. See *Vie, Travaux, et Doctrine Scientifique d'É. Geoffroy St. Hilaire* (Par. 1847) by his son.—**Isidore G. St. H.**, son of the preceding, was born December 16, 1805. He first assisted his father, and in 1841 became Professor in the Museum, and in 1845 General Inspector of Studies. In 1850 he succeeded Blainville in the chair of Zoology in the Faculty of Science, and died November 10, 1861. He early took up the subject of monstrosities, publishing his *Histoire Générale et Particulière des Anomalies de l'Organisation chez l'Homme et les Animaux* (3 vols. Par. 1832-37). Among his other works are *Essai de Zoologie Générale* (Par. 1840); *Histoire Naturelle des Insectes et des Mollusques* (2 vols. Par. 1841); and *Histoire Naturelle Générale des Règnes Organiques* (2 vols. Par. 1854–59).

Geog'nosy (Gr. *gē*, 'the earth,' and *gnōsis*, 'knowledge'), a term much used by German geologists, but rarely met with in English treatises. It designates that branch of Geology (q. v.) which treats merely of observation, or the practical part of the science without any regard to theory.

Geograph'ical Distribu'tion of An'imals. The fact that each country or region of the earth's surface has a fauna or collection of animals more or less peculiar to itself is well known. The investigation of the causes to which the distribution of the various species of animals is due has only recently received the attention which it deserves. The recent work of Mr. Alfred Russel Wallace on *The Geographical Distribution of Animals* (Lond. 1876) is the first philosophical contribution of any importance which has been made to the literature of the subject; while the distribution of the mammalia is the only part of the subject which has been investigated with due precision. The G. D. of A. was formerly explained—by Professor Edward Forbes, among other naturalists—on the *special creation* hypothesis, by supposing that each species of animal was created in a special district or region—named its *specific centre*—and that the form extended its range of distribution to a greater or less extent, according as physical conditions (such as the presence of mountains, lakes, seas, &c., the presence or absence of a due food-supply, &c.) were more or less favourable. It is obvious that this explanation admits of no further elaboration—it is a statement of belief, susceptible of no direct or indirect proof or corroboration. The other mode of explaining the facts of the G. D. of A. rests on the recognition of the truth and feasibility of the Darwinian and other evolutionary hypotheses. The chief facts which the consideration of the subject brings under notice are—(1) That the more remote and distant countries are, the more dissimilar will their animals be, and *vice versa*; (2) that where the animals of two countries are similar or alike, these two countries must at present be, or must in the recent past, have been, in geographical connection; (3) that each species has its definite area, as also has each genus and family; and that locality or distribution is thus as much a characteristic of animal life as the possession of a special structure or other marks of individuality. The near resemblance, for example, seen between the animals of Britain and those of the adjacent parts of the continent of Europe is explicable on the supposition of the recent continuity of the two regions. Similarly, the peculiarities of its fauna which separate Trinidad from the other W. India Islands, and the resemblance of its fauna to that of Venezuela and the adjoining part of the S. American continent, strongly suggest the probability that Trinidad was recently in connection with the S. American region. The faunas of Sumatra and Borneo are alike; that of Java is mostly different from either. Java is nearer to Sumatra than Borneo, and, therefore, the dissimilarity of the Javan fauna is explained by assuming that Sumatra and Borneo have been in connection more recently than Sumatra and Java. On the Darwinian hypothesis, which is founded on the natural tendency of animals to vary, the likeness between the fauna of two near regions is explained on the ground that they have not had time to vary or to spread themselves, and thereby acquire differences. The differences, on the other hand, between the animals of the widely-separated regions are attributed to the great length of time which has elapsed since the regions were in continuity, and which has, therefore, permitted variations and differences to become developed. The fact of the individuals of each species being confined to a certain defined locality is explained by assuming them to be the descendants of ancestors or pre-existing species which inhabited the same area.

Mr. Sclater's zoographical provinces appear to be those which hold good for the entire animal creation, although, as has been remarked, they have as yet been applied to indicate the distribution of only a few groups of the animal world. These provinces are as follows, the characteristic mammals of each region being indicated:—I. PALÆARCTIC REGION, including the world N. of a line drawn S. of the Atlas, and passing E. through the S. of Palestine and Persia, and along the Himalayas, through Central Asia and China to the Pacific. This region has no monkeys, lemurs, or fruit-eating bats; Carnivora (wolves, foxes, gluttons, bears, lynxes, &c.) abound; and Rodents and Ungulata (sheep, deer, &c.) also occur. Neither the elephant nor the hyrax, however, exists. II. ETHIOPIAN REGION, including Africa S. of Atlas and Arabia up to the Persian Gulf and Madagascar. The characteristic mammals are the highest apes, the African elephant, hyrax, rhinoceros, hippopotamus, wart-hog, antelope, giraffe, and manis, but no bears. Madagascar and the Mascarene Islands are sometimes regarded as forming the (II. *a*) LEMURIAN SUB-REGION, and are distinguished by the prevalence of lemurs and the absence of Felidæ and Ruminants. III. INDIAN REGION, including Asia S. of the Palæarctic Region and the E. Archipelago, down to Wallace's line—a line running between the islands of Bali and Lombok to the S., and Borneo and Celebes to the northward. Here are found the orang and other monkeys, flying lemurs, tigers, leopards, &c., the Indian elephant, Malayan tapir, rhinoceros, and the manis. IV. NEARCTIC REGION, including America down to the Isthmus of Tehuantepec. This region contains mammals resembling those of the first region, and which have probably come from the W.; *e.g.*, bears, beavers, sheep, and deer are found, but the prong buck, musquash, and pouched mice are peculiar. The racoon and opossum probably originated here. V. NEOTROPICAL REGION, comprising America S. of Tehuantepec. The monkeys are those of the families *Cebidæ* and *Hapalidæ* (spider monkeys, &c., and marmosets);

vampire bats exist, but no fruit-eating bats; porcupines are plentiful; the opossum, sloth, armadillo, ant-eater, Insectivora, civets, and tapirs occur; but there are no elephants. The (V. *a*) ANTILLEAN SUB-REGION has a few mammals, but these are peculiar (*Solenodon*, *Capromys*, &c.). VI. AUSTRALIAN REGION, including Australia, New Guinea, and the Moluccas up to Wallace's line. No higher mammals are here found native, except a few rodents and bats, the Australian territory being the home of the Didelphia and Ornithodelphia—kangaroos, Ornithorhynchus, Echidna, &c.

Geographical Distribution of Disease, also called **Medical Geography** and **Noso-Geography,** is that branch of medical science which treats of the manner and conditions under which diseases are distributed over the globe or confined to certain districts. The science is thus intimately connected with physical geography and vital statistics. The geographical limits of particular diseases and their regulated distribution frequently depend upon atmospheric influences, such as temperature, moisture, density, and electricity, and upon telluric influences, such as geological formation, topographical situation, elevation of the soil, vegetation, drainage, and cultivation. Such diseases depend in great measure, both in origin and propagation, on the manners and customs of the inhabitants, their position in civilisation, and their attention to personal and general hygiene. There are certain diseases peculiar to localities which are not found elsewhere, and certain miasmatic diseases of an infectious type, as yellow fever, plague, enteric fever, typhus fever, and cholera, which have particular climates or zones where each predominates, and beyond which they rarely pass, and they may thus be arranged systematically in zones of distribution N. and S. of the equator, bounded in great measure by isothermal lines, approaching to but not identical with the degrees of latitude. (See ISOTHERMS.) In countries under the line of the equator of greatest heat, where the mean temperature is 82° F., malarial fevers, yellow fever, cholera, dysentery, diarrhœa, and hepatic affections attain their maximum intensity; but each of these diseases has its peculiar habitat, within this circumscribed area, depending upon local causes. Cholera is endemic in certain parts of British India, yellow fever on the shores of the Gulf of Mexico and the Antilles, and malarial fevers in flat low-lying countries, the vicinity of marshes, lakes, and rivers, more especially where there is a damp argillaceous or ferruginous sub-soil. A certain amount of heat and moisture is necessary for the development of certain maladies in intertropical regions; and the period of disease follows the course of the sun, the unhealthy season occurring at opposite times on the N. and S. of the equator. Cholera and yellow fever frequently move out of their endemic areas as virulent epidemics, but the range of the latter is more circumscribed than that of the former, for with a temperature under 55° F. its persistent existence and propagation become impossible.

Within the temperate isothermic zone the varied forms of continued febrile disease take the place of the malarial fevers of the tropics; but as we approach the tropics the continued form merges into the intermittent type. This zone is the most healthy in the world, the prevailing causes of ill-health being mainly due to condensation of population, vicious modes of life, and inattention to personal and general hygiene; but within it nearly every type of disease is represented as it embraces the extremes of temperature of the torrid and frigid zones. The diseases which furnish the greatest mortality are the zymotic and constitutional. Typhus and enteric fevers are endemic, more especially between 30° and 40° N. lat.; measles, scarlatina, whooping-cough, diseases of the respiratory organs, and rheumatism prevail everywhere; intermittent and remittent fevers occur in Sweden and Italy; pellagra in Italy, France, and Spain: plica polonica in Poland and Tartary; leprosy and elephantiasis are met with in Scandinavia.

The prevalent diseases of the polar isothermic zone are asthmatic and catarrhal affections, influenza, scurvy, erysipelas, diseases of the skin and digestive organs. The majority of the natives of Greenland, Labrador, and Iceland die from asthmatic and catarrhal affections before the age of fifty.

There is a distinct connection between the geological nature of the soil and certain pathological conditions of man by means of which diseases existing in one place may be predicated as existing in another. Goitre and cretinism are endemic in the Alps and Pyrenees, and it was predicated that the same diseases would be met with in the Himalayas and Cordilleras. Experience verified the prediction. Probably many of the diseases peculiar to particular localities depend more upon deleterious ingredients contained in the water supply than upon any direct telluric influence.

The first important communication on the G. D. of D. was made by Alexander Keith Johnston, F.R.S.E., see *Trans. Epidem. Society* (Lond. 1856). The most important works are Mühry's *Outlines of Noso-Geography* and Boudin's *Traité de Géographie et de Statistique Médicales Endémiques* (Par. 1857). See also Sir Ranald Martin's work on the *Influence of Tropical Climate;* Inspector-General Lawson's *Observations on the Influence of Pandemic Waves in the Production of Fevers and Cholera,* and article on PANDEMIC WAVE THEORY OF DISEASE.

Geographical Distribution of Fossil Animals. See PALÆONTOLOGY.

Geographical Distribution of Plants. The causes which determine the distribution of plant life throughout the globe are numerous and varied. The influences exercised by climate, the geological changes and configuration of a continent, and the fitness of the plants themselves to carry on the struggle for existence, are the great factors. Schouw enumerates twenty-five phyto-geographical regions.

1. Alpine Arctic Flora. Here are met with the most northern limits of vegetation in the form of mosses and lichens, grasses, sedges, willows, saxifrages, gentians; and caryophyllaceous plants, remarkable for their neat style of growth and the size and beauty of the flowers as compared with the low habit of the plants that bear them, are seen. Forests of birch and fir also occur. There are no cultivated plants in this region, which embraces all the land within the Arctic circle, together with some tracts which lie external to it, and the summits of the loftier mountain ranges of Europe.

2. The region of umbelliferæ and cruciferæ is characterised by the abundance of the above-named orders, together with the cichoraceæ and cynarocephalæ. Ranunculaceæ, amentiferæ, coniferæ, carices, and fungi are plentiful. The various cereals are cultivated, as also are the potato, buckwheat, leguminosæ, fruit-trees, and vegetables common to the remainder of Northern Europe not included in the first region.

3. The region of labiatæ and caryophyllaceæ, comprehending S. Europe, N.W. Africa, the Azores, and Canaries. Here we meet with salvias and scabiosæ, sempervivums and euphorbiaceæ, evergreen trees, and some more tropical plants—as the date-palm. The castor-oil, oleander, and aloe are seen; rice, millet, figs, olive, cotton, and oranges are cultivated.

4. The region of asters and solidagos includes the eastern part of N. America. Oaks, firs, and vacciniaceæ are abundant; cruciferæ, umbelliferæ, cichoraceæ, and cynarocephalæ are scarce. The genus *erica* is absent. In the northern part there is no cultivation; in the southern agriculture is similar to that in the second region, but maize prevails to a greater extent.

5. The region of magnolias, the southern parts of N. America. Many tropical forms - anonaceæ, sapindaceæ, melastomaceæ, acaciaceæ, zingiberaceæ, cassias, and laurus. Plants cultivated as in the third region. In the Californian and Oregon districts many showy annuals are found, and interesting coniferæ.

6. The region of ternstrœmiaceæ and celastraceæ comprises Japan, N. China, and Chinese Tartary. Peculiar coniferæ abound. Bananas, palms, cycads, camellias, the Indian fig, and the tallow-tree (stillingia sebifera) are seen. Tea, melons, oranges, shaddocks, loquats, peaches, apples, rice, and the cereals are grown.

7. The region of zingiberaceæ, or India generally and Ceylon. Coco-nut, cotton, indigo, opium, turmeric, clove, and pepper occur and are cultivated, along with coffee, bananas, guava, and sugar-cane. The region of Cochin China and Southern China presents many peculiar features. Here we meet with the rice-paper plant, the lorgan and litchi, bamboos, orchids, and caoutchouc-yielding trees.

8. The region of tree rhododendrons, the Alpine district S. of the Himalaya. In the lower parts tropical forms appear; as we ascend, coniferæ, rhododendrons, oaks, &c., are met with. Some European grains and fruit are cultivated.

9. The region of the Asiatic islands, Polynesia. In Sumatra the curious rafflesia is met with; orchids and Australian forms

are seen. Breadfruit, casava, nutmeg, camphor, and the cultivated plants are similar to those of the Indian region.

10. The region of Upper Java and the islands, which rise from 5000 to 12,000 feet above the sea-level, have a flora somewhat similar to that of the mountains of India (8). The tea order, oaks, and thibaudias are seen.

11. The Polynesian or Oceanic region, which includes the tropical islands of the Pacific, has a flora allied to the Asiatic and Australian. Arums, dioscoreas, ferns, boehmerias, gourds, and species of morus are met with. The breadfruit-tree, coco-nut, double coco-nut (lodoicea), yams, plantain, kava, and cabbage-palm are cultivated.

12. The region of amyridaceæ. Here we meet with gum-yielding leguminosæ and shrubs producing aromatic resins—as boswellias. This district corresponds to the floras of Arabia and Persia. Stone-fruits, coco-nut and date-palms, maize, millet, rice, coffee, cotton, ginger, and indigo are cultivated.

13. The desert region of Africa and N. Arabia. Cultivation is confined to the valley of the Nile and oases, where we find the date and doom palms, wheat, barley, and the S. European and Indian grains.

14. The region of tropical Africa, from between the parallel 15° and the tropic of Capricorn, excepting Abyssinia. Members of the sterculiaceæ, as the baobab and kola are found in Senegal. We also meet with species of elais yielding palm-oil, the Calabar bean, and welwitschia. Towards the E. coast there is a more peculiar flora, which perhaps is most specialised in Madagascar. Here are found the sanglimia or ordeal bean, the lattice-leaf plant (*Ouvirandra*), and traveller's tree (*Urania*). Maize, rice, Guinea corn, millet, yams, cassava, banana, mango, pine-apple, coffee, sugar, cotton, ginger, cardamoms, earth-nut, and oil-palms are grown.

15. The region of cactaceæ and piperaceæ. These are specially abundant in Mexico. New Grenada, Guiana, and Peru. The ivory-palm and Victoria regia grow here, as also do leguminosæ, melastomaceæ, cinchonaceæ, orchids, and ferns. The cultivated plants are maize, Guinea corn, cassava, yams, batatas, arracacha, arrowroot, custard-apple, guava, tamarind, chocolate, vanilla, coffee, sugar, cerennial cactus, capsicum, cotton, earth-nut.

16. The region of the highlands of Mexico, that is, districts more than 5000 feet above sea-level, is remarkable for its coniferæ and species of mirabilis, zinnia, and dahlia.

17. The region of cinchonas, which are peculiar to this region. On the Andes we also find the wax-palm (*Ceroxylon*). On the more elevated parts the potato and quinoa are grown, and in the lower coffee and maize. This district extends from 5000 to 9000 feet above the sea-level in the mountainous parts of the Andes.

18. The region of escallonias and calceolarias, including that part of the Andes over 9000 feet above sea-level. Alpine plants occur here, as saxifrages, gentians, carices, grapes, and compositæ.

19. The W. Indian region comprehends the Antilles. Tropical fruits are abundant, and cultivated as in the Mexican region (15).

20. The region of palms and melastomads is that part lying E. of the Andes between the equator and tropic of Capricorn. Vellozias and lychnophoras are seen. The forest vegetation is extremely luxuriant; tillandsias, gesneras, bignonias, cover the trees, as also do wondrous epiphytical orchids; and fuchsias, compositæ, gigantic leguminosæ, ficus, and laurus are prevalent. The cultivated plants are the same as those in the 15th region.

21. The region of arborescent or shrubby compositæ corresponds to the lower basin of La Plata and the plains W. of Buenos Ayres towards Chili. The habit of the compositæ and the natural order calyceraceæ characterise this region. The Chilian flora itself resembles that of New Zealand, Australia, and the Cape, in its proteas, araucarias, and goodenias. Calceolarias, escallonias, and buddleias abound. There are also curious coniferæ. European plants are cultivated here.

22. The Antarctic region includes the countries near the Straits of Magellan. Here are met with Polar plants corresponding to those seen in the Arctic region. Saxifrages, gentians, and primroses, veronicas, pernettias, and empetrum rubrum are found. There are a few British plants. The fuschia, the tussac grass and bolax glebaria or misery-ball are seen. Species of beech and drimys winteri are found. There is no cultivation.

23. The region of mesembryanthemums and stapelias, a S. African flora, extends from the Tropic of Capricorn to the Cape Coast. Ericaceæ are very abundant. Geraniaceæ, Cape bulbs, as ixias, &c., proteaceæ, iridaceæ, acacias, aloes, euphorbias, and leguminosæ occur. Various plants introduced by the colonists are cultivated, as also are yams, plantains, guava, and shaddocks.

24. The region of epacridaceæ and eucalyptia, a flora of Australia and Tasmania. The eucalypti or gum-trees give a peculiar aspect to the country from their vertically-placed leaves. There are many remarkable coniferæ, as the various species of calitris, dacrydium, and araucaria. Proteaceæ, casuarineæ, acacias, compositæ, leguminosæ, stackhousiaceæ, and tremandraceæ abound. Some of the trees rival the wellingtonias of California. The various European plants and grains are cultivated, and in many cases are establishing themselves and taking the place of the original vegetation.

25. The region of New Zealand contains many peculiar coniferæ species of podocarpus and dacrydium. Epacridaceæ, umbelliferæ, and scrophulariaceæ are found, together with a great number of ferns and tree-ferns. The native phormium or New Zealand flax and many introduced European plants are cultivated.

These twenty-five regions may again be further subdivided into smaller districts. In this way we find that various valleys, mountains, and tablelands have special floras. Some plants are only to be found in one particular spot, while others follow the footsteps of man and are almost cosmopolitan. The destruction of forests has affected the prosperity of countries materially by rendering the climate less humid until so little rain fell that vegetation generally became impaired, as in the Mauritius and Azores; and again, the growth of trees, as in Australia, by increasing the rainfall has altered what was almost a desert into a fertile plain.

Geog'raphy (Gr. *gē*, 'the earth,' and *graphō*, 'I write'), a name literally meaning a description of the earth. In its highest sense G. is the science that deals (1) with the earth as a planet, or member of the solar system; (2) with the cosmical distribution of its surface into areas of land and water; (3) with its natural phenomena and their dependence upon physical laws; and (4) with the political and arbitrary division of its surface. A comprehensive view of G. entitles it to be defined as the science of the organic and inorganic life of the earth and of the reciprocal relations of the constituent parts of that life. When geodesy, geology, zoology, and ethnography have done their special work, it then remains for G. to gather and group the results together, and from their conjunction to explain more completely the action of each of the natural sciences that it thus embraces. And as it is an indisputable fact that the character of a nation is developed or modified by conditions of locality, climate, and the structure of a country, so G. comes to have an historico-philosophical side and to hold a definite relation to the history of civilisation.

The science is commonly divided into the three departments of astronomical, physical, and political G. The first of these, dealing with the figure, magnitude, and density of the earth, is treated at length in the articles. EARTH, and LATITUDE AND LONGITUDE. The aspects of physical G. are dealt with in such articles as ATMOSPHERE, CLOUDS, CURRENTS, EARTHQUAKES, GEOLOGY, GLACIERS, RIVERS, SEAS, SEASONS, VOLCANOES, WINDS, &c. Political G., mainly relating to the arbitrary allotment of countries among various Governments, is fully illustrated in articles on the different states, kingdoms, and empires.

The *history* of geographical discovery will serve to outline the growth and scope of the modern science. Among the earliest records incidentally tinged with G. are the Pentateuch and Book of Joshua, which contain frequent and singularly correct reference to contemporary Egypt and Arabia. Homer represents the earth as the shield of Achilles surrounded by the sea, and describes for the first time 'the isles of Greece.' In 568 B.C. Anaximander of Miletus is supposed to have invented geographical maps. Herodotus (born 484 B.C.) may fairly be regarded as the father not only of history but of G., his work describing minutely the various countries he had visited in his wide travels. The world of Herodotus extends from the Red Sea or Indian Ocean to the amber-lands of the Baltic, and from the Atlantic to the W. boundary of Persia. In the 4th c. B.C. the victories of Alexander the Great opened up the path to Northern and Eastern Asia, about the same time that Pytheas

of Massilia (modern Marseille) was sailing along the E. coast of Britain into the Northern Ocean as far as Thule (supposed to be Iceland), and returning by the Baltic, where he heard of Goths and Teutons. Eratosthenes (born 276 B.C.) tried to base the construction of maps on mathematical principles, and invented the parallels of latitude and longitude. His work on G. is lost, but from Strabo we learn that he regarded the world as a sphere 'revolving with its surrounding atmosphere on one and the same axis, and having one centre.' Many large works on G. which are lost were written during the 200 years that elapse till we come to Strabo (born 66 B.C.), whose great work, giving an account of his travels in Egypt, Palestine, Syria, &c., is singularly accurate and interesting. G. made vast strides under the Romans, who carefully took account of the material resources of every conquered territory. A survey of the empire, begun by Julius Cæsar and completed by Augustus, gave descriptions and measurements of each province by the greatest living geometricians. The *Historia Naturalis* of Pliny, containing a digest of the works of Sallust, Cæsar, Tacitus, &c., together with results of his own travels in Spain, Gaul, Germany, and Africa, shows the great increase of geographical knowledge that had taken place. Here there is mention of the Scandinavian lands and of Arctic regions, of settlements in various parts of Africa, of the course of the Niger, of the *island* of Ceylon, &c. The *G.* of Ptolemy embodied the latest contributions to the study of G. in ancient times, and remained the acknowledged canon during the middle ages. In the 8th c. the Arabs eagerly seized upon the study of G., and towards the end of the middle ages a great accession of knowledge resulted from the travels of the Venetians, Genoese, and Portuguese. The works of Carpini (q. v.), Marco Polo (q. v.), and Sir John Mandeville (q. v.) first gave information regarding Central and Eastern Asia. Then followed the discovery of America (q. v.) in 1492, and the doubling of the Cape of Good Hope by Vasco da Gama in 1497. In the 16th c. took place the remarkable Arctic expeditions of Willoughby, Frobisher, and Davis, while one of the earliest works on G. appeared in Sebastian Franck's *Weltbuoch* (1534). Other geographers of the period were Sebastian Münster, Ortelius, Cluver, and Merian. The discoveries by Tasman (q. v.) and Van Diemen (q. v.) in Australasia were greatly extended by those of Cook in the 18th c. Meantime the sciences had been enlisted in the service of the study, and physical G. had been founded by Bergmann (died 1787). 'Comparative G.' itself was raised to the dignity of a science by the labours of Karl Ritter (q. v.). The 19th c. has witnessed the discovery of the Antarctic continent in 1840, the opening up of the African interior by the explorations of Barth, Burton, Speke, Vogel, Livingstone, Stanley, Schweinfurth, and Cameron; the investigation of Central Australia (q. v.); the survey of Central Asia by the Russian Government; the appearance of such works as those of Burnes, Vansberg, Schuyler, &c.; and the Arctic expeditions of various Governments. (See ARCTIC OCEAN and POLAR VOYAGES.) Geographical Societies were established at Paris in 1821, at Berlin in 1828, at London (the most important) in 1830, at Frankfurt in 1836, at St. Petersburg in 1845, at Darmstadt in 1845, at New York in 1852, at Vienna in 1856, at Geneva in 1858, at Leipsic in 1861, at Dresden in 1863, at Kiel in 1867, at Florence in 1867, &c. In 1876 a geographical conference was held at Brussels, at which a scheme was projected for the national endowment of exploration in Africa.

For the history of G. see the works of Malte Brun, Humboldt, Ritter, Peschel, and Löwenberg. Among the best bodies of G. are the *Handbuch* by Gaspari, Hassel, Gutsmuths, and Ukert (23 vols. 1819-31) and the works of Stein (new ed. by Wappäus, 11 parts 1850-71), Ritter, Berghaus, Roon, Klöden, *Erdkunde*, new ed. 1874-77), Daniel, Ungewitter, Cannabich, &c. Cartography has been carried to great perfection in the atlases of Stieler, Johnston, Kiepert, Ravenstein, Berghaus, and Spruner. Of many admirable journals are those of Behm and Wagner, Petermann's *Mittheilungen*, and the *Geographical Magazine*.

Geology (Gr. *gê*, 'the earth,' and *logos*, 'doctrine') is, in its modern signification, the science which treats of the structure, surface configuration, and composition of the earth, of the causes which influence these, and which have brought them to be as they are, and of the structure and history of the once living beings whose remains are left imbedded in its crust. In the early cosmogonies of the Hindus, Chinese, and Egyptians some of the more evident geological operations, such as the alternate submersion and emersion of dry land, earthquakes, volcanoes, &c., are recognised, but only for the purpose of explaining the origin of the earth. According to Herodotus, the Egyptian priests regarded Lower Egypt as the gift of the sea. The Greeks probably borrowed much of their knowledge from Egypt and the East. Anaximander (born 610 B.C.), a pupil of Thales, is said to have been the first to write a philosophical treatise on G., of which there is now no trace. According to Plutarch and Eusebius, he taught that man was not originally created in an adult state, and must therefore have depended for nourishment in the first instance upon some lower animal—foreshadowing in a vague way the modern theory of evolution. Pythagoras (about 580 B.C.), if we may judge from the doctrines ascribed to him by Ovid, seems to have established a system far more philosophical than any before his day. He taught that the total quantity of matter in the world was constant, that sea became land and land sea, and that valleys were formed by the wearing action of running water. The same ideas of continual change and fluctuation are found in Aristotle's *Meteorologica*, and the same philosopher in his discussion of respiration distinctly mentions fossil fishes. The last of these ancient geologists is Strabo, who flourished under Augustus in the beginning of the Christian era. In the second book of his geography he discusses the explanations which had been given of the occurrence of sea-shells high up on dry land. Xanthus the Lydian had ascribed the emersion of land to long-continued droughts; and Strato to the emptying of an inland sea, gradually raised in level through the deposition of mud brought down by rivers upon its bottom, till in the end it forced an outlet into an adjacent body of water. Dissatisfied with these, Strabo enunciated his own theory, that the land, not the sea, was subject to changes of level. He also studied the nature of volcanoes, regarded them as safety valves, and recognised in Vesuvius an extinct crater, although in his day there was neither record nor tradition of an eruption. For fifteen centuries after the time of Strabo, science was practically unknown in Europe; and among the Arabs G. was not cultivated with any great success. In the 10th c. Avicenna, a physician, wrote a treatise *On the Formation and Classification of Minerals*, and Omar El Aalem ('the learned') was persecuted and forced into voluntary exile for having represented the sea as receding and leaving the land dry, a theory which was held to be contradictory to the Koran. Early in the 16th c. G. revived in Europe. In Italy a sharp controversy sprang up regarding the nature and origin of the Apennine fossil shells. The celebrated Leonardo da Vinci maintained that these remains, and the gravel of rounded pebbles found at various heights, conclusively proved the presence and action of water at those localities. In 1517 Fracastoro clearly showed the absurdity of attributing the shells to some 'plastic force' or to the Mosaic deluge, which he argued was far too transient, and could not have buried them at great depths in the heart of mountains. His cogent arguments were unconvincing in an age of superstition, which rather accepted such fantastic theories as those of Mattioli and Fallopio, who imagined the remains to be the result of fermentation. Cardan (1552), Palissy (1580), Colonna (1592), Majoli (1597), and others, supported the sounder views of Fracastoro, mixing, however, much error with truth. For a century the controversy raged, and the organic origin of fossils was generally allowed only after the publication of the works of Steno (1669) and Scilla (1670). The former, a Dane, but long resident in N. Italy, showed the specific identity of the Tuscan fossils with living Mediterranean forms, and declared that he had proof that the country had been twice submerged. Theologians now entered the field, and roused a controversy which lasted a century and a half. Fracastoro had long before shown the physical impossibility of the diluvial theory of the origin of the Apennine shells, and yet to the Deluge were the fossils attributed by the Church generally, and indeed were regarded as proving the truth of the Mosaic narrative. To reject this dogma was equivalent to disbelieving the whole Scriptures. The anxiety of naturalists to reconcile their theories with the sacred writings led to hopeless error and confusion. Woodward (1695) referred the origin of all strata to deposition from the chaos of matter produced at the Flood, the fossils settling down into their places according to their specific gravities. Ray, who protested against the diluvial hypothesis, accused Woodward of

inventing facts to harmonise with his theory, since the order of fossils in no way depended on their weights. Another of these early English cosmogonists was Burnett (1690), who gave a picture of the earth before the Deluge, explaining how it enjoyed a perpetual spring before the Flood, which burst through the crust cracked by the sun's rays. The works of Hooke and Ray, on the other hand, exhibit a more philosophical spirit. The latter especially enlarged on surface denudation and the encroachment of the sea. Italian geologists, however, were still the pioneers of progress. Vallisneri (1721) demonstrated by observation that Italy had been wholly submerged for a lengthened period, and that the water had gradually subsided. Spada of Grezzana (1737), Mattani, and others powerfully resisted the diluvianists, and prepared the way for Lazzaro Moro (1740), who recognised in earthquakes and volcanic eruptions a grand agent in the formation of continents. His doctrine he supported by solid arguments, such as the existence of faults and dislocations. He was, however, much hampered by the accepted age of the world, and he fell into evident error in attributing *all* strata to volcanic ejection. Buffon (1749) developed the theory of Leibnitz (1680), that the earth was originally of volcanic origin, and that Stratified rocks were formed subsequently by the deposition of the waste produced on the nucleus by the denuding action of a universal ocean. G. now began to occupy a prominent place in Germany. Lehman (1756), a mineralogist, divided mountains into three classes—those formed originally with the globe, those produced by a general revolution, and those produced by local revolutions. Two years later, Gesner of Zürich published a treatise on petrifactions. He discussed the filling up of lakes and seas by sediment, the effects of earthquakes, the retreat of the sea, and calculated from observed data that it would require 80,000 years to raise the Apennines to their present height. In 1760 John Michell, Professor of Mineralogy at Cambridge, anticipated many of the theories in stratigraphical G. established forty years later by William Smith. His papers were not published at the time, otherwise they would have certainly formed an era in the history of the science. Turning again to Germany, we find Raspe (1763) discussing with a philosophical fairness the doctrines of Hooke, Ray, Moro, and others, and indicating many of the obscurer problems in G., such as the former tropical climate of Europe and the changes in the typical species. Fuchsel (1762–73) recognised the differences in character and age of several groups of strata, referring their derangement from the horizontal to oscillations of the ground subsequent to their deposition. In 1775 Werner, Professor of Mineralogy at Freyberg in Saxony, by pointing out the great importance of G. in the art of mining, gave a grand impulse to the study of the science. His lectures on the subject roused to enthusiasm his hearers, who soon spread the fame of Werner's school far and wide. He carefully examined the rocks in his own vicinity, tabulated them according to their mineralogical character, propounded a theory for their origin, and generalised this theory to apply to *all* strata throughout the world. He regarded all formations as having been deposited on the bed of a universal ocean, which had now subsided. His disciples accepted his hypothesis *in toto*, and wherever they went strove to reconcile observed facts with it. They received the name of Neptunists or Wernerians. Their doctrines were powerfully combated by the French geologists Desmarest and Dolomieu. The former executed an admirable geological map of the volcanic district of Auvergne, and the latter maintained the volcanic origin of the rocks of Southern France. The controversy thus provoked between the Neptunists and Vulcanists was carried on with an almost unprecedented bitterness, and extended even as far as Scotland, where Hutton was laying the first foundations of his theory. Meanwhile Pallas and De Saussure were prosecuting their philosophic travels—the former in the dreary *steppes* of Northern Russia and among the recent strata bordering on the Caspian Sea, the latter studying the glaciers and highly-contorted formations of the Alps and Jura. Hutton's *Theory of the Earth* was published in 1795, and it forms a marked epoch in the progress of G. The most striking points advanced by Hutton were the constant denudation of the earth's surface and the consequent formation of valleys by running water, the deposition of this waste on the bed of the ocean, the subsequent upheaval of the bed by volcanic action, and the igneous origin of whinstone and granite. In 1797 Playfair published his *Illustrations of Hutton's Theory*, and in the succeeding year Sir James Hall proved by laboratory experiments one of Hutton's positions, that molten rock may give rise to lava or to basalt according to the pressure under which the cooling takes place. While the Wernerians and Huttonians were engaged in their fierce controversy, William Smith, an English surveyor, was establishing the bases of stratigraphical G. His *Tabular View of the British Strata* was published in 1790, and was followed in 1815 by his geological map of England—a work which well earned for its persevering author the title of the 'father of British G.' He classified all the strata now known as the Secondary formations, grouping them according to their fossil contents. The Tertiary formations were similarly treated by the French naturalists Cuvier and Brongniart, whose joint work *On the Mineral Geography and Organic Remains of the Neighbourhood of Paris* (1808) may be regarded as having laid the foundation of Palæontology (q. v.), a growingly important branch of G. By this time a new school of G. was rising, whose votaries preferred to simply amass facts rather than excite controversy by advancing theories. The Geological Society of London, established in 1807, did much to foster this reform, encouraging pure observation, and affording a means by which geologists could become easily acquainted with the labours of others. The example set by London was followed by Paris in 1830, by Dublin in 1832, and by Edinburgh in 1834. The Huttonian and Wernerian struggle gradually died out, but was succeeded by the milder controversy between the Convulsionists and Uniformitarians. The former maintained that the configuration of the surface of the earth, the rugged peaks and gorges, the distorted strata, &c., were produced by sudden throes or convulsions; while the latter, of whose views Lyell was the great exponent, argued that contortion did not necessitate suddenness, and that a gradual but continued movement was quite able to produce the most irregularly-contorted appearances if only sufficient time be granted. The position taken at present by the majority of geologists is intermediate to these, inclining rather to the Uniformitarian side. It is impossible to do more than touch upon the great advances during the last half century. Since William Smith's time the whole series of primary formations has been opened up by men whose names are still fresh in the memories of the present generation. We have had Hugh Miller revealing the treasures of the Old Red Sandstone, Murchison unravelling the mysteries of the Silurian, and more recently Logan attacking the wide unknown deposits of the still more ancient Laurentian in N. America. Sedgwick, Von Buch, Elie de Beaumont, De la Beche, Delauny, Daubeny, Humboldt, Agassiz, Buckland, Lonsdale, among others, are names well known to the student of G. The services which Sir Charles Lyell has rendered to the science are inestimable. The theory of evolution, which received such an impulse from the publication of Darwin's *Origin of Species*, was accepted by the majority of naturalists as affording a philosophical explanation of the succession of life exhibited in the fossils imbedded in the earth's crust. The Uniformitarians, headed by Darwin, Huxley, and Lyell, urged that the agents at work now were the same as had been at work countless ages back, and as will be at work for countless ages to come; that the evolution of species, genera, orders, and kingdoms from the primordial germ must have proceeded by the gradual accumulation of countless variations through a practically infinite time, and that three hundred millions of years would cover a comparatively short geological period. This doctrine received its deathblow at the hands of Sir William Thomson, who, upon physical grounds, demonstrated that one hundred millions of years ago the earth, if it existed at all, would have been a globe of molten red-hot liquid, utterly incompatible with the existence of life. The geologists calculated their time from the thickness of geological strata, assuming the rate of deposition in past time to be equal to the present rate—an unwarrantable assumption. Sir William Thomson based his calculations on two distinct and undisputed facts, namely, the tidal retardation of the earth, and the fact that the earth is a cooling solid. There is a growing disposition to accept Thomson's theory, and this has shown itself in a recent endeavour to rearrange the order of formations, taking account of the possible contemporaneity of unlike strata. Thus the lacustrine Cambrian may be contemporaneous with the marine Silurian, the Permian with the Jurassic, the Miocene with the Cretaceous, &c., the different characters of these conjoined groups being referable to the varying conditions under which they were deposited. G., in its several divisions, is continually touching upon other branches of science. Mine-

ralogy (q. v.) is allied to chemistry and mathematics, palæontology to botany and zoology, physical geography to meteorology and the wide subject of natural philosophy. The principal works on G. are Lyell's *Principles* and *Elementary Geology*; Ansted's *Geology*; Philip's *Guide to Geology*; De la Beche's *How to Observe in Geology*; Jukes and Geikie's *Manual*; Page's text-books; Geikie's *Life of Murchison*, giving an account of the modern progress of G.; Dana's *Mineralogy*; Nicolson's *Palæontology*; besides the writings of Darwin, Murchison, Mantell, Ramsay, Woodward, and others, on special parts of the subject. See the sub-references of PALÆOZOIC or PRIMARY, MESOZOIC or SECONDARY, KAINOZOIC or TERTIARY.

Ge'omancy (Gr. *gē*, 'the earth,' and *manteia*, 'divination') is an ancient mode of divination by points, marks, or circles drawn on the earth, or by casting pebbles on the ground. G. was practised, as a more recondite science, by the Arabian astrologers, who from earthquakes, rents in the ground, and all manner of rumblings and movements beneath the earth's surface pretended to forecast the future and interpret the divine will. Like other modes of divination, it has long been relegated to the domain of the unscrupulous fortune-teller.

Geomet'rical Progres'sion, in algebra, is a series each term of which bears to the one preceding it a constant ratio. Thus, 1, 2, 4, 8, &c., is a G. P. whose common ratio is 2; and 1, $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{8}$, &c. is one whose common ratio is $\frac{1}{2}$. The general series may be represented by a, ar, ar^2, ar^3, &c., where a, the first term, is any algebraic quantity, integral or fractional, positive or negative, and r, the common ratio, any other algebraic quantity. To sum such a series, *i.e.*, to find

$$S = a + ar + ar^2 + ar^3 \ . \ . \ . \text{ to } n \text{ terms},$$

observe that the last term must be ar^{n-1}, from which it is easily deducible that

$$S = a\,\frac{1 - r^n}{1 - r}.$$

If r is a fraction and n infinite, S assumes the simple form $S = \frac{a}{1 - r}$. Hence, $1 + \frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \ . \ . \ .$ to infinity $= \frac{1}{1 - \frac{1}{2}} = 2$; which is equivalent to saying that the value of the series can be made to differ from 2 by less than any assignable quantity, by simply continuing the series far enough. *Geometrical mean* of any two quantities is the square root of their product, and is evidently the middle term of a G. P. of three terms, the first and last terms of which are the given quantities.

Geom'etry (Gr. *geometria*, 'earth-measurement'), as defined by Sir W. R. Hamilton of Dublin, is the science of pure space, while algebra, which takes no direct cognisance of space, is in contradistinction the science of pure time. Kinematics (q. v.) or the *G. of motion*, combines these two fundamental notions; and, by the introduction of the unit of mass, merges into dynamics. The early origin of G. is wrapped in obscurity; and the ancient tradition that the Egyptians were led by necessity to the invention of the science in order to furnish them with a means of recovering their old landmarks obliterated yearly by the Nile inundations, has no foundation in fact, though backed by the authority of Herodotus. The Greeks undoubtedly obtained much of their knowledge from Egypt; but the Egyptians, in this as in other sciences, probably borrowed largely from the Hindus. The Hindu records are very uncertain as regards date; but Bhascari in the 12th c. A.D. gives a much nearer approximation (3·1416) to the ratio between the circumference and diameter of a circle than was known in Europe at that time. The Hindus also possessed the method of calculating the area of a triangle when the sides are given, and this would of itself necessitate a considerable amount of mathematical knowledge. The Chinese do not seem to have made much progress in the investigation of the properties of space, being barely acquainted with the property of the right-angled triangle; so that it is to India that we must look for the source of G. as well as of the decimal arithmetic and algebra. Thales (600 B.C.) commonly gets the credit of having tran ported G. from Egypt and founded the first Greek school; but Pythagoras (540 B.C.), according to Proclus, was the first to give it in the form of a science. After him come Anaxagoras, who wrote on the quadrature of the circle, Hippocrates, who invented the quadrature of the lunules, Theodorus of Cyrene, and Plato (400 B.C.), who powerfully influenced the progress of the science, and gave a simple and elegant solution of the duplication of the cube. Contemporary with Plato were Leodamas of Thasos, Archytas of Tarentum, and Theætetus of Athens; and a few years later appeared Leo, Eudoxus, Theudius of Athens, Hermotimus, who wrote on *Loci*, Philippus, and Euclid (q. v.). G. had now been extended beyond the straight line and circle, and many of the properties of cones, cylinders, spheres, and conic sections, and even higher curves, were known. Archytas, indeed, is said to have imagined and applied a curve of double curvature. Euclid's great merit lies in his having collected and arranged consecutively all the more important theorems and problems of pure G., although the best evidences of his high mathematical originality are found in the little-known book upon the classification of incommensurable quantities (Book x. of the *Elements*). Several of his works are lost, notably that on *Porisms* (q. v.). After Euclid appeared Archimedes (240 B.C.), who applied mathematics to hydrostatics and other branches of physical science; Apollonius, famous as the discoverer of the subcontrary sections of the cone, and Eratosthenes; and about a century later flourished Nicomedes, the inventor of the conchoid, Hipparchus, who seems to have made some progress in spherical trigonometry, and Hypsicles. After the Christian era, the Alexandrine school continued to prosper under Menelaus (80 A.D.), Ptolemy (125), Pappus (390), and Proclus (440). Diophantus, the introducer of methods more algebraic in character, probably lived about a century later than the last named. The first Latin edition of Euclid's *Elements* was that of Adelard, about 1150 A.D.; but two or three centuries elapsed before G. began to be studied to any extent in Europe. Vieta (1540–1603), by introducing algebraic symbols, prepared the way for Descartes (see GEOMETRY, ANALYTICAL), and for the subsequent development by Newton, Leibnitz, and the Bernoullis of the ancient method of Exhaustions, and Cavalieri's Method of Indivisibles, into the powerful *Calculus*, handled so effectively in physical investigations by Lagrange and Laplace. The rapid growth of this new *Analysis* was accompanied with an evident retrogression in the study of pure G., a result to be deplored, since, in any investigation by the former method, the meaning of the symbols is generally completely lost sight of, and little scope is offered for the cultivation of true mathematical originality. Men like Desargues, Halley, and Maclaurin, however, show in their writings a decided predilection for G. proper; and from these, through the labours of Carnot, Monge, Poncelet, Chasles, and Hamilton, has sprung the ever-growing, and growingly-important modern G. Monge's *Descriptive G.* established the whole theory of *projections*, so important in perspective, in the planning of roads and canals, in naval constructions, in mining, and in fortification, on a firm basis; and Carnot's *Theory of Transversals*, dimly foreshadowed in the works of Pappus, developed, in the hands of Poncelet, into the beautiful and prolific theory of reciprocal Polars (q. v.). Sir W. R. Hamilton's *Quaternions*, the most potent mathematical method at present known, is a still higher stage in the progress of G., for, though it is symbolic in the extreme, the geometrical meaning of the symbols can never for an instant be lost sight of, so that mathematical science is further than ever from sinking into a mere succession of symbolic operations which in themselves mean nothing.

Geometry, Analytical or **Algebraic**, is a branch of pure mathematics, first formed into a systematic method by Descartes. It is more than a mere expression of geometrical relations by algebraic symbols; its great peculiarity rather lies in regarding + and − as no longer simply the symbols of multiplication and division, but as expressing *direction* according to certain conventional rules. Thus if we speak of north as positive, then south will be negative; or if east be positive, west will be negative, and so on. Now a point in space is fixed if we know its Co-ordinates (q. v.) with respect to three given non-coplanar axes meeting at a point; and if this point lie on a certain continuous curve or surface, a relation will hold for its co-ordinates which is true for the co-ordinates of every point on the same curve or surface. The mathematical expression of this relation may be put in the form of an equation, which is known as the equation of the curve in question. The cultivation of this branch of mathematics is of great importance, especially when viewed in connection with dynamics. The best English works on the subject are Salmon's

Conic Sections, Higher Plane Curves, and *A. G. of Three Dimensions.*

Georg (*Der Bärtige*, 'the bearded'), Duke of Sachsen, was born August 27, 1471, and became Duke of Sachsen in 1500. He at first favoured the Reformation, but afterwards became, along with the Duke of Bavaria, its chief opponent in Germany, and forbade Luther's translation of the Bible to be circulated in his dominions. The loss during his latter years of his wife and eight children, and the knowledge that he would be succeeded by his Protestant brother Henrich of Freiberg, cast him into deep melancholy. He led an ascetic life, and let his beard grow to his waist—whence his surname of *Der Bärtige*—for some time before his death, April 17, 1539.

Georg I. (**Christian William Ferdinand Adolf Georg**), King of Greece, second son of Christian IV. of Denmark and younger brother of the Princess of Wales, was born 24th December 1845. He was educated at Copenhagen, entered the navy, and was chosen King of Greece in 1863. G. married the Princess Olga, daughter of the Grand Duke Constantine and niece of the Czar of Russia, in 1867. See GREECE.

George, a district of the W. Province, Cape Colony, is bounded N. by the Zwarte Berge, S. by the G., W. by the district of Zwellendam, E. by Uitenhage. Area, 4032 sq. miles; pop. 20,000. It is well wooded, is watered chiefly by the Gauritz, and has a good wheat-growing soil of loam and clay mixed with gravel and decomposed granite. Georgetown is the capital, and Mossel Bay indents the coast-line.

George (Lake), or **Horicon**, a beautiful lake in New York State, 36 miles long, from 1 to 3 broad, and in parts 400 feet deep. It is studded by about 300 islands, and has an outlet to Lake Champlain.

George, St., a saint in the Latin and Greek Churches, and the national saint of England. One legend makes him a soldier martyred under Diocletian, but according to Gibbon the St. G. of the Catholics is identical with the Arian persecutor George of Cappadocia. This man, who was born about the beginning of the 4th c. at Epiphania, Cilicia, after acquiring wealth by the most flagrant dishonesty, was chosen by the Arians to succeed Athanasius as Archbishop of Alexandria in 356, and ruled there as a cruel, insolent tyrant, persecuting alike Catholics and pagans, until on Julian's accession he was cast into prison, and shortly afterwards was killed by the people, who flung his body into the sea (361). He was viewed as a saint by the Arians, and, says Gibbon, their seeming conversion introduced his worship into the Catholic Church. 'The odious stranger assumed the mask of a martyr, a saint, and a Christian hero; and the infamous George of Cappadocia has been transformed into the renowned St. G. of England, the patron of arms, of chivalry, and of the Garter.' On the other hand, it is contended that the Catholics would never have admitted their bitter persecutor into their hierarchy of saints. St. G., however, though revered in Palestine and Armenia in the 6th c., was not generally known in Europe until the crusades, which first made him famous in England. In 1330 Edward III. made St. G. patron of the Order of the Garter. See Gibbon, ch. xviii., and Heylin's *History of St. G.* (Lond. 2d ed. 1633).

George, St., one of the Bermudas (q. v.).

George, St., Banner of, a white banner with a red cross. In the 14th c. all English soldiers in the royal service wore the red cross of St. George, the patron saint of England, over their armour, and the St. George banner was the national flag until transformed into the Union Jack (q. v.) by being combined with the crosses of St. Andrew and St. Patrick.

George, The, the badge of the Order of the Garter. It represents St. George mounted and piercing the dragon.

George Lewis, known as **George I.**, King of Great Britain and Ireland, was the son of Ernst August, Elector of Hanover and Duke of Brunswick-Lüneburg, and Sophia, grand-daughter of James I. He was born May 28, 1660. On the death of Queen Anne (1714) he became, by the Revolution Settlement, which secured the Protestant succession, King of Great Britain; and although he allowed six weeks to elapse before he came from Hanover to take his throne, and although he was seen by his subjects when he landed at Greenwich to be a little awkward man of fifty-four, who could not speak a word of English, he was heartily welcomed for the cause he represented; and Oxford and Bolingbroke, if they ever contemplated enthroning the Pretender, made no demonstration in his favour. Personally the 'foreign tyrant,' the 'wee, wee, German lairdie,' as G. was dubbed, was never liked, and did not deserve to be. He was honest, and Mr. Carlyle admires him for possessing the gift of silence, probably because he had nothing to say; but his 'temper was that of a gentleman usher,' his manners and morals were coarse and his tastes low; and a French critic has lately not inaccurately summed up his private history by saying that he 'kept his wife in prison thirty-two years, and got drunk every night with his two plain mistresses.' His wife was Sophia Dorothea of Zelle, by whom he had two children, George, who succeeded him, and Sophia, the mother of Friedrich the Great. Believing her to have been unfaithful with Count Philipp von Koningsmark, he shut her up in the castle of Ahlden, where she died, after an incarceration of thirty-two years, at the age of sixty, and only a few months before her husband. But whether from imbecility or not, G. understood the duties of a constitutional sovereign, and threw himself into the hands of the Whig party, which then fortunately had for its leader Sir Robert Walpole, the first of that brilliant series of peace and finance ministers who have made this country a 'nation of shopkeepers.' The chief events of G.'s reign are the Jacobite rising of 1715, which ended in failure; the mad South Sea scheme (1720); a war with Spain, chiefly noted for an unsuccessful attempt on the part of that country to recover Gibraltar; and the passing of the Septennial Act, which is still in force. G. died in his carriage, of apoplexy, June 11, 1727, when proceeding to the palace of his brother the Bishop of Osnabrück. — **G. II.** was born at Hanover, 30th October 1683, and was in his forty-fifth year when he ascended the British throne. Although he could speak English, he was thoroughly German at heart, and preferred his electorate to his kingdom. He has been described as a 'drill-sergeant who believed himself master of his realm, while he repeated the lessons he had learned from his wife, and which his wife had learned from the minister.' This wife was the handsome and accomplished Carolina Wilhelmina, daughter of the Markgraf of Anspach. By her he had two sons, both of whom died before him, and three daughters. She died in 1737 to the great grief of her husband, although the tone of his morals may be judged from his declaration to her that he would never marry again, but only keep mistresses. G.'s reign is one of the most eventful in British history. It witnessed the fall of Walpole and the rise of Pitt; the last attempt of the Jacobites, which ended in the battle of Culloden (q. v.); wars with Spain and France, chequered by the victory of Dettingen (1743) and the defeat of Fontenoy (1748), and ending in the peace of Aix-la-Chapelle (1748); the capture of French Canada, closing with the victory and death of Wolfe (1759); the foundation of the English empire in India by Clive, who won the great battle of Plassey in 1756; and the victory of Minden (1759), all part of the Seven Years' War; the rise of Methodism, of which the chief promoters were John Wesley and George Whitfield; the adoption (1752) of the Gregorian reform in the calendar; a great development of literature and art, showing itself especially in fiction and caricature; and the doubling—chiefly owing to the Seven Years' War—of the National Debt. G. died suddenly of heart-disease at Kensington, October 25, 1760.—**G. III.**, eldest son of Frederick Louis, Prince of Wales, was born June 4, 1738, and succeeded his grandfather, G. II., on the throne in 1760. On 8th September of next year he married the Princess Charlotte Sophia of Mecklenburg-Strelitz, a lady of exemplary and even pious character, by whom he had fifteen children. G.'s mind was naturally narrow, and he was trained carefully in the matter of morals, wretchedly as regards the development of the intellect. The dullest and most respectable of kings, he did more public mischief than all the other Georges put together; the British public condoned in the 'good old king' and 'Farmer G.' what they would have resented and resisted in another. Although his general education was so defective that he spoke impatiently of Shakespeare as 'such stuff,' his mother had taught him to assert himself as a monarch; and his efforts—honest no doubt—to do this, finding a tool in Lord North, 'the most amiable of men, the worst of ministers,' were the means of bringing about the separation between the country

and her American colonies. G.'s personal life is chiefly notable for his attacks of insanity in 1764, 1788, 1801, 1804, and 1811—the last continuing to the end of his reign; his troubles with his family, particularly with his eldest son, afterwards George IV.; and his Royal Marriage Bill (12 Geo. III. c. 11), forbidding (1772) the members of the royal family to marry without the consent of the monarch if under twenty-five years of age, and the consent of Parliament if above that age. The reign of G. III. is one of the most eventful in the history of Britain and of mankind. Here we need only make an enumeration of the leading events. The two most important were the American War of Independence and the French Revolution. The former, caused by the attempt of the government of the day to tax the colonists against their will, began in the battle of Lexington (19th April 1775), and ended in the capitulation (1781) of Earl Cornwallis at York Town to French and American troops, followed by the recognition (1783) of the United States. During this period Spain, France, and Holland joined in war against Britain; and the remarkable point in connection with the war is the ability which Britain showed to contend against the world in arms. During this war British gallantry and seamanship were evidenced in Rodney's great victory (1782) over the Comte de Grasse, and Elliot's defence of Gibraltar against the forces of France and Spain for three years and seven months. Elsewhere we record the wars occasioned by or subsequent to the French Revolution, which were marked by the great naval victories of Howe, Duncan, Jervis, and Nelson, and the subsidising of Continental coalition upon coalition against Napoleon Bonaparte by Pitt, and which ended in the battle of Waterloo, June 18, 1815. Among the other events of the reign are the consummation of the Union with Ireland, 1st January 1801, which, however, did not put a stop to Irish troubles and grievances; the Wilkes and Lord George Gordon Riots; the consolidation of our Indian empire under Warren Hastings and Earl Cornwallis; and a second war with the United States, ending in 1815; the reform of prison management promoted by Howard; and the passing in 1807—mainly through the exertions of Clarkson and Wilberforce—of an Act abolishing the slave trade. In this reign the chief statesmen were the elder and the younger Pitt, Fox, Burke, Shelburne, Liverpool, and Castlereagh. The 'strike system' commenced with the outbreaks of the 'Luddites;' scientific invention began under the auspices of the James Watt steam-engine to revolutionise the world; trade and commerce flourished in spite of the war; vaccination and gas became necessities; Captain Cook and others found new fields for emigration in Australia and New Zealand; the punishment of death for minor offences was removed from the statute book; and literature and thought of all kinds, especially poetical, found fresh vents and vigorous expression, as the names of Walpole, Johnson, Burke, Sheridan, Burns, Cowper, Crabbe, Wordsworth, Coleridge, Scott, Byron, Shelley, and Keats are sufficient to show. G. died at Windsor Castle, 29th January 1820, leaving six sons and five daughters.—**G. IV.** was born 12th August 1762, and succeeded to the throne on the death of his father. He was a man of considerable amiability and of fascinating manners, which in the eyes of many covered the multitude of his sins, but his private life was almost as great a scandal to the British monarchy as that of Charles II. It has indeed been said that he was 'a sort of coachman, gamester, scandalous roysterer, unprincipled betting-man, whose proceedings all but got him expelled from the Jockey Club.' On August 8, 1794, when Prince of Wales and deeply in debt, he married his cousin Caroline Amelia Elizabeth, Princess of Brunswick-Wolfenbüttel. There was little affection between G. and his wife, who seems to have been a person of somewhat coarse manners, and altogether indiscreet in her conduct. The only issue of the marriage was the Princess Charlotte Augusta (born 7th January 1796), who married Prince Leopold of Belgium, and died 6th November 1817. One of the most famous events of the reign of G. was his attempt to procure a divorce from Queen Caroline on the ground of immorality. It broke down, but Caroline, who was very popular with the nation, was much chagrined by being prevented from being present at G.'s coronation in Westminster Abbey, and died August 7, 1821. The other leading events of the reign were the break-up of the alliance of the European powers, followed by the formation of a league between Great Britain, France, and Russia, on behalf of Greece, which ended in the battle of Navarino (October 20, 1827), the passing of the Catholic Emancipation Act (13th April 1829), a Burmese war (1824–26), a financial panic (1825), the placing (1829) of the metropolitan police force upon a proper footing, and the death of Canning followed by the rise of Peel. G., who had led a secluded life for some time, died at Windsor Castle, January 26, 1830.

For details of the private and official history of the four Georges, see, among other works, Coxe's *Life of Sir Robert Walpole*; Horace Walpole's *Memoirs of the Reign of George II.*, *Letters to Sir Horace Mann*, and *Memoirs of Early Reign of George III.*; Hervey's *Memoirs from the Accession of George II. to the Death of Queen Caroline*; Stanhope's *History of England from the Peace of Utrecht*; Bancroft's *History of the United States*; Massey's *History of England from the Accession of George II.*; May's *Constitutional History*; Napier's *History of the Peninsular War*; F. Thackeray's *Life of Chatham*; W. M. Thackeray's *Lectures on the Four Georges*; Southey's and Tyerman's biographies of Wesley; *The Rockingham Memoirs*; *The Greville Papers*; Earl Russell's *Life and Correspondence of C. J. Fox*; *The Correspondence of George III. with Lord North*; *Greville's Diary*, edited by W. Reeve; Fitzmaurice's *Life of Lord Shelburne* (3 vols. 1876); and Leslie Stephen's *History of English Thought in the Eighteenth Century* (1876).

George's Channel, St., lies between Wales and the coast of Ireland from Dublin to Wexford, and communicates in the S. with the Atlantic, in the N. with the Irish Sea. It varies in width from 75 to 60 miles, and is about 100 miles long.

George'town, a town of Maryland, on the Potomac, 2 miles W.N.W. of Washington, and a terminus of the Chesapeake and Ohio Canal. It stands on a series of heights, and has many fine buildings, a college under Catholic management, and several schools. Its trade has somewhat declined, but its flour manufactures are very large, and there are paper, leather, iron works, &c. Pop. (1870) 11,384.

Georgetown, the capital of British Guiana, at the mouth of the Demerara. It is the see of an Anglican bishop, is regularly built but unhealthy, and the streets, which are traversed by many canals, are shaded by rows of cabbage-palms, cocoa-nut, and orange trees. The chief buildings are a handsome town-hall with beautiful marble pavements, an episcopal cathedral, a colonial hospital, a mariners' hospital, barracks, and a theatre. G. exports mainly sugar and coffee. A line of rail is being carried hence to New Amsterdam, a distance eastward of 60 miles. Pop. 26,000, of whom 6000 are whites.

Geor'gia (Pers. *Gurjestan*, Russ. *Grusia*, native *Iberia*), a district in the Russian lieutenancy of the Caucasus (q. v.), formerly an independent state, so named either from St. George or from the many Georges who ruled over the country. It now includes the governments of Tiflis and Kutais, and has an area of 38,250 sq. miles, and a pop. of 1,100,000. The country, which is watered by the Kur and its many tributaries, is very fertile, and has a mild, healthy climate. The Georgians, who are of Iranic race, and mostly belong to the Greek Christian Church, are famed for their strength and beauty. Of the four branches into which they are divided, the Karthuli speak the purest Georgian. The history of G. emerges from fable in the time of Alexander the Great, who brought the land under subjection. Freed from the Macedonian yoke by Pharnawas on the death of Alexander in 324 B.C., G. remained, with interruptions, for upwards of 2000 years under its own kings or *mephé*. In the 4th c. it received Christianity, and subsequently suffered much from the raids of the Sassanides and the Arabs, till eventually it was made a province of the Califate in the 8th c. After a brief gleam of liberty, G. again passed into the power of Mohammedan rulers of Persia in the 9th c. Towards the end of the 10th c. it once more struggled into independence under Bagrat III., to enter on a period of wise internal rule and of flourishing trade. The reign of Bagrat VI. (1360–96) was disturbed by the irruption of Timur, who forced the faith of Mohammed on the inhabitants. Georg VII. (1396–1407) restored Christianity. His successor, Alexander I., divided the kingdom between his three sons. Subdivision once begun was carried on till G. had twenty-six princes. The eastern states Karthuli and Kachetien early came under the dominion of the Persian Shahs, and the Georgian princes sought by aid of the Czar (since 1579) to obtain freedom. In 1783 Heraclius II. formally

declared himself a Russian vassal, and George XI. resigned in favour of the Emperor Paul in 1799. The western states Imerethi, Mingrelia, and Guria suffered greatly from civil conflict, were overrun by Caucasian mountain tribes, and finally were brought under allegiance to the Turks in 1536. One by one the states have been transferred to Russia (1803–38). See Brosset, *Histoire Ancienne et Moderne de la Georgie* (5 vols. St. Petersb. 1849–57); Bodenstedt, *Die Völker des Kaukasus* (2 vols. Frankf. 1855); Haxthausen, *Transkaukasia* (Leips. 1856). The Georgian speech, rude in sound, but strong and regular, agglutinative in character, is descended from old Colchian, Albanian, and Iberian, and together with Suanen and Lasen forms a special branch of language, which has an alphabet of its own, and which assumed a written form in the 10th c. A literature sprang up under the influence of the Byzantine empire, and includes chiefly translations of the Bible, of the fathers, of Plato, Aristotle, &c. In the 12th c. appeared a few heroic poems; in the 17th c. many songs and chronicles attest the influence of Armenia and Persia. Under the Russians G. has made great advances in education and culture. The national archives were removed to St. Petersburg in 1807. See Brosset, *Éléments de la Langue Géorgienne* (Par. 1837), and *Rapport sur un Voyage Archéologique dans la Georgie* (St Petersb. 1850–51).

Georgia, one of the original states of the American Union, is bounded N. by N. Carolina and Tennessee, W. by Alabama, S. by Florida, E. by the Atlantic and S. Carolina. Area, 58,000 sq. miles; pop. (1871) 1,184,109, of whom 545,142 are coloured, and 40 Indians. The surface for 20 miles from the coast is low and swampy and is partly under rice crops and partly covered by saw-palmettoes, cypress, cedar, live oak, magnolias, gum-trees, canes, and other semitropical trees. Two terraces, of 20 and 100 miles' breadth respectively, extend to the centre of G., where a height is attained of 575 feet. The N.W. portion of the state is intersected from S.W. to N.E. by the parallel ranges of the Appalachians [illegible] which rise to an extreme height of 4000 feet, [illegible] which extends a wild romantic [illegible] valley, and foaming cascade. The [illegible] flow S.W. between the two hill ranges, the [illegible] N.E., and the Chattahoochee [illegible] while other rivers flowing S. are the [illegible], Flint, [illegible], &c. The coast-line is indented by many [illegible] and fringed with small islands (the large [illegible] which yield fine cotton. The staple of G. are Indian corn (in 1873 23,500,000 bushels), and cotton, the [illegible] which amounted in 1873 to 614,030 bales. Other crops [illegible] (in 1870, 22,277,380 lbs.), wheat [illegible] rye, sweet potatoes, [illegible], ground-nuts, sugar-cane, &c. In the centre of G. [illegible] forests of black walnut, chestnut, tulip-tree, hickory, [illegible] sycamore, beech, maple, &c.; while in the S.E. flourish [illegible] orange, lemon, banana, olive, and vine. A vast deposit of fine bituminous coal enters in the N.E., while the [illegible] is rich in iron ore, gold, copper, silver, lead, zinc, [illegible], marble, and petroleum, chalybeate, and sulphur springs. Gold-mining was discontinued in 1861, but is being renewed by means of the hydraulic process on a large scale. The climate in the lower valleys and levels is unhealthy. Among the wild animals are the black bear, panther, wild cat, opossum, and racoon; the tick, sandfly, and mosquito are the chief insect pests. Atlanta (q. v.) is the capital, and other cities are Augusta, Macon, and Columbus. G. sends nine representatives to Congress. It derived its name from George II., and received its first colony in 1733. The Creeks and Cherokees were frequently troublesome, but the former finally ceded their territory in 1802, and the latter removed to the Indian territory W. of Arkansas in 1838. As a slave-holding state G. suffered greatly in the late war, Sherman's devastating 'march to the sea' ending with the capture of Savannah.

Georgia, Gulf of, is, strictly speaking, a channel and a northerly extension of Puget's Sound, separating Vancouver's Island from the mainland of British Columbia. It terminates in the N. in Queen Charlotte's Sound, in the S. in the Strait of Fuca (q. v.), receives the Fraser river, and is 20 miles broad on an average, and 100 miles long.

Geoteu'this, a genus of fossil Dibranchiate or two-gilled Cuttlefishes (q. v.), belonging to the family *Teuthidæ*, but referred by some palæontologists to that of the Belemnites (q. v.). Species occur in the Oolitic rocks.

Gephyr'ea, the name given to a class of lower *Annulosa* (q. v.), represented by such forms as the *Sipunculi* or 'spoon-worms,' found in the sand of the English coasts. They are nearly allied to the *Annelida* (q. v.) or true worms, but differ from them in some important particulars. Thus, while the body is usually annulated or segmented, it may be perfectly smooth. In the majority of cases it wants appendages, and the ventral nervous cord is not provided with ganglia or nervous enlargements. The sexes are distinct and the young appear to undergo a metamorphosis in the course of their development. *Sipunculus Bernhardus*, found burrowing in the sand of the coasts, is a familiar species. The anterior extremity is provided with a retractile trunk or proboscis, and the digestive system is convoluted. *Syrinx* is a second genus of G. and *Echiurus*, which occurs in the N. Sea, has [illegible] bristles.

Gepidæ, or **Gepi'di**, one of the chief Gothic tribes, are first mentioned about 280 A.D. as dwelling near the mouth of the Vistula. They gradually moved S. into Pannonia, and settled between the E. and W. Goths. Their power was destroyed by Alboin (q. v.) the Longobard in 566.

Gera, a German town in Reuss-Schleiz, the principality of the younger branch of the Reuss family. It stands on the White Elster, [illegible] miles S.S.W. of Leipsic, and is connected by railway with the Thuringian line of Central Germany. G. is a thriving place, has broad streets and several fine buildings, a castle, town-hall, and gymnasium. The chief manufacture is woollen stuffs, but cotton, harmoniums and pianos, soap, and leather are also made. There is a large brewery, and much gardening is carried on. Pop. (1871) 17,957.

Gera'ce, an old town of S. Italy, in the province of Reggio di Calabre, on a hill 4 miles from the sea, and 3 miles N.E. of Reggio. It is a bishop's see, and has a trade in silk and wine. Near it are lead, zinc, and iron mines. Pop. 7200. On the destruction of the ancient Locri (q. v.) by the Saracens in the 12th c., its inhabitants built a new town *Santa Ciriace*—corrupted into G.—about 4 miles from Locri, the ruins of which lie in the plain between G. and the sea. G. was greatly injured by an earthquake in 1783.

Gerania'ceæ, a natural order of Thalamifloral Dicotyledonous plants, including about seven genera and 700 species. They are found in various parts of the world. The species of *Pelargonium* (q. v.), which have very showy flowers, and of which numerous hybrids are now cultivated in greenhouses, abound at the Cape of Good Hope. The genus *Pelargonium* is distinguished from that of *Geranium* (q. v.) by having the flowers irregular and spurred. The plants of the order are aromatic and astringent.

Gera'nium, the genus of plants from which the Dicotyledonous natural order *Geraniaceæ* (q. v.) takes its name. There are thirteen species found growing wild in Britain, which are called crane-bills, from the long beak of their fruit. The tuberous roots of *G. parviflorum* of Tasmania and those of *G. tuberosum* of the S. of Europe are used as food. The rhizome of *G. maculatum* of N. America is called Alum Root (q. v.).

Gér'ard, **Étienne Maurice, Comte**, a distinguished French soldier, was born at Damvilliers in Lorraine, April 4, 1773. He figures first in Dumouriez' celebrated campaign of 1792-93, then attached himself especially to Bernadotte, to whom in 1805 he became aide-de-camp, while he contributed greatly to some of the greatest victories of the Emperor—such as Austerlitz, Jena, and Wagram. Made a count of the empire, G., who had fought both in the Peninsular and in the Russian war, yet received various appointments and honours after the Bourbon restoration. After his former master's return from Elba, G. joined him, and gave Grouchy the bold advice (which was not taken) on the day of Waterloo to march to the assistance of the Emperor. In 1822 he returned to public life as a member of the Chamber of Deputies, put down revolutionary movements in Paris in 1830, became a marshal of France in 1831, took Antwerp, December 23, 1832, was made the same year a peer of France, in 1835 was appointed Grand Chancellor of the Legion of Honour, and in 1838 general of the National Guards of the Seine. Under the Third Empire G. became (1853) a senator. His death took place 17th April 1855.

Gérard, François Pascal Simon, Baron, a distinguished painter, was born of a French father and Italian mother at Rome, 11th March 1770. He studied painting under David in Paris, became known through his 'Blind Belisarius' in 1795, and rose to be the first of contemporary French portrait-painters. He was made a baron by Louis XVIII. for his 'Entry of Henri IV. into Paris,' his masterpiece, and died at Paris, January 11, 1837. Among his works, which comprise many historical pictures as well as portraits, are 'Cupid and Psyche,' 'Battle of Austerlitz,' 'Coronation of Charles X.,' 'Thetis bearing the Armour of Achilles,' 'Ossian's Dream,' 'Daphne and Chloe,' 'Philip V.,' 'Homer,' &c. In his early paintings G. imitated the antique statuesque style of David, but several of his later works are spirited in design, glowing, varied, and harmonious in colour, and scrupulously accurate in costume. His portraits represent a number of the celebrities of his time.

Ger'asa, one of the ten cities of Decapolis (q. v.), and one of the finest cities of Palestine under the Antonines (130–180 A.D.), lay among the mountains of Gilead, 20 miles E. of Jordan. Its ruins are the most magnificent in the Trans-Jordanic country, surpassing even those of Palmyra. See Porter's *Handbook for Travellers in Syria and Palestine* (new ed. Lond 1868); Buckingham's *Travels in Palestine*, &c. (Lond. 1821).

Ger'ba, or **Jer'ba,** an island of Tunis, in the Gulf of Cabes, 130 miles N.W. of Tripoli, is 12 miles broad and 20 long. It is noted for its manufactures of coloured shawls, fine silks and woollens, blankets, &c.

Ger'hard, Johann, born at Quedlinburg, 17th October 1582, died Professor of Theology at Jena, 17th August 1637. He is generally ranked next to Luther and Chemnitz amongst the great Lutheran divines. His *Loci Theologici* are the foundation of the more developed systematic form of orthodox Lutheranism, and were first published in 1610 in 10 vols. An enlarged edition (22 vols.) appeared 1622–89, of which a reprint was begun by Ed. Preuss in 1863. The *Confessio Catholica* is polemic, while the *Meditationes Sacræ* are an outcome of the warmest personal piety.

Ger'hardt, Charles Frédéric, a French chemist, was born at Strasburg, August 21, 1816. After studying for two years at Karlsruhe, he proceeded to Leipsic in 1833, and under Erdmann developed his taste for chemistry. In 1835 he was working in Liebig's laboratory at Giessen, and in 1838 at Paris, where he was soon engaged with Cahours experimenting on the essential oils. From 1844 to 1848 he was Professor of the Sciences at Montpellier, a position which he resigned in order to establish a chemical laboratory in Paris. Here he worked upon *homologous series*, the *theory of types*, *anhydrous acids*, &c., till 1855, when he was appointed Professor of Chemistry at the École Supérieure of Strasburg. He was shortly after elected corresponding member of the Académie des Sciences. G. died August 19, 1856. His theories and discoveries, which have greatly influenced modern chemistry, are sketched and developed in his two principal works, *Précis de Chimie Organique* (1844–45), and *Traité de Chimie Organique* (4 vols. 1853–56).

Gerhardt, Paul, one of the foremost of German hymn-writers, was born 12th March 1607, at Gräfenhainichen, in Saxony. After he came to Berlin as pastor in 1657, he was known as the leader of the extreme Lutheran party in the embittered theological strife of that period. As such he was deposed by the Government in 1666, though soon reponed. He died an archdeacon at Lübben, 7th June 1676. G.'s hymns (*Geistl. Andachten*), first published in 1666, are very popular; they have been frequently reprinted, the latest edition being that of Bachmann in 1866. Biographies of G. have been written by Langbecker (Berl. 1841) and Bachmann (Berl. 1863).

Ger'izim and E'bal, according to the almost unanimous opinion of travellers, are the mountains which form the sides of the valley in which lies Nablus, the ancient Shechem—E. on the N. and G. on the S. In this valley the Israelites assembled soon after their arrival in Canaan, in obedience to the instructions of Moses. The law, with the blessings and cursings attached to it, was read by Joshua surrounded by the Levites, and stationed apparently in the middle valley. Six of the tribes on the slopes of E. gave back the response 'Amen' when the curses were read, and the other six on G., when the blessings were read (Deut. xi. 29, xxvii.; Josh. viii. 30–35). This is the only mention of E. in the Old Testament history, and the only other mention of G. is in connection with the parable of Jotham (Judges ix. 7). It was on E. that Joshua built the altar to Jehovah (viii. 30); according to the Samaritan Pentateuch it was on G. There are two Samaritan traditions regarding G.—the one that it was the spot where Melchizedek met Abram (Gen. xiv. 18–24), the other, which Stanley thinks much more likely to be true, that it was the place where Abraham was to offer up Isaac (Gen. xxii.). Sanballat, the Persian satrap, built a temple on G., about B.C. 420, for his son-in-law, a son of the high-priest's, who had been excommunicated for the foreign alliance (Neh. xiii. 28; Jos. *Ant.* xi. 8, 2–4). This temple was destroyed by John Hyrcanus about 129 B.C., and does not appear to have been rebuilt, but G. continued to be a holy place to the Samaritans for centuries. For their attacks on the Christians they were driven from G. about 487 A.D., and a Christian church built on it. The ruins which now crown its summit are probably those of the fortifications built by Justinian for the defence of the church. The Samaritans annually celebrate the Passover on G. to this day. See Porter's *Handbook for Travellers in Syria and Palestine* (new ed. Lond. 1868); Robinson's *Bib. Researches* (3d ed. Lond. 1867); Stanley's *Sinai and Palestine* (new ed. 1871).

Ger'ki, a walled town of Africa, in the Sudan, near the E. frontier of Sokoto, and on the border of Bornu, 11 miles N.E. of Kano. The inhabitants, who are Fellatas, and are of noted predatory habits, number some 15,000.

Ger'lache, Étienne Constantine, Baron de, a Belgian politician, was born at Biourge, in Luxemburg, December 26, 1785. He entered the second chamber of the États-Généraux as deputy from Liége in 1824; became President of Congress in 1831, receiving as such the oath of allegiance to King Leopold; and was nominated first president of the Cour de Cassation in October 1833, after which he retired from active legislation, still, however, occupying a prominent position as one of the chief leaders of the Catholic party. He has written several historical works, such as *La Révolution de Liége sous Louis de Bourbon* (1831); *L'Histoire du Royaume des Pays-Bas* (2d ed. 3 vols. 1842); *L'Histoire de Liége* (1843); *Essais sur les Grandes Époques de notre Histoire Nationale* (1852); and *Observations Critiques sur l'Histoire de Jules César par Napoléon III.* (1865).

Ger'man (Lat. *germanus*, 'derived from the same *germen*,' 'germ') is a term applied to those born or descended from the same father or mother, and thus related in full blood.

German, Cousins, or **First Cousins,** are all those not being brothers and sisters who have had the same grandfather.

German (San), a town in the S.W. of Puerto Rico, in the W. Indies, on a small river, 10 miles from its mouth. It has some trade in cotton, coffee, cattle, &c. Pop. 9125.

German Barm. See YEAST.

Ger'man Cath'olics (*Deutschkatholiken*) is the usual name for a sect formed about 1844 by secession from the Catholic Church in Germany. The immediate occasion of the secession was the solemn exhibition of the Holy Coat at Treves in 1844, accompanied by an episcopal promise of remission of sins as reward for a pilgrimage to this sacred relic. Johann Ronge, a Silesian priest, became spokesman of the widespread feeling of contempt for this mummery; and he soon found a helpmeet in Czerski, a priest who had already seceded from the Catholic Church. Their united labours produced a powerful effect in many parts of Germany, and separatist congregations soon began to form themselves. The earliest, organised at Schneidemühl in Posen, under the pastorate of Czerski, published its confession of faith in 1844—a formula which departs but little either from the doctrine or ritual of the Catholic Church, while rejecting the use of Latin in the service. The confession drawn up by Ronge for his congregation at Breslau went much further in its dissent from Rome, and the spirit of Ronge's manifesto was that which triumphed in the first council of the G. C., held at Leipsic in 1845. Scripture interpreted by the unfettered reason was declared the only rule of faith; belief in God as Creator and in Christ as Saviour was retained; the celibacy of the clergy was abolished; and congregations were declared to have the right to elect their pastors and officers. By the end of 1845

there were as many as 298 congregations of G. C. A few Protestants joined them, and leading men of all parties regarded the movement as full of significance for the future of German ecclesiastical life. The highly repressive measures of almost all the German Governments was less a check to the development of the body than the diversity of aim and of belief that speedily showed itself between Ronge and Czerski and the parties headed by them. Ronge moved steadily in the direction of free-thinking, and he and his adherents began to show their zeal less in matters religious and ecclesiastical than in the field of politics. The democratic and socialistic views of Ronge's party shocked all who retained anything of conservatism in religion or in politics, and not merely led to open secession and the disruption of numerous congregations, but drew on the whole body in a still higher degree the suspicion and hostility of the German Governments. The reactionary policy that predominated after 1848 told heavily on the German Catholic associations, even when they were not, as was frequently the case, formally prohibited from assembling. Ronge retired to London; the whole organisation began to fall to pieces. Such German Catholic congregations as still remained saw their way in 1850 to join the association of the 'Free Churches' (*Freie Gemeinden*). These Churches were the result of the continued struggle between the rationalistic and the orthodox sections within the Protestant Church. The desire for entire theological freedom led numerous congregations to secede from the national churches, the first being formed in 1841. These separatists have been always much more fully agreed in what they are to disbelieve than in any positive articles of faith, and are generally regarded as wholly without the pale of Christianity. About the time of their union with the G. C., the free-thinking congregations numbered 104. The united body has not thriven, the council held in 1865 at Gotha was attended by only fifty-six members.

German'der, a common name for the species of *Teucrium*, a genus named from Teucer, Prince of Troy, who is said to have first used G. medicinally. *T. chamædrys* is the common G. or wall G., which has been introduced into Britain, and was formerly used in cases of gout and rheumatism. *T. scorodonia*, the wood G., is frequent in Britain. It is extremely bitter, and has been used in place of hops. *T. scordium* is the water G., and *T. marum* is called cat thyme, which causes sneezing. The plants belong to the natural order *Labiatæ* (q. v.).

Germa'nia, called *G. Magna*, *Transrhenana*, or *Barbara* in contradistinction to *G. Prima* and *G. Secunda* (the N. and N.E. of *Gallia Belgica*), was bounded on the N. by the *Mare Germanicum* (German Ocean) and the *Mare Suevicum* (Baltic), on the E. by the Vistula, on the S. by the Danube, and on the W. by the Rhine and the German Ocean. The name G. is supposed to be derived from the Celtic *gaire*, *gairm*, *gairmean* ('a cry'), the habit of the Germans being to utter the war-shout as they rushed to battle. Tacitus divides the Germans into three great groups—the *Ingævones* in the N.W., the *Herminones* in the centre, and the *Istævones* in the E. and S. The Teutones are the first German tribe known to history. They were defeated by the Consul Papirius 113 B.C., and were completely crushed by Marius 102–101 B.C. From 72 to 55 B.C. some German tribes under Ariovistus, chief of the Marcomanni, overran the greater part of Eastern Gaul. In the latter year this prince was defeated by Cæsar in the territory of the Sequani, and forced to recross the Rhine. In 55 and 54 B.C. Cæsar twice entered German territory, but was compelled to retire. In 12 B.C., Drusus, stepson of Augustus, led an expedition against the Germans, advanced as far as the *Albis* (Elbe), subdued the Frisii, Batavi, and Chauci, and inflicted a severe blow on the Catti. Being killed by a fall from his horse 9 B.C., he was succeeded in the command by his brother Tiberius, who conquered the tribes between the Rhine and the Weser. In A.D. 9, under Arminius, chief of the Cherusci, they again rose and defeated the Romans in the Teutoburg Forest, and freed themselves from foreign sway. Violent commotions now broke out among the Germans, and the Romans gradually established themselves in the S.W. of G. From A.D. 16–68, the *agri decumates*, or tithe-lands, were formed on the E. of the Upper Rhine, and on the N. of the Upper Danube. In A.D. 70–71 the Batavi revolted. This was followed by a series of struggles which culminated in the sanguinary Marcomannian war, when the Germans invaded Italy and besieged Aquileia (166 A.D.). In 180 A.D. the Emperor Commodus purchased peace and surrendered the forts on the Danube. After this the Roman power in G. rapidly waned; the Germans began to harass their old neighbours, and at last, pouring forth in countless hordes, swept like a hurricane the countries of Gaul, Italy, and Spain, and planted their victorious standards in Britain and Africa. By the end of the 5th c. nearly the whole of Western Europe was subject to German sway.

G. is described as a country of swamps and forests. Its chief rivers are the Rhenus, Danubius, Amisia (*Ems*), Visurgis (*Weser*), Albis (*Elbe*), Viadrus (*Oder*), and Vistula. The people were a branch of the Aryan race. They are described by Cæsar and Tacitus as tall, strong, fair-complexioned, yellow-haired, and animated by an intense love of liberty. Their women were distinguished for their chastity. Their dwellings were rude huts, generally separate, and, though villages were not uncommon, towns were regarded by them with great aversion, and hardly existed except on the banks of the Rhine. The territory was divided for political purposes into districts (*pagi*), each of which had its own magistrate. The people were divided into four classes—nobles, freemen, freedmen, and slaves. The chiefs, and probably the magistrates, were elected from the nobles. Of the religion of the Germans little is known. They worshipped the sun, moon, and stars, Tuisco, the ancestor of their race, and his son Mannus, and a number of greater gods. Their sacred rites were celebrated in groves and forests or on the lone hillsides. They practised divination, cherished a belief in a future state, and peopled air and earth and water with numberless inferior deities, such as elves, nixes, dwarfs, and giants. See Müller, *Geschichte und System der altdeutsch. Religion* (1844); and Kuhn, *Zur ältesten Gesch. der Indogerman. Völker* (Berl. 1850).

German'ic Folk-Laws. After the migrations of the Germanic races had subsided, their old laws were gradually embodied in Latin, generally by private effort. They are chiefly of a penal character, and are distinguished from the Roman law and the capitularies of the Frankish kings as *Leges Barbarorum:*—(1) *Lex Salica* and *Lex Ripuariorum*, the laws respectively of the Salic and Rhenish Franks; (2) *L. Burgundiorum* (before 501), or *L. Gundobaldi*, or *Loi Gombette* (from King Gundobald), a formal code, with traces of the influence of the Roman law; (3) *L. Visigothorum*, recorded by King Enrik at the end of the 5th c., but, after the West Goths were driven back to Spain, so grafted on Roman law as to become a distinct growth, the main stem of the modern law of Spain, and which, incorporated into a law-book (the *Forum Judicum*) about the middle of the 7th c., was in the 13th c. translated into Spanish under the name *Fuero Juzgo*; (4) *L. Longobardorum* (the oldest part, 'Edictum Lotharis,' dating from 643), extended by successive Longobardic, Frankish, and German kings and emperors, and recognised as a system of law for all Italy, the whole being collected (beginning of 12th c.) under the title *Lombarda*, or *Liber Legis Longobardicæ*, and enriched with the glosses of the University of Bologna; (5) *L. Alamannorum* (the modern Swabians), coeval with the Ripuaric or Rhenish; (6) *L. Baiuvariorum* (or Bavarians), recorded between 622 and 638, and very like the preceding; (7) *L. Saxonum*, from the same time; and (8) *L. Angliorum et Werinorum, i.e., Thuringorum*, also from the beginning of the 9th c.

German'icus Cæ'sar, son of Nero Claudius Drusus and Antonia, daughter of M. Antony and niece of Augustus, was born 15 B.C. In A.D. 4 he was adopted by his uncle Tiberius. In A.D. 7 he was quæstor, and in the same year accompanied Tiberius against the Pannonians and Dalmatians. He returned in A.D. 10 to announce the successful issue of the war, and was honoured with triumphal insignia and the rank of prætor. In A.D. 12 he was elected consul. On the death of Augustus, 14 A.D., the legions in Germany and Illyricum, dissatisfied with their pay, the long period of service, and the severity of the military tasks, rose in revolt. G. whose frank and open manners made him the idol of the army hastened from Gaul to establish order in the camp. He was offered the imperial power by the troops, but declared that he would rather die than turn traitor. Having satisfied the demands of the soldiery, he continued the German war in A.D. 15, and in the following year defeated Arminius, whereupon Tiberius jealous of his glory recalled him to Rome. On his return he was received with great enthusiasm, and on the 26th May A.D. 17 he celebrated a

triumph over the conquered tribes, Thusnelda, wife of Arminius, following in the procession of captives. The eastern provinces were now assigned to G., but his influence was thwarted by Cn. Piso, whom Tiberius had appointed governor of Syria. In 18 A.D. G. entered on his second consulship at Nicopolis, after which he visited Egypt. On his return he was seized with a serious illness, and died at Epidaphne, 9th October A.D. 19, in the thirty-fourth year of his age. His ashes were carried to Italy by his heroic wife, Agrippina (q. v.), and deposited in the mausoleum of Augustus. G. was learned, benevolent, and generous. He wrote a verse translation of the *Phænomena* of Aratus; a physical poem, entitled *Diosemeia* or *Prognostica*, compiled from Greek sources; and a number of epigrams, one of which, on a Thracian boy, has been much admired. G.'s remains were first printed at Bologna (fol. 1474). The latest edition is that of A. Breysig (Ber. 1867).

German Ocean. See NORTH SEA.

Germa'no, San, or **Casi'no,** a town in the province of Caserta, S. Italy, 50 miles N.N.W. of Naples. It stands picturesquely on the small river Rapido, is overlooked by an old castle of very great antiquity, and occupies the site of the Volscian *Casinum*, which was made a Roman colony in 312 B.C., and from the ruins of which G. arose in the middle ages. An alliance was formed here by Gregory IX. and Friedrich II. in 1230. Near G. is the famous monastery of Monte Casino (q. v.).

German Paste, the name of a preparation for feeding cage singing-birds, made with peameal (1 lb.), blanched sweet almonds (½ lb.), lard (2 oz.), raw sugar (3 oz.), and hay saffron (7 grains). The addition of an egg is an improvement. Beat these materials into a paste with water, strain, and dry or use.

German Silver, a hard, silvery-white compound of copper, zinc, and nickel in variable proportions, used extensively in the arts. Two kinds for *casting* have the following percentage composition :—First quality, copper 50, zinc 25, nickel 25; second quality, copper 62·5, zinc 25, nickel 12·5. The alloy for *rolling* contains 100 parts—57·1 of copper, 19 of zinc, and 23·9 of nickel. This has entirely superseded copper as the foundation of electro-plated goods. In the rolling mill it is reduced to sheets of the required thicknesses, which are by the process of 'raising,' 'beating up,' 'spinning,' or stamping, formed into forks, spoons, bodies and other parts of table-dishes, vases, &c. Hard solder, composed of 5 parts of G. S. and 4 parts zinc, is used to unite the parts before the article is submitted to the electro-depositing bath. In melting the ingredients of the alloy, care has to be taken to prevent the volatilisation of the zinc.

Germans, St., a market-town of Cornwall, on the Fal, 9½ miles W.N.W. of Plymouth by the Cornwall Railway. It has a grand old church, with a Norman west front and towers, and in the vicinity is Port Eliot, the seat of the Earl of St. G. There is an export of coal and some fisheries. Pop. (1871) 2678.

German Tinder. See AMADOU.

Ger'mantown. See PHILADELPHIA.

Ger'many (Lat. *Germania*, Ger. *Deutschland*, Fr. *Allemagne*), in the wide ethnographic sense, is that portion of Central Europe which is occupied by the Germanic race and where the German language is spoken, extending from the Slavic E. to the Romanic W., and from the Alps to the North Sea and the Baltic. In the ordinary political sense—that with which we have now to deal—it comprises the greater part of this area as the German Empire, and is bounded E. by Russia and Austria; W. by France, Belgium, and the Netherlands; N. by the North Sea, Jutland, and the Baltic; and S. by Switzerland and Austria, in lat. 49° 7'–55° 50' N. and long. 6°–22° 40' E. It embraces one-eighteenth of the area of Europe, and is of irregular cuboid shape. Its extreme length from S.W. (about Aachen) to N.E. (Tilsit) is 740 miles, and from N. to S. 580 miles, while it has 1008 miles of a coast-line. The chief indentations in the N.W. are the estuaries of the Ems, Weser, and Elbe; in the Baltic, the Gulf of Lübeck, the Haff of the Oder, the Gulf of Danzig, and the Kurische Haff. The N. Frisian group off the W. coast of Slesvig, and Fehmern and Rügen in the Baltic, are the principal islands. G. consists of twenty-five states, the areas and populations of which are as follows according to the census of 1st December 1875 :—

States.	Area in sq. miles.	Pop. (1875).	Chief towns.
KINGDOMS—			
Preussen (Prussia, with Lauenburg)	134,431	25,772,562	Berlin.
Bayern (Bavaria)	29,138	5,022,904	Munich.
Würtemberg	7,527	1,881,505	Stuttgart.
Sachsen (Saxony)	5,785	2,760,342	Dresden.
GRAND-DUCHIES—			
Baden	5,910	1,506,531	Karlsruhe.
Mecklenburg-Schwerin	5,135	553,734	Schwerin.
Hessen-Darmstadt	2,963	882,349	Darmstadt.
Oldenburg	2,469	319,314	Oldenburg.
Sachsen-Weimar-Eisenach	1,403	292,933	Weimar.
Mecklenburg-Strelitz	1,131	95,673	New Strelitz.

Physical Aspect.—The surface of G. is naturally divided into three well-defined portions :—(1) The Alpine region in the S. with the Bavario-Suabian plateau stretching northwards; (2) the district of the German Mittelgebirge; and (3) the great sandy plain in the N. of G., which stretches E. and W. from Russia to the Netherlands, includes Slesvig-Holstein, and covers an area of 124,000 sq. miles. A branch of the Rhætian and Noric Alps forms the S. boundary of Bavaria and Würtemberg, sending northwards occasional offsets, but nowhere attaining the limit of perpetual snow, which is 8900 feet in the Alps. Of the ranges forming the Mittelgebirge, and converging more or less directly in the N. of Bavaria, are the Böhmer Wald (4800 feet), trending N.W. along the E. Bavarian frontier; the continuous chain of the Sudetic Mountains, Riesengebirge, and Erzgebirge (with the beautiful 'Saxon Switzerland'), forming the southern boundary of Silesia and Saxony; the Teutoburger Wald, Solling, Fichtelgebirge, and Thuringer Wald, extending S.E. in a somewhat broken line from the N. of Westphalia; the Rhöngebirge and Vogelsgebirge, from Hessen and Bavaria; and the Spessart and Odenwald, stretching N.N.E. from Baden, and connecting with the central chain the Schwarzwald (see BLACK FOREST) and the Suabian Alps. Several low ranges run at right angles to the Rhine in its lower course, chief of which are the Hunsrück, Eifel, Ardennes, Taunus, Westerwald, Siebengebirge, and Sauerländgebirge. The Rhine is enclosed on the side of Elsass by the Vosges (q. v.). The Harz Mountains (q. v.) are an isolated group (3470 feet), partly in Brunswick, Hanover, and Prussian Saxony. As the common affix *wald* implies, the mountains of G. are generally clad with forests, which give richness to the scenery and tone down the austerity of wild peaks and ridges. The great northern plain has an average elevation of 350 feet, while parts of the Slesvig-Holstein coast are below the level of the sea, protected by dykes.

Hydrography.—The rivers of G. are numerous, and have for the most part a northerly course. Of those entering the North Sea the principal are the Rhine, Ems, Weser and Elbe; the Oder, Vistula, Niemen flow into the Baltic. The great river of the S. is the Danube (q. v.), which rises in the Schwarzwald, some 40 miles N.E. of Lake Constance. The Etsch (Ital. Adige)

connects G. with the Adriatic. The Rhine is the longest river in G., the Weser the longest purely German river. There are many canals, of which the chief are the Elbing-Oderländisch, the Bromberger, Müllroser, Finow, Eider, Plauen, and Main-Donau or Ludwig's Canal. The lakes in the N. of G. are very numerous, but of no great size. The Spirding See and Mauer See, in Prussia Proper, are drained by the Pregel and Vistula respectively; the Plau, Malchow, Flesen, Kölpin, and Müritz, in Mecklenburg, by the Elbe and the Dümer. In E. Prussia the surface covered by lakes and marshes is 553⅛ sq. miles; in Mecklenburg, 255; in the Mark, 223; in Pomerania, 255. Besides Lake Constance, there are in the S. the Ammer, Würm, and Chiem Lakes, drained by affluents of the Isar and Inn.

Climate.—The climate throughout the empire is characterised by great uniformity, and is on the whole temperate and healthy. The S. Tyrol and the Rhine valley are the warmest parts, but the greater general altitude of S. than of N. G. counteracts the effects of a lower latitude. In the S., however, there is less rain and a clearer sky. Advancing N. the decrease of temperature is 1° F. in 52 miles; from W. to E. it is 1° F. in 72 miles. The mean annual temperature is at Hamburg 47° F., at Berlin 46·5°, at Hanover 48°, at Frankfurt-on-the-Main 48·5°, at Dresden 48°, and at Königsberg 43°. The mean temperature at Berlin in summer is 66° F., in winter 27°, or 3½ degrees lower than at London. Exposed to the cold winds of the N., the great northern plain is visited by severe winters, during which the ground is under deep snow for several months, and the water surfaces are covered with ice of great thickness. G. has a mean annual rainfall of 20 inches. There are eighty-five meteorological stations in the empire, mostly in Prussia.

Geology and Mineralogy.—The chief formations in the great northern plain are Tertiary, covered with mud and sand of a recent date, while the district stretching from Hanover to the Danube consists of Secondary strata. Primary beds, containing true coal, occur in Rhenish Prussia. The Trias rocks, of which the best types are bunter-sandstein, muschel-kalk, and keuper, are rich in fossils, marine shells, labyrinthodont saurians, &c. In the more recent Tertiary of the Lower Rhine basin have been found the bones of the mammoth, rhinoceros, &c. Westphalia and Central Germany are covered with Oolitic formations, confusedly erupted in many places by igneous rocks, and embracing much valuable coal and ironstone. Among the rocks of the Mittelgebirge are basalt, trachyte, granite, &c. The *minerals* of G. are numerous and valuable. In the Erzgebirge and Harz Mountains are rich mines of gold, silver, iron, copper, lead, salt, coal, alum, and sulphur. Coal and iron abound in Silesia, Rhenish Prussia, Elsass-Lothringen, Bavaria, Würtemberg, Hessen Darmstadt, &c. Other minerals exported are cobalt, arsenic, gypsum, bismuth, quicksilver, pumice-stone, kaolin, and emery. Immense deposits of pure rock-salt have been discovered near Stettin, in Pomerania. Along the Baltic coast valuable amber is obtained from beds of lignite in large quantities. Of the vast number of mineral springs in G. some of the most noted are those of Aachen, Wiesbaden, Ems, Selters Homburg, Kissingen, Rosenheim, Brückenau, and Baden-Baden.

Botany and Agriculture.—There are 50,000 sq. miles of wooded land in the whole empire. The large forests, which chiefly occur in the central mountain region and in the W. portion of the great plain, consist of elms, poplars, beeches, oaks, birches, pines, Scotch and silver firs, &c. The Black Forest is famed for its wealth of sombre foliage, and many of its trees are of gigantic size, some attaining a height of 180 feet. Of indigenous plants G. reckons some 7000 species, of which 2566 are flowering. Fruit-trees are extensively cultivated, and comprise the apple, pear, chestnut, plum, almond, walnut, apricot, &c. The vine is grown chiefly in Rhenish-Prussia, Nassau, and the Bavarian Palatinate; the best Rhenish wine is produced on the slopes of a ridge which extends in Nassau and along the right bank of the Rhine for 25 miles. Of German wines perhaps the best known is *hock*, which is distinguished by its delicate flavour and extraordinary durability. But other fine kinds are Asmannshaüser and Rüdesheimer. Among the cereals are rye, wheat, oats, and buckwheat; in the S. spelt, potatoes, maize. Elsass-Lothringen and Prussian Saxony yield much beetroot; the Rhine valley produces tobacco; while flax and hemp are most largely obtained from Baden, Hessen-Nassau, and Hanover. Other crops are saffron, madder, hops, rapeseed, poppy, anise seed, coriander and liquorice. The soil is for the most part fertile, and agriculture, for which there are various colleges, is in a thriving state. There are 102,115 sq. miles of surface under cultivation, 37,227 of meadows and pasture, and 17,944 of waste land; the most thoroughly developed parts being Prussian Saxony, Thuringia, Slesvig-Holstein, Posen, and Hessen. Husbandry engages some three-fourths of the inhabitants. There is abundance of excellent pasture.

Zoology and Live-Stock.—The forests of G. are still haunted by many wild animals, as the wolf, deer, hog, fox, lynx, martin, weasel, &c. In the Alpine S. are seen the eagle and vulture, while the northern plain (Pomerania) abounds in storks, wild-geese, ducks, &c. Bavaria is noted for pheasants and other kinds of game. Among domestic animals the chief are the horse in the N.; horned cattle (15,776,702) in the centre; sheep (3,352,231) mainly in Saxony, Silesia, Bohemia, and Thuringia; and swine (7,124,088) in Westphalia and Mecklenburg. Asses, mules (13,315), and goats (2,320,002) are also bred in large numbers; in the S. the silkworm is reared extensively, and the bee in the northern meadows. The rivers and lakes are rich in fish, of which the chief are the salmon, carp, trout, pike, perch, and eels. Crayfish, pearl-bearing mussels, and leeches are found in the rivers.

Industries.—The manufacturing industries of G., which have fluctuated greatly of late years, are mainly centred in Rhenish Prussia, Brandenburg, Westphalia, Prussian Saxony, and Silesia. The woollen industry employs some 250,000 persons, and causes an import of raw material amounting in 1873 to 1,088,700 cwt. To provide the cloth-factories with yarn, there are spinning factories with 1,750,000 spindles. Aachen is noted for its doeskins and other cloths, of which America takes 5,000,000 marks' worth yearly. In Greiz and Zeulenroda, the 'German Tibet,' the annual value of woollen stuffs produced is 20,000,000 marks. Apolda is noted for hosiery, Berlin for carpets and shawls, Schmiedeberg in Silesia for Turkey carpets. In the whole empire there are some 60 flax-spinning mills, with 280,000 spindles, and about 458,000 looms for the manufacture of linen, of which 250,000 are in the E. provinces of Prussia. The cotton industry, which is chiefly carried on in Elsass-Lothringen and Saxony, has greatly increased of late years, and in 1872 there were 430 mills, with 225,000 mills and 5,000,000 spindles. Silks and velvets, chiefly made in Crefeld, Elberfeld, Barmen, and Viersen, are exported in great quantity to Great Britain. The lighter velvets and half-silk goods are superior to those of France. Other branches of weaving industry are lace-making and embroidery in Saxony, galloons and fringes in Barmen and Berlin, and corset stuffs in Würtemberg. The valley of the Wupper is famed for its calico-printing and Turkey-red dyeing. Leather is an important manufacture in the S. and W., and among the exports are fine boots and gloves. Paper is made (chiefly near Aachen) in 950 mills, employing 25,000 persons. There are 3600 tobacco and cigar factories, in which 70,000 persons are engaged. Bavaria is famed for beer, while the N. German states alone have 10,220 breweries. G. has also 25,000 brandy-distilleries, 1600 vinegar-factories, 7000 oil-mills and refineries, 650 chemical works, 180 perfume-factories, 300 glass-works, 110 porcelain-factories, 18,000 brick-kilns, 10,000 saw-mills, and 5200 lime-kilns. In 1874 there were 336 beetroot-sugar factories, producing 5,640,700 cwt. of raw sugar. Berlin, Mühlhausen, and Chemnitz are the great seats of the machine manufacture (locomotives and sewing-machines), which is now conducted in 750 works, employing 90,000 hands. The iron and steel industries are chiefly confined to Prussia. The shipbuilding ports are Hamburg, Bremerhaven, and, for war vessels, Kiel, Danzig, and Wilhelmshaven on the Jade. Large ironclads are, however, procured from other countries. A specialty in G. is the manufacture of musical instruments—organs (at Dresden), harmoniums (at Gera), violins, pianofortes, &c. In the Black Forest watch-making employs 10,300 persons: other industrial products are musical boxes and straw goods. Typical manufactures of G. are also carved goods in bone, wood, meerschaum, mother-of-pearl, brass, bronze, and silver wares, and articles in vulcanite.

Commerce.—The trade and commerce of all G., except Hamburg and Bremen, are under the administration of the Zollverein or Customs' League, which is represented by a parliament, merged in the imperial Reichstag in 1871, and by a council of three permanent committees dealing separately with finance, taxes and customs, and trade. All receipts of the Zollverein, arising mainly from custom dues on imports and taxes on spirits,

wines, beetroot-sugar, and tobacco, are paid into a common exchequer, and are distributed equally among the various states *pro rata* of inhabitants. The total value of imports in 1874 was £188,655,000; of exports, £121,640,000. The direct imports from and exports to Great Britain in the same year amounted to £24,799,846 and £19,947,195 respectively. Among the exports are wheat, barley, flour, oxen, sheep, flax, timber, sugar, wool, and textiles. In 1875 the mercantile navy numbered 4495 vessels of 1,033,725 tons, 253 being steamers of 167,633 tons. There are some twelve trading ports.

Railways, &c.—In the beginning of 1876 the railways of G. open for traffic had a total length of 17,386 miles, of which 7463 belonged to the state. In 1875 there were 28,132 miles of telegraph lines, 101,422 miles of wires, and 5434 stations. The telegraph receipts amounted in the year ending March 1875 to £588,368, and the expenditure to £870,839. The imperial post-office in 1875 transmitted 576,013,557 letters, 64,662,503 post-cards, 9,302,611 patterns, and 92,956,908 stamped wrappers.

Finance.—The common imperial expenditure is defrayed from the revenues arising from customs, excise dues, and profits of the posts and telegraphs, and failing these, from an assessment on the various states in proportion to their populations. In 1876 the revenue was £23,712,849, and the expenditure £20,162,253. The £200,000,000 received as war indemnity from France was not entered in the budget, but was converted into a separate account by itself along with £6,000,000 indemnity from the city of Paris, and £14,000,000 from various French departments. Of this sum nearly one-half was portioned out among the states of the empire. The other half was disposed of in the following sums:—To France for the railways of Elsass-Lothringen, £13,000,000; to persons and corporations in Elsass and parts of G. for damage and expense sustained during the war, £5,505,000; similar compensation to shipowners, £840,000; for rolling-stock, &c., to the Elsass-Lothringen railways, £2,761,800; for the fortress of the empire, £6,000,000; to the Invalid Fund, £4,050,000; for extra expenditure incurred by the occupation, £4,350,000; and for the armament and disarmament of fortresses, the purchase of fresh siege material, and naval re-equipments, £4,200,000. Further a sum of £3,000,000 was repaid to the customs department, £1,650,000 went to liquidate treasury bonds, £525,000 were handed over to Bavaria and Würtemberg, whose military administration is not under the empire, £515,000 went to the imperial railway fund, £600,000 to generals as allowances, £6,000,000 was set aside as a war reserve fund, while the remainder was chiefly applied to the working capital of the imperial exchequer, and to several special branches of the military service.

Army.—By the constitution of April 16, 1871, the Prussian system of conscription was extended to the whole empire. Thus every German capable of bearing arms (*wehrfähig*) must pass three years in the line, three in the army of reserve, and five in the *Landwehr*—the support of the standing army. Substitution is not allowed, but teachers from the primary schools have only to go through infantry exercise for six weeks. Self-supporting volunteers, who pass certain examinations, only require to serve one year. The strength of the army on a peace footing was fixed, in the Army Bill of 1874, at 401,659 men, for a term of seven years beginning January 1, 1875. On a war footing the force can be raised to 1,273,346 men, with 31,195 officers, 281,546 horses, and 2700 guns. In 1875 the army consisted of 401,659 men, 18,079 officers, with 97,379 horses, and 1200 guns, in 148 infantry regiments, 26 battalions of Jäger, 93 regiments of cavalry, 36 of field artillery, 26 battalions of fort artillery, 19 of engineers, 18 of train, 274 depôts of Landwehr, and a staff division. By a law of 1874, the military strength was greatly augmented by the organisation of the *Landsturm*, which only becomes an active force in the event of invasion. It is divided into two classes, the first including all able-bodied men up to the age of forty-two who are not already in the army, the second embracing all fit subjects above that age. The first class is organised into 293 battalions, and adds 175,000 men to the army, so that, without the second class of the Landsturm, which, is not to be formed for the present, the German forces will be raised to some 1,800,000 men. The whole land forces 'form a united army in war and peace under the orders of the emperor,' and 'all German troops are bound to obey unconditionally the orders of the emperor,' who has the right of erecting fortresses, and of declaring a turbulent district in a state of siege.

Navy.—In November 1875 the navy consisted of 62 steamers of 80,580 tons, 70,340 horse-power, and 4268 guns. It comprises 3 turret-ships and 8 ironclad frigates, two of which, the *Kaiser* and *Deutschland*, launched in 1874, have ten-inch armour plate, and were built on the Thames. In 1875 the navy was manned by 5500 seamen, and officered by 1 admiral, 1 vice-admiral, 1 rear-admiral, 28 captains, and 224 lieutenants. There are also 9 companies of marines, 6 of infantry, and 3 of artillery, consisting of 1500 men. The crews are raised by conscription among the seafaring class. Wilhelmshaven, Kiel, and Danzig are the three war ports.

Constitution and Government.—The imperial constitution of April 16, 1871, binding together all the states of G., enacts an 'eternal union for the protection of the realm, and the care of the welfare of the German people.' The supreme control of affairs, military and political, is vested in the King of Prussia, who, as emperor, can declare war, if defensive, make peace, enter into treaties, and appoint and receive ambassadors. The legislature consists of the Bundesrath, or Federal Council of the individual states, and the Reichstag, representing the German nation. The former body numbers fifty-nine members, appointed for each session by the Governments of the different states; the latter 397 members, elected by universal suffrage and ballot for three years. The Bundesrath is presided over by the chancellor of the empire; the president of the Reichstag is elected by the deputies. All imperial laws before they take effect must receive an absolute majority of votes of both houses, and be assented to by the emperor and countersigned by the chancellor. The Bundesrath, under the direction of the chanceller, also exercises supreme administrative and consultative functions.

Education.—The educational system of G. is singularly comprehensive and complete, and since 1872 much has been done to counteract the effects of the obstructive policy adopted by the Ultramontanes. Ecclesiastics have been removed from the direction of schools in Prussia, Elsass-Lothringen, and several other states. Primary schools, of which there are 60,000, with 75,000 teachers, are maintained in all towns and villages out of local rates, and the attendance of children for four or five years is compulsory. A means of transition from the primary schools to the higher is furnished by middle schools of various names and organisations. The higher schools, over 500, are divided into *realschulen* and *gymnasia*. At the realschulen, modern languages, mathematics, Latin, and physical science, especially in its industrial applications, are taught; the gymnasia prepare for the higher government offices and the universities. In 1875 G. had twenty-one universities, with 1729 professors and 16,359 students. Of the universities fourteen are Protestant, *i.e.*, in the theological faculty teach only Protestant theology, while four are Roman Catholic. The remaining three are of a mixed character. There are many special schools for technology, agriculture, commerce, military science, music, design, &c. G. is rich in museums (over 150), art and science academies, picture-galleries, botanical gardens, &c. The press is free (since 1848), and from 8000 to 10,000 works issue from it annually. There are also some 3000 newspapers and journals, several of which have a high reputation beyond the empire.

Religion and Race.—While Protestantism prevails in the N., Roman Catholicism predominates in the S., but no state can be said to belong exclusively to either faith. The constitution of the Protestant Church varies in the different states. At the end of 1871 there were altogether 25,580,615 Protestants, 14,868,608 Roman Catholics, 49,351 (1876) Old Catholics, 512,158 Jews, some 82,155 Herrnhutters, Mennonites, &c. The Protestant Church has 16,000 clergy; while of the Roman Catholics there are 5 archbishops, 20 bishoprics, 3 vicariates-apostolic, 20,000 priests, and 800 monasteries. The Jesuits were excluded from the territory of the empire July 4, 1872.

In 1871 the population of the empire, exclusive of 80,000 foreign residents, comprised 37,820,000 Germans, 2,450,000 Poles, 140,000 Wends, 50,000 Czechs, 150,000 Lithuanians and Kurlanders, 150,000 Danes, and 220,000 French and Walloons.

History.—On the breaking up of the Roman empire, the Germanic tribe of the Franks (q. v.) founded a kingdom partly in N. Gaul and partly in what is now G., which was ruled by the Merwing princes. The Franks who remained by the Rhine, however, became severed from the

Frankish settlers among the Gallo-Romans, and in the middle of the 8th c. the purely Germanic kingdom of Austrasia held sway under the Karolings (q. v.) over the rival Gallicised kingdom of Neustria (see FRANCE, HISTORY OF). When Karl the Great was made Emperor of the Romans, the Karoling power was at its highest, Karl ruling over the lands from the Eider to the Tiber, and from Hungary to the Pyrenees. But this great Teutonic empire was dismembered by the treaty of Verdun (843), when the kingdom of the W. Franks or France was separated from the kingdom of the E. Franks or G. These realms were reunited under Karl the Fat, and permanently severed on his death in 887. The House of Capet now became kings of N. France, while the Karolings ruled E. Franconia, which corresponds loosely to modern G., until 911, when the line became extinct. The most lasting work of Karl the Great was to give something of unity to G., but the land still preserved its tribal distinctions in the great dukedoms of Saxony, Franconia, Suabia, Lotharingia, and Bavaria. Konrad, Duke of Franconia, was chosen king by the great nobles, who now seized the right of electing the monarch, and on Konrad's death in 918, Heinrich the Fowler, Duke of Saxony, was appointed his successor. Heinrich, the founder of the Saxon dynasty, warred victoriously against the Magyars, and strengthened the royal power against feudalism. His son, Otto the Great, again united the offices King of G. and Emperor of Rome. Up to this time the imperial throne had not been specially connected with any kingdom, having been in theory open to all Christian freemen, and having been filled by rulers of various countries. Now, however, it was acknowledged that the King of G. had a right to be crowned King of Italy at Milan and Emperor at Rome. Under Otto's successors the Popes shook off their old dependence on the Empire, and the royal power sank, while the feudal and ecclesiastical power increased, but Konrad I. of the Franconian line (1024–1039) revived the kingly authority, enforced order, and checked the Papal pretensions. Heinrich III. (1039–1056) continued to increase the extent of the royal power, but under his successor, Heinrich IV., strife and confusion ensued, Pope Hildebrand opposing Heinrich with unflinching determination, and stirring up the feudal barons to revolt. In 1137 the first of the Hohenstaufens, Konrad III., became king, and in the reign of his son, Friedrich Barbarossa (1152–92), Italian politics began greatly to influence German history. The Guelphs and Ghibellines (q. v.) had now arisen, and the emperors were called on for help by the small Guelphic commonwealths. The evil effects of the imperial dignity on G. now became manifold. It led the emperors to interfere in Italian politics, to waste their strength on fruitless Italian expeditions, and neglect their own and their people's interest; it drew them into strife with the Popes, who inflamed the German barons against them at home. After the death of the great Friedrich II. (1212–50), whose reign was mainly occupied in warring with the Pope, the imperial power sank, succeeding emperors having almost no direct influence beyond G., where their power was steadily shrinking. Meanwhile numerous Free Cities (q. v.) had arisen; the commerce of G. had greatly increased; and, especially under the Hohenstaufens, many serfs had won liberty by the Crusades and by flying to the towns. Unfortunately there was little advance in national unity and constitutional freedom. The Diet, a faint shadow of the old Teutonic assemblies, was an aristocratic, not a national, body. While in France feudalism destroyed the old Teutonic institutions, and so cleared away all constitutional checks on monarchy, in G. feudalism changed the old institutions into oligarchical tools for breaking up the country and lessening the royal power. In the 12th c. the right of choosing the king was confined to the seven chief princes called the Electors (q. v.). On the death of Friedrich II.'s son, Konrad IV., in 1254, the line of Hohenstaufen emperors ended. Up to this time the Empire had been partly elective, partly hereditary. Henceforth a time follows in which birth is almost ignored, until the middle of the 15th c., when Austrian princes began to be regularly chosen. From 1254 G. had no actual king until 1273, this period, one of terrible suffering and anarchy, being known as the *Great Interregnum*. In 1273 Rudolf, Count of Hapsburg in Suabia, was made king. He was a brave, well-meaning, and able ruler, and, aided by the Church and people, curbed the robber-barons and vindicated the civil power. Rudolf's son, Albrecht, becoming Duke of Austria, the electors, jealous of Austria, made Heinrich, Count of Lützelburg or Luxembourg, king. He was the first German monarch crowned emperor since Friedrich II. After Heinrich's death civil war raged between Ludwig of Bavaria and Friedrich Duke of Austria, the towns mostly supporting the former, and the nobles the latter. Ludwig finally became king, and was succeeded in 1347 by Karl IV., who in 1356 published the *Golden Bull* (q. v.). The reign of his son Wenceslaus (1378–1410) was marked by the beginning of the Hussite movement, and by the fierce struggles between the towns and the nobles, both parties uniting in leagues or confederations. The Femgerichte (q. v.) now grew vastly in power, and the Hansa League was very thriving. In 1410 Siegmund, King of Hungary, was made king, and in 1433 emperor, his reign being the beginning of the particular connection between the empire and Hungary which afterwards had a grave influence on German history. Siegmund strove to reform the Church, and died in 1437. The emperor's office had now become an almost empty honour, and it was necessary to elect a prince to it who held power independent of his imperial position. The emperor was no longer recognised as the overlord of Europe; and the Empire was held from the time of Albrecht II., Duke of Austria (1437–38), to 1806 by princes of the House of Austria. The last emperor crowned at Rome was Friedrich III. (1440–93). His son, Maximilian, did something to further justice by dividing G. into circles, and appointing the special court known as the *Imperial Chamber*. Meanwhile feudalism and the system of chivalry were vanishing, the princes and great nobles having after the introduction of gunpowder begun to carry on war with mercenaries (*Landsknechte*), instead of exacting military service from their vassals. During Maximilian's reign the Reformation began to agitate G., and in the time of Maximilian's successor, Karl V. (1519–56), spread rapidly through the land. (See REFORMATION.) On the death of Karl V. his empire, which included G., Austro-Hungary, Spain, Holland, Belgium, and parts of Italy, was broken up, and G. went to Karl's brother, Ferdinand I. (1556–64). The religious differences finally resulted in the Thirty Years' War (q. v.), which lasted from 1618 to 1648. It was carried on between the Protestant princes of G. and the Emperor Ferdinand II. The emperor at first seemed about to crush the German Protestants, but the victories of Gustavus Adolphus restored the fortunes of the former; and the subsequent espousal of their cause by France changed a religious into a political struggle, which was ended by the peace of Westphalia in 1648. G. was terribly enfeebled by the long strife. Half, if not more, of her people had perished in the intestine fighting. The land was almost untilled, and many of the towns were in ruins. All national feeling seemed dead, the differences of creed which arose at the Reformation tending strongly to split up the country. Henceforth, until recently, G. was merely a loose cluster of petty states ruled by despots or oligarchs over whom the emperor had no control, while the Diet of the Confederation which sat permanently after 1654, and nominally held the rights formerly belonging to the emperor, of making war and peace, passing laws, &c., was never powerful, and became notorious for its formal trifling. After the war G. continued to sink into degradation. The Diets of the various states were mostly abolished; the Free Cities, no longer united in leagues, lost their old political influence, while many of them fell into the hands of the small princes, who pursued a purely unnational policy, and aped the luxury and sensuality of the French court. Louis XIV. of France, taking advantage of the weakness of G., in a time of peace, in 1687, seized the free city of Strassburg, and in 1689 ravaged the Palatinate. The German princes, instead of uniting together, partly sided with Louis, who had more power in G. than belonged to the emperor. Towards the end of the 17th c. Prussia began to rise under the Electors of Brandenburg, and in 1701 was declared a kingdom independent of Poland. Friedrich Wilhelm I. and Friedrich the Great built up the power of Prussia by able government, thrift, and thorough military organisation, while the other German princes wasted the strength of their territories in shameful prodigality and selfish jealousies. After the Seven Years' War (1756–63) (see SEVEN YEARS' WAR and FRIEDRICH II.), Prussia and Austria remained rivals for the mastery over the various German states. In 1777 the Emperor Joseph II. sought to annex Bavaria, but was hindered by Friedrich the Great. Joseph was succeeded by his

brother Leopold, who was followed by Franz II., the last of the Austro-Germanic emperors. Austria and Prussia united against France at the time of the French Revolution, and were both humbled in the wars of Napoleon. By the peace of Luneville (1801) all G. left of the Rhine was joined to France; and after Prussia and Saxony were crushed at Jena (1806), the states of Southern G. were united into the Confederation of the Rhine (q. v.), under Napoleon's protectorate. A kingdom of Westphalia was set up under Jerome Bonaparte, and finally North-Western G., with the free cities Lübeck, Bremen, and Hamburg, was added to France. In 1813 came the great rising of G. against Napoleon, and after the battle of Leipsic the Congress of Vienna (1814-15) made a new settlement of German affairs. The boundaries of the states were all shifted; many of the smaller states were absorbed; the kingdoms of Würtemberg, Saxony, and Bavaria, which Bonaparte had created, were suffered to remain; but much of Saxony was added to Prussia. No strong federal principle allied the petty states, for the supremacy over which Prussia and Austria soon reappeared as rivals. The princes broke their promises to form constitutional governments, and until 1848 Metternich, the Austrian Minister, held the chief authority throughout G. There had arisen, however, a fervent national sentiment, an eager wish for union and progress, which was strengthened by Prussia establishing the commercial union of the *Zollverein* in 1833. The members of this union, of which Prussia was the centre, and which was joined by most of the German states, agreed not to levy duties on merchandise passing from one state to the other, an arrangement which did much to prepare the country for political unity. After the revolutions of 1848 in Prussia, Austria, and other states, a fruitless effort was made to form a German empire and a great German parliament. G. seemed about to relapse into her old condition, when, in 1863, Bismarck, the Prussian Minister, inaugurated a new policy, by wrenching Slesvig and Holstein from Denmark. In 1866 war broke out between Prussia and Austria, and the Austrians, utterly beaten at Sadowa (1866), were forced by the peace of Prague to withdraw altogether from the German confederation. The North German states were then formed into the North German Confederation under the presidency of Prussia. Still the union of G. seemed doubtful, until it was unexpectedly brought about by the Franco-Prussian war, which was provoked by Napoleon III.'s jealousy of Prussia and hope of redeeming his lost popularity. The French emperor also expected that the S. of G. would aid him or remain neutral, but all G. supported Prussia. On August 2, 1870, the first encounter took place at Saarbrücken, when the French gained a trifling success. Then the Germans, winning the victories of Weissenburg (4th Aug.) and Wörth (6th), advanced with about a million of men to the Moselle, and defeated the French at Vionville and Gravelotte. Bazaine, who had taken chief command of the French, was now hemmed in at Metz, and Macmahon, while marching to relieve him, was beaten at Beaumont, after which the French were driven from different sides into Sedan, where Napoleon III. surrendered with 90,000 men, September 4, 1870. On September 5 the Germans began the siege of Paris, the French vainly striving to break their lines. The army of the Loire was now formed, and Faidherbe raised a force in the N. But Bazaine surrendered with 180,000 men on October 17, and the army of the Loire was driven back from Paris, and divided into two divisions under Generals Chanzy and Bourbaki. Chanzy's force was soon dispersed, but Bourbaki marched towards Southern G., which he seriously endangered, until he was checked at Hericault, and finally forced across the Swiss frontier on February 1. On January 18, 1871, King Wilhelm was proclaimed, at Versailles, German Emperor, the North German Confederation having been changed into the German Confederation. Faidherbe, who had struggled with great ability, was beaten at St. Quentin on January 19, and on January 28 Paris surrendered. The preliminaries of peace were signed on February 26, and on May 10, the peace of Frankfurt was concluded, by which France ceded Alsace and Lorraine, and agreed to pay 5,000,000,000 francs. The present German empire includes twenty-five states, which retain considerable local privileges. The executive power rests with the emperor, the legislative with the Diet and Federal Council. The present empire is not a revival of the Holy Roman Empire. That was a medieval restoration of the Roman Empire, while the new imperial office partly represents the old dignity of 'King of the Germans.'

See Menzel's *Geschichte der Deutschen* (8 vols. 1815-22), and *Neuere Geschichte der Deutschen* (12 vols. 1826-48); Luden's *Geschichte des Deutschen Volks* (12 vols. 1825-39); Wenzel's *Geschichte der Deutschen* (5 vols. 1855); Mayer's *Deutsche Geschichte* (2 vols. 1858); and Giesebrecht's *Geschichte der Deutschen Kaiserzeit* (1862-68).

German Language and Literature. *Language.*—The G. L. is a branch of the Teutonic family of Aryan speech, as is illustrated by the Germans still calling it *Deut-sch*, the name *German* having probably been given by some Continental Celts. Greek and Latin authors supply incidentally the only specimens of Germanic speech preserved from heathen times; but after the diffusion of Christianity several of its dialects gradually began to be moulded through popular translations by the clergy of prayers and ecclesiastical formularies. At least 300 years earlier than any of these MSS. is the unique translation of the Bible into Gothic by Bishop Ulfilas (318-388), highly interesting as affording the groundwork of the history of the language. Already in the 7th c. we find the Germanic dialects divided into two main sections, the Upper or High German, and the Lower or Plain (*Platt*) German, separated then as (generally speaking) now by a line roughly drawn from the mouths of the Ruhr and Sieg to the Harz, the High German being subdivided into the pure Upper German (or South German) and the Middle German (to which belong the Upper Saxon and Franconian dialects); and the Plain or Low German (spoken in the western part of the N. German lowland, *i.e.*, N. of a line drawn through Aachen, Bonn, Cassel, Nordhausen, and Wittenberg) into the Lower Saxon (in Holstein, Mecklenburg, and part of Brandenburg and Pomerania) and the Westphalian.

High German eventually prevailed over Low German, and in the form known as *Old High German* flourished for six centuries, from the foundation of the Frankish dominion (about 500 A.D.) to the beginning of the Crusades (1096), a period in which, Latin being the recognised medium of the court, the clergy, and the learned and cultured classes generally, the native language was confined to popular religious literature and some popular songs. The influence of the Crusades, of the spirit of chivalry, and of the new relation to Italy, &c., resulted in greater breadth and freshness of ideas, and created a new era in the national mind, which found fitting expression in a great chivalrous court poetry in *Middle High German*, a form at first used by the nobles and princes, but gradually by the people as well. As this poetry soon diffused itself throughout Germany, it speedily lost all provincial peculiarities, till at last the Swabian dialect, used not only at court, but by the best and most poets, predominated over the rest, and was employed by writers of Low German or even wholly alien origin. But as literature and art sank with the fall of the House of Hohenstaufen, so also the language received much injury. The dialects again gained the mastery; alike in speech and writing arose a bewildering confusion, until at length the Upper Saxon dialect rose above the rest, and won a greater than common diffusion. This Luther employed in his translation of the Bible and in his other writings, and through him the *New High German* form by degrees extended its dominion over all German literature; being destined, despite foreign corruption (against which Opitz, &c., fought persistently) and the well-nigh ruinous influence of the Thirty Years' War, to become the final exponent of all writers and men of culture. Gottsched laid the foundation for a coherent treatment of the grammar, and the G. L. came constantly nearer to its highest development and polish in the hands of Klopstock, Lessing, Wieland, Herder, Goethe, Schiller, Winckelmann, Kant, &c. The influence of translations, in which Voss was the first master, as well as of the study of the writings transmitted from antiquity and the middle ages, was very marked. Benecke was the founder of such philological study, but it received its greatest impetus from the labours of the brothers Grimm in early Germanic language and history, and the philological criticism of *Old High German* by Lachmann, the discoverer of its metrical laws. The most noteworthy followers of these have been Gabelenz, Schulz, Diefenbach, Graff, Schmeller, and Wackernagel. The grammar has also been treated philosophically by Becker (K. F.), Herling, &c. See Wackernagel's *Deutsches Lesebuch*; Pischon's *Denkmäler der Deutschen Sprache* (1838-51); *Germaniens Völkerstimmen* (1843, *et seq.*), by Firmenich; Bernhardi's *Sprachkarte von Deutschland* (2d ed. 1849); Grimm's *Geschichte*

der Deutschen Sprache, and *Deutsche Grammatik* (Göttingen, 1819-40); Bopp's *Comparative Grammar;* Bessel, *Ueber das Leben des Ulfila;* Max Müller's *Science of Language* (1861-64); Helfenstein's *Comparative Grammar of the Teutonic Languages* (Lond. 1870); Schleicher's *Compendium der vergleichenden Grammatik der Indo-germanischen Sprachen* (Weimar, 1866); Whitney *On Language* (3d ed. 1870).

Literature.—I. *From the Earliest Times to* 1200.—Unlike English and French literature, G. L. has had no continuous growth, and its chief works belong to very recent times. The wild pagan war-songs and mythic tales died out after the time of Karl the Great under the influence of Christianity, and the brood of Latin hymns, prayers, and paraphrases which took their place had no literary vitality. Of the pieces on Christian subjects, the best was *Heliand*, written in Low German in the 9th c. by an Old-Saxon poet. Except Eginhard (q. v.), the biographer of Karl the Great, there was scarcely a German author of European reputation before the 13th c., the period of the *Minnesänger* ('love-singers'). II. 1200-1300.—The *Minnesänger* poetry was awakened partly by the *Troubadour* and *Trouvère* songs and epics, partly by the influence of the Crusades, and centred in the brilliant Suabian court. Among its chief writers were Walther von der Vogelweide (q. v.), Wolfram von Eschenbach (q. v.), Gottfried von Strassburg (q. v.), Konrad von Würzburg (q. v.), Hartmann von Aue, Heinrich von Ofterdingen, Hugo von Trimberg, &c. They wrote lyrics, generally musical and joyous, though somewhat monotonous in their praise of love, chivalry, and the spring-time, and long ballads resembling the *Chansons de Geste*, celebrating the deeds of Arthur, Roland, and Charlemagne. Meanwhile the old heathen and heroic poetry lingered in popular ballads sung by wandering minstrels; and in this period a number of these old lays were gathered together into the *Heldenbuch* ('Book of Heroes') and the great national epic of the *Nibelungenlied* (q. v.). Besides the gay, sentimental, knightly poetry, there arose a comic, mocking literature, best represented by *Reinaert de Vos*, the famous satirical allegory translated from Flemish into German in the 12th c. III. 1300-1600.—The *Minnesanger* poetry declined on the fall of the Hohenstaufen dynasty, which had fostered it with genial patronage, and died out in the 14th c. Meanwhile the burgher class had been rising in power, and a new literature of stories, fables, and satires, sometimes blunt and clumsy, sometimes coarsely pungent, and essentially *bourgeois* in style and sentiment, was created. The comic drama began to develop from the medieval theatre (see MIRACLE PLAYS and DRAMA), and in the 15th c. the great schools of the *Meistersänger* were formed. The *Meistersanger* were wholly popular, as the *Minnesanger* were purely aristocratic poets. They were mostly artisans who sang the praises of their various crafts, and united into Guilds (q. v.) to compose and recite verses. The most famous of the *Meistersanger* was Hans Sachs (q. v.), and the most famous guilds were in Ulm, Mainz, and Nürnberg. In the 15th c. the Renaissance learning entered Germany, and the Greek and Latin classics began to be studied. A new freedom of thought followed on the studies of the humanists, and spread down to the people, who delighted in satirical and facetious tales, such as *Eulenspiegel* (q. v.), and the *Narrenschiff* of Brandt (q. v.). The chief writers of the early Reformation times were Luther (q. v.), Ulrich von Hutten (q. v.), and Fischart (q. v.). Other authors of the 16th c. are Schede, Knaust, Ringwaldt, Beltz, Metzger, Hager, and Denaisius. IV. 1600-1700.—The 17th c. was the darkest period in G. L. Poetry withered amid the dull dogmatic strifes that followed the Reformation, and is found almost solely in the religious hymns. At length literature was for a time almost extinguished by the Thirty Years' War. Martin Opitz (q. v.) established a new theory of German verse, and founded the First Silesian school, which included Flemming (q. v.), Gryphius, Van Zesen, and Gerhardt (q. v.), and aided to polish and purify the speech, but which by its slavish imitation of the French *classical* writers sank into empty affectation. A reaction against this Gallicising tendency began with the Second Silesian school, which, led by Hofmann von Hofmannswaldau and Kaspar von Löwenstein, substituted frantic bombast and exciting plots for the insipidities of Opitz's followers. V. 1700-1770.—During the first half of the 18th c. the language became more copious and nervous, and English began to displace French authors as literary models. Gottsched (q. v.) assailed the sterile mimicry of the Second Silesian school; and with Klopstock (q. v.), Lessing (q. v.), and Wieland (q. v.) a national imaginative literature arose, not yet, however, fully emancipated from the 18th c. classical style. Among other writers of this period were Haller (q. v.), Bodmer (q. v.), Breitinger, Gessner (q. v.), Gellert (q. v.), Lichtwer, Gärtner, Giseke, Kreuz, Weisse, Hagedorn (q. v.), Kramer, Gleim, Ramler, &c. Lessing inaugurated a national drama; Klopstock taught the Germans to sing the praises of the 'Fatherland;' Wieland introduced a fresh and natural gaiety and lightness of thought and style; and Winckelmann (q. v.) began a new era in the history of æsthetic criticism, and disclosed the true nature of Greek art and culture. VI. 1770 *to the Present Time.*—This is by far the richest period of G. L. alike for the number, beauty, and originality of the works which belong to it. Henceforth German writers, instead of wrangling over the respective merits of French or English writers, and feebly aping French polish and clearness, began to give voice to their nation's sentiments, to create an impassioned, unimitative literature. This last period may be subdivided. From 1770 to 1794 is the *Sturm-und-Drang Periode* ('Storm-and-Pressure Period'). A wildly violent reaction arose against the old 'classical' schools, and poems full of strained rhapsodies and furious passion, but foreshadowing a more free and varied literature, were written by Stolberg (q. v.), Heinse, Müller (q. v.), Klinger (q. v.), Lenz (q. v.), Burger (q. v.), and Goethe (q. v.). But this period, with its pathos and weirdness, its stormy novelties and grotesque rant, passed swiftly away; G. L., guided to new and lofty issues by Goethe and Schiller (q. v.), became purified from the *Sturm-und-Drang* excesses, and along with vivid energy and passion revealed an unlooked-for beauty of execution. About this time the German Romantic school arose, a school comprising poets, critics, and historians, and of which the leading features were a somewhat exaggerated love for nature, an intense fondness for medieval themes, an enthusiastic worship of Shakespeare, a sentimental and mistaken admiration of the middle ages, and a general tendency to a glowing, dreamy, and fantastic style. To the earlier Romantic school belonged the brothers Schlegel (q. v.), Wackenroder, Tieck (q. v.), and Novalis (q. v.). After 1813 the War of Liberation called forth a number of patriotic poets, as Körner (q. v.), Rückert (q. v.), and Schenkendorf (q. v.); but the Romantic school, swayed by medieval predilections, began to show reactionary tendencies in politics. The later Romantic school was devoted mainly to weird, fanciful, and florid prose romances, and included Fouqué (q. v.), Arnim (q. v.), Brentano (q. v.), Eichendorff, and Hoffmann (q. v.). The first half of the 9th c. is the golden age of G. L. The masterpieces of Goethe and Schiller moulded the national taste anew, and a magnificent poetry was created, wonderfully many-sided, profound, and passionate, expressing with almost unequalled subtlety and power the philosophical questions and political aspirations characteristic of modern times, and especially remarkable for the number and beauty of its lyrics. These have not in general the sunny blitheness of the old *Minnelieder;* they are mostly steeped in pathos, and clouded by mystical suggestions, and have an endless charm in the melodious flow and haunting melancholy of their rhythm. Goethe united the variety, glowing colour, and deep subjectivity of the Romantic with the breadth, repose, and transparency of the Classical spirit, but, notwithstanding his vast influence, both the Romantic and Classical tendencies have recently given place to a strong realistic movement, which in a measure discards the Classical polish as well as the whimsical Romantic fervours. Alongside of the magnificent poetry of the 19th c. a great prose literature grew up, represented in history by Muller (q. v.), Schlosser (q. v.), Ranke (q. v.), Niebuhr (q. v.), Menzel (q. v.), Dahlmann (q. v.), Droysen (q. v.), Gervinus (q. v.), Mommsen (q. v.), &c.; in philological criticism, by Bopp (q. v.), the brothers Grimm (q. v.), Adelung (q. v.), the Humboldts (q. v.), Wolf (q. v.), Hermann (q. v.), Heeren (q. v.), Heyse (q. v.), Steinthal (q. v.); in theology, by Schleiermacher (q. v.), Neander (q. v.), Bunsen (q. v.); in philosophy, by Kant (q. v.), Fichte (q. v.), Jacobi (q. v.), Hegel (q. v.), Schopenhauer (q. v.), Feuerbach (q. v.), Stahl (q. v.), &c. In fiction the chief names are Richter (q. v.), Börne, Hoffmann (q. v.), Mundt, Sternberg, Freytag (q. v.), Gerstäcker (q. v.), Heyse (q. v.), Grimm (q. v.), Auerbach (q. v.), &c. The foremost poets, not yet mentioned, from 1813 to the present time are, in lyrical poetry, Heine (q. v.), next to Goethe perhaps the greater German lyrist, Platen (q. v.), Spitta, Uhland (q. v.), Herwegh, Geibel (q. v.), Grün, Lenau, Schneckenburger, Kinkel, Hartmann, and Gottschall; in the

drama, Halm, Hebbel (q. v.), Freytag, Gutzkow, Ludwig. An important element in G. L. is the innumerable number of *Volkslieder*, or popular songs by unknown authors, which are mostly instinct with the tenderest melody and a strange old-world charm, couched in exquisitely simple language, and, like the early *Minnelieder*, bright with fresh vivid descriptive touches. See Gervinus' *Geschichte der Deutschen Dichtung* (5th ed. 1871); Koberstein's *Grundriss der Deutschen National-Lit.* (1845); Vilmar's *Vorlesungen über die Gesch. der Deutschen National-Lit.* (4th ed. 1851); Gruppe's *Leben und Werke Deutscher Dichter* (1861–68); Schmidt's *Gesch. der Deutschen Lit.* (5th ed. 1865-67); Gottschall's *Die Deutsche National-Lit.* (3d ed. 1871).

Ger'men, or **O'vary**, the name for the lower portion of the Pistil (q. v.), or central part of a flower, which ultimately becomes the Fruit (q. v.). It contains the young seeds or Ovules (q. v.). The G. is said to be *superior* when the other parts of the flower are placed below it, as in the lily; and *inferior* when the parts are placed above, as in the gooseberry.

Ger'mersheim, a town of Rhenish Bavaria, at the confluence of the Queich and the Rhine, 8 miles S.S.W. of Speyer. It has some trade in corn, hemp, flax, &c. Pop. 10,180. G. was originally a Roman fortress and station. A 'burg' was built here by Konrad II., but the place first emerges as a town in the time of Rudolf of Hapsburg, who died at G. in 1291.

Germina'tion, the term applied to the sprouting or beginning of growth of the young plant in the seed. Certain conditions are essential to G., such as moisture, heat, and air. Darkness is also favourable. Internal changes take place in seeds during G. Starch is converted into dextrine or sugar by oxidation, and diastase is developed. During these changes considerable heat is evolved, and substances which were before insoluble become soluble. The seed becomes swollen; the embryo enlarges, ruptures the integument, and protrudes; and the growth of a new plant commences.

Germ Theory of Disease. Various theories have been adduced regarding the mode by which diseases of the contagious and infectious type gain entrance to the body and produce their pathological effects. Two centuries ago the celebrated Robert Boyle said 'that he that thoroughly understands the nature of ferments and fermentations shall probably be much better able than he that ignores them to give a fair account of divers phenomena of several diseases (as well fevers as others), which will perhaps be never properly understood without an insight into the doctrine of fermentation.' The prediction of Boyle has been verified; for the recent exhaustive observations, by aid of the microscope, of the process of Fermentation (q. v.) have been the foundation of the G. T. of D. The air contains numberless germs that act as ferments when brought into contact with a medium suitable for their development, some of them producing alcohol, some acid, and others putrefaction. When pure meat is exposed to the air, it becomes, after cooling, either sour or putrid, and on microscopic examination, that which is sour is found to be swarming with organisms called *vibrio*, and that which is putrid with *bactria*. Reasoning from such data, Professor Lister of Edinburgh inferred that the putrefaction of wounds might be arrested by the destruction of the *bactria*, and to effect this, he introduced the antiseptic system of treating wounds, the most important advance ever made in surgery. The most striking analogy between a *contagium* and a ferment consists in the power of self-multiplication possessed and exercised by both; for a particle of *contagium* may spread through the body and be so multiplied as to decimate whole populations. In 1850 MM. Davainne and Rayer made observations on the blood of animals which died of splenic fever, and discovered small microscopic organisms resembling transparent rods. Some time afterwards a German physician, Koch, studied the habits of these organisms, and his observations were confirmed by the celebrated naturalist Cohn of Breslau. The rod-like organisms, when placed in a drop of the aqueous humour of the eye, began to lengthen, and in a few hours they formed filaments a hundred times the length of the original rods. Within the filaments little dots appeared, gradually becoming more and more numerous and distinct until the whole organism was studded with them, being converted into a long row of seeds or spores. Koch proved, by actual experiment, that the spores as distinguished from the rods constituted the *contagium* of splenic fever. According to the G. T. of D. many diseases, but particularly those of the contagious and infectious class, depend for their development on similar principles, and each specific disease has its peculiar germ or seed. The nature of the morbid action depending on the enormous multiplication of the germs within the body is merely in process of investigation; but as regards specific fevers it is probable that the characteristic features of the febrile state are due to the growth of the germs or contagious particles, and that the disturbance to which they give rise results from the appropriation by them of the essential constituents of the blood, rather than from any special action as poisons which they may possess. See *The Germ Theory applied to the Explanation of the Phenomena of Disease: The Specific Fevers*, by T. Maclagan, M.D. (Lond. 1876, Macmillan & Co.).

Gerôme, Jean-Léon, a great French painter, was born 11th May 1824, at Vésoul, Haute-Saône, went to Paris and became a pupil of Paul Delaroche and a student at the Fine Arts School in 1841. He travelled in Italy with Delaroche in 1844, and studied and sketched in Turkey and Egypt from 1853 to 1856. Since 1847 G. has produced an immense number of pictures, some of which, as the 'Gladiators before Cæsar—*Ave, Cæsar Imperator, morituri te salutant*,' and the 'Death of the Vanquished Gladiator—*Pollice Verso*,' are almost too absorbing and painful in the character of the interest they excite. Other great works are 'Bacchus et l'Amour' (1848); 'Le Siècle d'Auguste et la Naissance de Jésus Christ' (1855); 'La Sortie du Bal Masqué,' and 'Memnon et Sesostris' (1857); portrait of Rachel, and 'Phryne devant le Tribunal' (1861); 'Louis XIV. et Molière,' 'Cleopatra et Cæsar (1866); 'La Mort de Cæsar (1867); 'Promenade de Harem' (1869); and the wall painting 'La Peste à Marseille' in one of the chapels of Sainte-Séverin. G. is well known through photography. His works, often sombre and even sinister, are always highly imaginative and instinct with a sensuous dramatic life. He combines the traits of the Romantic and Classical schools. In 1878 G. was made a Commander of the Legion of Honour.

Gero'na, a city in the N.E. of Spain, capital of the province of the same name, 60 miles N.N.E. of Barcelona, with which it is connected by rail. It stands on the Ter, near the foot of the Gavarras Mountains. Its streets are narrow and picturesque; it has a large collegiate church; and its Gothic cathedral, begun in 1316, is one of the finest and most original of medieval buildings. G. is enclosed by massive walls, and defended by four forts. There is some trade in soap, leather, cotton, and wool. Pop. 14,615. G., the *Gerunda* of the Romans, was made the see of a bishop in 786, was the residence of the Aragonese kings, and is said to have sustained twenty-eight sieges, the most famous being that of 1809, when it held out for above seven months against the French.

Gers, a department in the S.W. of France, is named from the river G., which traverses it from N. to S., and is bounded N. by Lot-et-Garonne; S. by the Hautes and Basses Pyrénées; E. by Haute-Garonne and Tarn-et-Garonne; and W. by Landes. Area, 2425 sq. miles; pop. (1872) 284,717. It is entered in the S. by six parallel offshoots of the Pyrenees, but extends in a flat fertile plain in the N., watered by the G., Adour, L'Osse, Baise, Arratz, Gimone, and Save. There are several forests. Wine is produced to the extent of 20,000,000 francs, but is mainly used for making Armagnac brandy, which is exported largely to N. America. At the last census G. had 298,000 sheep, 145,000 cattle, 56,000 pigs, and 6000 mules, reared mainly for the Spanish markets. Auch is the capital, and the terminus of the Agen-à-Auch Railway. The patois of G. is a mixture of Gascon and the Langue d'Oc.

Ger'son, Jean Charlier de, a great medieval theologian, was born at Gerson in the diocese of Rheims, December 14, 1363, and studied at Paris University, of which, in 1395, he became chancellor. He earned a wide fame as a scholar and the surname 'Most Christian Doctor,' and laboured sedulously to end the Great Schism, urging that the two (and afterwards the three) rival Popes should resign. In 1414 he figured in the Council of Constance, and sullied his character by advocating the burning of John Huss. A warm champion of the Orleanist or national party in France, G. denounced the Duke of Burgundy for the murder of the Duke of Orleans, and the resentment of the great noble forced him to quit France and wander as a pilgrim over Germany. He was kindly welcomed by the Duke of Austria,

and spent some time at Vienna, returning to France after Burgundy's death, in 1419. G. spent his last years within the Celestine monastery at Lyon, where he died, July 12, 1429. He was a Nominalist and strictly orthodox theologian, but denounced the worldliness and license of the Popes. Among his works are *De Consolatione Theologiæ*, partly in verse, and imitated from the *De Consolatione Philosophiæ* of Boethius; *De Unitate Ecclesiæ; Contra Sectam Flagellatorum; De Probatione Spirituum.* The *De Imitatione Christi* has been ascribed to G., but is the work of Thomas à Kempis. See Schmidt's *Essai sur G.* (Strasb. 1839), and Thomassy's *Jean G.* (Par. 1843).

Ger'stäcker, Friedrich, a German author, born at Hamburg, May 16, 1816. He emigrated to America in 1837, and after a chequered life as a sailor, hunter, trapper, and woodcutter, returned to Germany in 1843, and published an account of his wanderings in 1844. He went round the world in 1849–52; travelled across S. America in 1860–61; journeyed in Africa with Duke Ernst of Gotha in 1862; visited Central America in 1863; and died at Brunswick, May 31, 1872. Among his works are *Die Flusspiraten des Mississippi* (3 vols. Leips. 1848); *Amerik. Wald- und Strombilder* (2 vols. Leips. 1849); *Reisen* (5 vols. Stutt. 1853–54); *Nach Amerika* (1855); *Neue Reisen* (1868); &c. His writings have won great popularity, and several of them have been translated into French and English. G.'s travels give entertaining accounts of his varied roving career, and graphic pictures of Transatlantic life and scenery. His fictions are fresh, exciting, and realistic.

Ger'und (Lat. *gero*, 'I carry on') is a part of the Latin verb which expresses a *state* or *action* in a general way. It is a verbal noun possessing the power of governing the same case as its verb. It is used only in the oblique cases, the nominative being supplied by the infinitive, thus—nom. *amare*, 'loving;' gen. *amandi*, 'of loving;' dat *amando*, 'to loving;' acc. *amandum*, 'loving;' abl. *amando*, 'with loving.' It has no plural.—The **Gerundive**, on the other hand, is a passive participle, denoting that something is *to be done*, and generally implying possibility, expediency, or necessity, as *amandus, a, um*, 'to be loved, deserving or requiring to be loved.'

Ger'vas, or **Gervao,** a Brazilian name for *Stachytarpha et Jamaicensis*, a shrubby aromatic plant belonging to the natural order *Verbenaceæ.* Its leaves have been extensively used for adulterating tea.

Ger'vase of Til'bury, an English chronicler of the 13th c., was born at Tillbury in Essex, studied in France and Germany, and won the favour of the Emperor Otho IV., who made him marshal of the kingdom of Arles, and to whom he dedicated his *Otia Imperialia.* G. died about 1218. He is said to have been a nephew of Henry II. of England. His chief work, *Otia Imperialia*, deals with the history of the world from the creation to the rule of the Norman kings in England. It is, according to Morley (*English Literature*, p. 71), 'full of learning borrowed without acknowledgment from Petrus Comestor;' but is interesting as a storehouse of popular legends belonging to England and the country round Arles. G. also wrote *Illustrationes Galfridi Monemuthensis*, and *De Origine Burgundiorum.* See Wright's *Biographia Brit. Liter.*, vol. ii.

Gervi'nus, Georg Gottfried, a very eminent German historian and literary critic, born at Darmstadt, 20th May 1805. Though designed for a mercantile life, the influence of Schlosser on him while a student at Heidelberg attached G. to the science of history. The merit of historical sketches published by G. in 1833 secured him a call to the University of Göttingen. He was one of the seven professors who were, in 1837, deposed and banished for their protest against the change in the Hanoverian constitution. In 1844 he was called to Heidelberg, and in 1847 founded the *Deutsche Zeitung* in the interests of constitutional freedom. He was a member of the Frankfurt National Assembly, but soon withdrew from all political activity in disgust at the course of events. He died at Heidelberg, 18th March 1871. G.'s most important writings are the great work known since its fourth edition as *Geschichte der Deutschen Dichtung* (1st ed. 1835–42; 5th ed. 1870); the *Grundzüge der Historik* (1837); *Shakespeare* (4 vols. 1849–52; 3d ed. 2 vols. 1862), the *Geschichte des 19ten Jahrhunderts* (8 vols. 1855–66). His *Hinterlassene Schriften* appeared in 1871. G. treated history not as a mere series of events, but as an organic growth; and in poetry he saw an outcome of the social and political conditions of the period which gave it birth. See the Lives of G. by Gosche (Leips. 1871) and by Lehmann (1871).

Gese'nius, Friedrich Heinrich Wilhelm, an Orientalist and an exegete whose labours form an era in the history of Semitic philology, was born at Nordhausen, 3d February 1785. In 1811 he became a professor at Halle, where he taught till his death, 23d October 1842. G.'s linguistic-critical method of interpreting the Old Testament produced in his hands rationalistic results, which excited much opposition from the orthodox party. Of his works, the best are the universally-known lexicon, the *Hebr. und Chaldäisches Handwörterbuch* (1810–12, 6th ed. 1863; Latin translation, 1846; English translation by Robinson and by Tregelles); *Hebr. Elementarbuch*, consisting of a grammar (1813; 18th ed. by Rödiger, 1857; also familiar to all English students as translated by Davies), and a reading-book; a more elaborate grammar in 1817; and the *Thesaurus Philologico-Criticus Linguæ Hebr. et Chald.* (completed by Rödiger, 1829–58); besides a commentary on Isaiah, a history of the Hebrew languages, and treatises on Samaritan theology and Phœnician inscriptions.

Ges'ner, Johann Matthias, a celebrated German humanist, born at Roth, near Nürnberg, 9th April 1691. After completing his studies at Jena, he became in 1715 con-rector and librarian at Weimar, in 1728 rector of the gymnasium at Ansbach, in 1730 rector of St. Thomas School, Leipsic, in 1734 Professor of Rhetoric, and in 1735 librarian in the University of Göttingen. He died 3d August 1761. G. laboured with intelligence and zeal for the improvement of classical studies, and formed a wider and higher idea of culture than was customary among pedagogues. His chief works are his editions of the *Scriptores de Re Rustica*, of Quintilian, Claudian, Pliny the Younger, and Horace; his *Primæ Lineæ Isagoges in Eruditionem Universam* (new ed. Leips. 1784); *Novus Linguæ et Eruditionis Romanæ Thesaurus* (4 vols. Leips. 1749); *Opuscula Varii Argumenti* (8 vols. Bresl. 1743–45); and *Thesaurus Epistolarum Gesneri* (Halle, 1768).

Gesnera'ceæ, a natural order of Corollifloral plants embracing about 80 genera and 300 species. They are principally herbs, rarely shrubs, found in various quarters of the globe, but chiefly in the warmer regions of America. Several species of *Gloxinia, Achimenes*, and *Gesneria* are cultivated in hothouses for their showy flowers and foliage.

Gess'ler, Albrecht, in the tradition of Tell (q. v.), figures as the governor set over the Forest Cantons of Schwyz, Unterwalden, and Uri by Albrecht I. of Austria in 1300. He is painted as a cruel oppressor who was shot by the Swiss hero in a defile near the castle of Küssnacht in 1307. But there is no governor of that name mentioned in the still extant charters of the 14th c. relating to Küssnacht, and the story is therefore either not historical at all, or has lost its strict historical outline during its oral preservation as a legend. See *Tell und G. in Sage und Geschichte*, by E. L. Rochholz (Lond. 1876).

Gess'ner (Lat. *Gesnerius*), **Konrad,** a Swiss polyhistor and naturalist, was born at Zurich, March 26, 1516. After studying at Strasburg and Paris, he became schoolmaster in his native town. Resolving to study medicine, he resigned his post, went to Basel, and later to Lausanne, where he was appointed Professor of Greek. After three years G. proceeded to Montpellier to complete his medical studies, returning ultimately to Basel, where he received his doctor's degree in 1541. He then began practice at Zürich, where he was soon elected Professor of Philosophy, a post which he occupied till his death, December 13, 1565. G. was a most prolific writer on medical, zoological, historical, and philological subjects. His greatest works are *Bibliotheca Universalis* (1545–49), and *Historia Animalium* (5 vols. 1551–87), which was planned in six volumes but never completed, the fifth volume being published posthumously. See Hanhart, *Biographie G.'s* (Winterth. 1824).

Gessner, Salomon, a Swiss painter and poet, was born at Zürich, April 1, 1730. After an imperfect education, he was apprenticed by his father to a bookseller at Berlin, but soon deserted trade, and sought to gain a subsistence as a landscape painter. At Hamburg he formed a friendship with Hagedorn, and returning from that town to his native place, devoted himself to the cultivation of poetry. In 1754 he produced a work in

verse called *Daphnis*, and some time after, *Inkle and Yarico*, *Idylls*, and the *Death of Abel*. This last is a kind of prose epic, which gained a celebrity beyond its deserts. In 1762 G. published four volumes of *Poems*, and after that period gave much attention to engraving. In 1772 he published a collected edition of his works, and on March 2, 1788, died at Zürich. G.'s Life has been written by Hottinger (Zür. 1796).—His son, **Konrad G.** (born 1764, died 1826), distinguished himself as a landscape-painter.

Ges'ta Romano'rum (Lat. 'the deeds of the Romans'), a collection of stories, mostly intended to convey moral lessons, highly popular in the middle ages, the authors of which in their mediæval form are unknown. Warton wrongly ascribes them to Petrus Berchorius, a Benedictine prior who lived at Paris in the 14th c.; their real compiler seems to have been an English or German monk named Elinandus. They are partly tales of Greece and Rome, especially of the Roman Empire, partly Eastern apologues, and partly chivalrous and saintly legends of the middle ages; but all these varying times and themes are harmonised by a naïve, charming anachronism—Romans and Greeks being represented as chivalrous knights, and placed amid Gothic surroundings. A moral is added to each tale, and the whole work is marked by a strange, delightful, and almost infantile simplicity of manner and incident. Ovid, Valerius Maximus, Aulus Gellius, Pliny, Seneca, Boethius, are referred to for several of the classical tales, and many of the Oriental fictions are taken from the Arabian stories in the *De Clericali Disciplina* of Petrus Alphonsus and the romance of *Baarlam and Josaphat* (q. v.). English poets have been largely indebted to the G. R. Chaucer and Gower each borrowed two of their stories from them; they contain the plot of Shakespeare's *Pericles*, and the stories of the caskets, the bond of the pound of flesh, and Portia's judgment, which reappear in the *Merchant of Venice*. We also find in the G. R. the basis of the spectral episode in *Marmion*, the magic mirror which occurs in the *Faerie Queene* and in the pseudo-legend of Surrey and Geraldine, the story of Parnell's *Hermit*, and an early version of the *Three Black Crows*. The G. R. have likewise supplied many themes to the Italian poets and novelists, *e.g.*, the story of the nobleman who made his wife drink nightly from the skull of her slain adulterer, which occurs in various Italian poems, in a tragedy by Rucellai, in the thirty-second tale of the Queen of Navarre, and in a ballad by Stolberg. It was perhaps from the G. R. that the Italian writers caught their love for tales of magic and enchantment. The German fabulists also borrowed freely from the G. R. These tales were known in England before the end of the 13th c., and were widely popular till the 16th c.—their fame waning at the Reformation. The first edition of the original Latin work was issued at Köln in 1472, the first Dutch translation appeared in 1481, and the first German at Augsburg in 1498. See the Rev. C. Swan's *G. R. translated from the Latin* (Lond. 1824, new ed. revised by Wynnard Hooper, 1877).

Gesta'tion (Lat. *gestatio*, from *gesto*, 'I carry on'), the term applied collectively to the series of actions and processes involved in the development and nutrition of the embryo or young animal within the *uterus* or *womb*. The name is also used to indicate the *period* of intra-uterine development. G. follows the *impregnation* of the ovum. In cases of *abnormal* G., this process may take place *without* the uterus, when the process is known as that of *extra-uterine* G. The embryo may thus be developed within the *Fallopian tube* or *oviduct*, such instances being named cases of *tubal pregnancy;* or sometimes the process may be more or less intimately related to the abdominal cavity itself. The period of human G. is usually estimated at forty weeks—nine months or 280 days; but these limits may in many instances be exceeded, and cases of G. lasting for a less period may frequently be met with. Occasionally grave points of law have had to be settled by the determination of the length of the period of G. in particular cases. As a general rule, where many young are produced at a birth, the period of G. is short. Its duration varies greatly in different animals. The elephant goes with young for twenty or twenty-one months, producing but a single young one at a birth. The period of G. in the giraffe is about fourteen months, of the camel twelve months, of the horse eleven months; that of the cow is nine months, and that of most of the deer eight months. The sheep carries her young for five, and the pig for four months. The lion appears to go with young for about three or three and a half months, and the bear for about six months, whilst the dog's period of G. is sixty-three days, and that of the cat fifty-five or fifty-six days. See also FŒTUS, PARTURITION, &c.

Ge'tæ. See DACIA.

Gethsem'ane (Aram. 'oil-press') was a place between the Brook Kedron and the Mount of Olives, about half a mile from the E. wall of Jerusalem, where was a garden to which our Lord retired on the night of his betrayal, where his agony took place, and where he was apprehended by the emissaries of the Jews, led by Judas (Matt. xxvi. 30–56; Mark xiv. 26–50; Luke xxii. 39–54; John xviii. 1-12). See Stanley's *Sinai and Palestine* (new ed. Lond. 1871).

Gett'ysburg, a town on the S. border of Pennsylvania, U.S., 28 miles W. by S. of York by railway. It is the seat of the state college, and has some carriage-making and granite quarrying. Pop. (1870) 3074. In and around the town was fought the fierce battle of G., between the army of the Union under General Meade and the Confederates under General Lee, which lasted for three days, ending in favour of the former on 3d July 1863. Although it had an important bearing on the course of the war, it was but a desperate 'soldiers' battle.' The killed and wounded on the side of the victors were 16,500; on the side of the South 18,000. See Bates' *Battle of G.* (Phil. 1875).

Ge'um, a genus of perennial plants belonging to the natural order *Rosaceæ* (q. v.). There are a number of species found in the temperate parts of the northern hemisphere. Only two are indigenous to Britain, viz., *G. urbanum*, the common or wood avens, and *G. rivale*, the water avens. The root of the former is aromatic, and possesses astringent properties. The root of *G. Canadense*, called chocolate or blood root in America, has been used as a tonic. *G. coccineum* is cultivated in gardens for its handsome scarlet flowers.

Gey'sers are a class of hot springs characterised by periodic eruptions. The name is of Icelandic origin (*geysa*, 'to be forced out with violence'), and is strikingly descriptive of these springs, which are very numerous in the volcanic regions in the S.W. of Iceland. The most remarkable in that island are the Great Geyser and Strokkr (Eng. 'churn'), about 70 miles E. of Reikiavik. The former consists of a cylindrical tube, about 12 feet wide and 80 feet deep, which opens into a bowl shaped trough, 6 or 7 feet deep, with an average diameter of 60 feet, and situated on the summit of a circular mound from 26 to 32 feet high and 210 feet in diameter. The cylinder and bowl are always filled with water (except immediately after an eruption), the temperature of which varies on the upper surface from 76° to 89° C., but attains in the tube at a depth of 60 or 70 feet a point as much as 20° above the boiling-point. Bunsen in 1846 observed a temperature of 127° C. (261° F.) a few minutes before an eruption. The possibility of water remaining water at such a high temperature is due no doubt to the increased pressure at those depths, and also to the comparative freedom of the water from air. Every few hours the Great Geyser becomes tumultuous, a condition which is accompanied by underground rumblings; but it is only at intervals of a day or so that this tumult becomes so intensified as to produce the characteristic feature of geyser action, the forcible ejection of volumes of steaming liquid to a height of 60 or 80 feet. After some fifteen minutes' activity the eruption ceases; and the tube and basin, left almost empty, gradually fill with clear sea-green water, which then trickles slowly over the margin and down the slope, where, through evaporation, it deposits the silica which is the main constituent in the formation of the mound and the smooth sides of the basin. The Strokkr, which lies 100 paces from the Great Geyser, presents a curious funnel-shaped tube, and its eruptions take place every two or three days. These natural wonders, long supposed to be peculiar to Iceland, have more recently been discovered in New Zealand and the United States. The region to the N. of Lake Taupo in the province of Auckland abounds in hot springs, fumaroles, solfataras, &c. In many places the country is beautifully terraced by siliceous deposits, and whole lakes—Rotamahana for example—are maintained at an average temperature of from 70° to 80° C. At the N.E. end of this lake

is the Tetarata spring, which presents usually the appearance of an immense cauldron, 80 feet long and 60 wide, and filled with clear, ever-boiling water, and which is probably a geyser with long intervals of quiet. In the vicinity of Lake Rotorna are seven or eight periodic G., the principal one being the Waikite near the native settlement of Whakarewarewa. It sometimes spouts to a height of 30 or 40 feet. See Hochstetter's *New Zealand* (1867). The Yellowstone National Park in the N.W. of Wyoming Territory, U.S., abounds in G., hot springs, and sulphur springs of every description. One of the most remarkable of the G. is Old Faithful, which spouts on an average once an hour, each eruption lasting not quite five minutes, and the column of water attaining a height of 120 or 130 feet. The Bee-Hive is surmounted by a dome-shaped chimney through which the water and steam forcibly escape, rising to a great height in the form of a fine spray and ultimately evaporating in the air. The Grand Geyser has magnificent eruptions, the column sometimes attaining a height of over 200 feet. The Grotto, the Giant, and the Giantess are also first-rate spouters, quite throwing into the shade their Icelandic brethren. For full information regarding the G. and hot springs of this curious region see Hayden's *Sixth Annual Report of the United States Geological Survey* (1873), and Jones' *Report upon the Reconnaissance of North-Western Wyoming, including Yellowstone National Park* (1875).

The first theory of geyser action was stated by Sir George Mackenzie, who visited Iceland in 1810. He explained the ejection of water as produced by the expansion of steam which had accumulated under constantly increasing pressure in an underground cavern connected by a duct with the geyser tube. Bunsen in 1846 showed that a simple tube was quite sufficient to account for any eruption; and a veritable geyser may be exhibited on a small scale by heating a tube filled with water in two places—at the bottom and about half-way up. In the geyser tube, by lateral heating, the body of water at a certain depth is raised to its boiling-point, expands, and pushes the superincumbent column of water up. This necessitates an overflow of water at the margins of the basin, therefore a diminished pressure and a consequent lowering of the boiling-point of the water in the tube. Any portion of the column which was formerly at its boiling-point will be now suddenly converted into steam, whose expansive energy will be evidenced in the sudden ejection of the superimposed water. Such is a brief outline of Bunsen's theory, which does not, however, in itself give a full explanation of several curious points recently brought to light in the Yellowstone region regarding a physical connection between contiguous G. The study of these sympathetic fountains will no doubt throw much light on the nature of their workings. Besides the works already cited see Mackenzie's *Travels in Iceland* (1810), Kloden's *Erdkunde* (1873), and Lyell's *Principles of Geology* (10th ed. 1866).

Gfrö'rer, August Friedrich, a German historian, was born at Calw in the Black Forest, 5th March 1803, and was educated for the Protestant ministry. In 1830 he forsook theology for literature. Even his earlier works, *Philo* (Stuttg. 1831), *Geschichte des Urchristenthums* (3 vols. Stuttg. 1838), and *Gustav Adolf* (2 vols. Stuttg. 1835–37, 4th ed. 1863), showed a leaning to Catholicism, and in his *Allgemeine Kirchengeschichte* (4 vols. Stuttg. 1841–46) he professed himself a Catholic. In 1846 he became professor in the Catholic University of Freiburg, and was active as a keen Ultramontane till his death, 10th July 1861. The chief of his later works are *Untersuchung über die Decretalen des falschen Isidorus* (Freib. 1848), *Geschichte der Ost- und Westfränk. Karolinger* (2 vols. Freib. 1858), *Papst Gregor VII.* (7 vols. Schaff. 1859–64), *Gesch. des 18ten Jahrhunderts* (3 vols. Schaff. 1862–63).

Gha'ra, the name given to the Sutlej river in N.W. India, for a distance of about 300 miles between the confluence of the Beas and its final junction with the Chenab.

Ghas'el, or **Ghazel** (Arab. 'love-poem'), a form of lyrical poetry among the Turks and Persians which has been compared to the Western sonnet. It consists of not less than fifteen, and not more than seventeen strophes of two lines each, and the last strophe invariably contains the real or assumed name (*tachallus*) of the author. The finest specimens are by Hafiz (q. v.), many of whose ghasels are mystical and philosophical under a bacchanalian guise.

Ghaut (*ghat*), the Indian name for a passage or gateway, usually applied to the structures erected on the sides of rivers, tanks, or lakes, to facilitate the access of bathers. These consist of wide masonry steps, sometimes protected above with walls and porticoes. They are most numerous and most highly ornamented on the Ganges, especially at Benares and other sacred spots. See Fergusson's *Hist. of Ind. Architect.* (Lond. 1876).

Ghauts, Western and Eastern. The name given by Europeans to the two parallel hill-ranges which fringe either coast of the Indian peninsula. The W. G., which alone can be called mountains, start from the central plateau, and first stretch W. along the left bank of the Tapti, where they are sometimes called the N. G.; presently they turn due S. and run down almost continuously to Cape Comorin, at a distance from the Indian Ocean which nowhere exceeds 70 miles. The total length may be 1000 miles, the average height about 4000 feet, the highest point about 7000 feet. They form an absolute watershed, being pierced by no rivers, and sending all their water to the E. They cut off the clouds from the Indian Ocean, and their W. slope has an annual rainfall of more than 100 inches. They are twice crossed by the Great Indian Peninsula Railway, near Nasik and near Poonah; and also by the Madras Railway, at the gap of Palghaut, which is 16 miles broad, and practically divides the W. G. into two distinct portions. The E. G. are altogether less important. They commence in Orissa, S. of the Mahanadi river, and run S.W. at a considerable distance from the Bay of Bengal, and in a very broken chain, till they cross the point of the peninsula and join the W. G. N. of the gap of Palghaut. Their average height is not more than 1500 feet, and they are penetrated by the valleys of the Godavari and Kistna. The Neilgherries form the junction between the two ranges, and contain Dodabetta Mountain (8640 feet), but not even here has snow been known to fall.

Ghazi, an Arabic word signifying 'champion or hero,' especially assumed by those Mohammedans who have slain infidels in battle, in the form of *ghazi-ûd-din*, 'champion of the faith.'

Ghazipore' (*Ghazipur*), the chief town of the district of the same name in the N.W. Province, British India, on the left bank of the Ganges, 431 miles N.W. of Calcutta and 46 N.E. of Benares. Pop. (1871) 38,853. It has a ruined palace, now a custom-house, said to have been built by Mîr Cossim, Nawab of Bengal, and a stone obelisk in memory of Lord Cornwallis, who died here in 1805. The military cantonments lie to the S.W. G. is celebrated for its rose-water, and also for its horse races.—G. *district* is intersected by the Ganges and many minor streams, and bordered by the Gogra. Area, 2168 sq. miles; pop. (1872) 1,345,570. The spring crops are maize, rice, pulses, and oil-seeds; the summer crops, wheat, barley, opium, and sugar-cane, which last is of especially fine quality. The exports towards Bengal are sugar, saltpetre, cereals, and oil-seeds, from the river marts of G., Balia G., and Moniar; the imports are rice and piece goods. The latter come by the East Indian Railway, which traverses the S. of the district.

Ghazzali-al-Abou-Ibn-Hamid-Mohammed, an Arabian philosopher, born at Tus, Persia, in 1058, son of a merchant in cotton (*ghazal*), whence his surname G. After studying at Djorshan and Nishapur, he was made Professor of Theology at Bagdad, and after holding various offices as a teacher, died at Tus in 1111. G. is one of the foremost Arabian authors, and has been surnamed *Zain Eddin* ('glory of the law'), though he does not always adhere to strict orthodoxy. His chief work is the *Ihjâ Olûm ad-Din* ('Restoration of Religious Sciences'), of which it has been said 'If all the books of Islam were lost and we had only this one left, we should not miss the others.' Among his other writings are *Kitabunnahali-Filâsafa* ('On the Opinions of Philosophers'), *Tahâfat Al-Filâsafa*) ('The Destruction of Philosophers'), &c., and various moral and philosophical treatises. Most of his works are lost. See Schmolders's *Essai sur les Écoles Philosophiques chez les Arabes, et notamment sur la Doctrine d'Al-Gazzan* (Par. 1842).

Ghee (*ghî*), the name given to the boiled butter which is in universal use among the natives of India in cooking and for sweetmeats. The best is prepared from the milk of the buffalo, and where those animals are kept G. forms an important article of manufacture and of local trade.

Gheel, or **Geel,** a town in the province of Antwerp, Belgium, in the Campine, 25 miles W. of Antwerp. It has a shrine of St. Dymphnea, to which the insane have resorted for cure since the 7th c. This class has settled in large numbers at G., partly in the hope of miraculous cure, partly because of the kind treatment they receive from the citizens and the neighbouring farmers. In recent years a medical staff has been organised, and cottage asylums have been established under the control of Government. Pop. 11,614. See Duval's *G., ou une Colonie d'Aliénés vivant en Famille et en Liberté* (Par. 1860).

Ghent (Flem. *Gend*, Ger. *Gent*, Fr. *Gand*), the capital of East Flanders, Belgium, at the confluence of the Lys, Scheldt, Lieve, and Moère, 35 miles W.N.W. of Brussels by railway. It is a quaint old town, rising here and there in ornate dusky brick piles, and enclosed by walls eight miles in circuit, girt with pleasant gardens and promenades. Separated into some twenty-six islands by various canals and branches of the rivers, it is bound together by means of about 300 bridges, of which forty-two are of stone. The Great Canal, connected with the Scheldt, enables vessels drawing 18 feet of water to enter the docks of G., which can accommodate some 400 vessels. G. has a cathedral of St. Bavo, with a grand interior, a crypt of date 941, a beautiful choir and chapel of 1228, and many fine pictures, including four of the original thirteen famous *Agnus* studies by the brothers Eyck. Other notable buildings are the Gothic church of St. Michael of 1480; the church of St. Peter, rebuilt in 1720, and containing rare pictures; part of an old abbey, converted into barracks for 4000 men; a new (1830) citadel on the Blandinus Mount, the sole height in the district; a university with 450 students since 1816; the Beguin establishment, with 130 houses, 18 convents, 2 chapels, and 700 nuns; the townhouse (begun 1200), with a richly-carved façade; a palace of justice (1844), designed by Roelandt; an art academy; the best botanical garden in Belgium; a library of 100,000 volumes and 700 MSS.; a fine theatre (1848); and a large casino (1836) for concerts. From the centre of G. rises the old Belfroot or Beffroi (1183-1339), a square watch-tower 387 feet high, with an iron peak (renewed in 1854), a peal of forty-four bells, and a gilt dragon-vane, brought by Baldwin IX. from Constantinople in 1204. In the historic and picturesque Vrydag Markt a statue of Jakob van Artevelde was raised in 1863. G. has 29 cotton factories, with 480,000 spindles and 4800 hands, several large flax-spinning factories, extensive cotton-print and dye works, sugar refineries, &c., and a large floricultural trade. Sluices 15 miles to the N. can lay the whole district under water. Pop. (1873) 116,693. G. is first mentioned in the 7th c. A fortress was built here in 868 by Baldwin Bras-de-Fer as a defence against the Norsemen; in the 13th c. it became the chief seat of the Counts of Flanders, and rose in the 15th to be the richest and most populous city in Europe. Under Jakob van Artevelde (q. v.) G., with an army of 50,000 men, resisted Louis of Flanders. It struggled long against the Dukes of Burgundy, but at last was obliged to yield. Under Karl V. its splendour began to fade. By the *Pacification of G.*, Holland, Zeeland, and the S. provinces of the Netherlands joined against Spain in 1576, and took an active part in the War of Independence, until it succumbed under the cruelties of the Duke of Parma. When the Netherlands was overrun by the French in 1792 G. became capital of the department of the Scheldt, and so remained till the overthrow of Napoleon. By the *Treaty of G.* peace was concluded between England and the United States, December 24, 1814.

Gherardes'ca, a Tuscan family which played a large part during the middle ages in the history of Pisa, and supported the Ghibelline cause. The most notable of the house was Count Ugolino, whose story is immortalised in the 33d canto of Dante's *Inferno*. Banished for plotting to make himself tyrant of Pisa, he was restored by the aid of Florence and Pisa, and in 1284 betrayed the Pisan forces to the Genoese in the battle of La Meloria. Through intrigues with the Guelphic enemies of the republic, he maintained a despotism over the Pisans, governing with the darkest treachery and cruelty, until in 1288 a revolt broke out, led by Archbishop Ruggieri, and G. was seized and cast, along with his two sons and two grandsons, into the dungeon of a tower, where they perished of hunger. The tower was afterwards known as the Tower of Hunger (*Torre della Fame*). Dante places G. in the icy lake in hell. The family again rose to power in the first half of the 14th c. See Sismondi's *Histoire des Républiques Italiennes*, vol. iv.

Gher'iah, the name of two places celebrated in Indian military history. One of these, also called Viziadrug, 170 miles S. of Bombay on the sea-coast, was captured from the Mahrattas in 1755 by a British fleet and army under Admiral Watson and Colonel Clive. At another G., near Mûrshedabad, on the Ganges, 140 miles N. of Calcutta, Major Adams, after a hard-fought battle, defeated the Nawab Mîr Cossim in 1763, and finally established the pre-eminence of the East India Company in Bengal.

Ghib'ellines. See GUELPHS AND GHIBELLINES.

Ghiber'ti, Loren'zo, sculptor and designer, was born at Florence in 1378, and in 1401 joined in a competition to which all sculptors were invited by the guild of merchants of Florence, and the object of which was to produce a design in basso-relievo for a gate to the baptistery of San Giovanni. G.'s design was allowed to be the best even by the other competitors, among whom were Brunelleschi and Donatello. In carrying out his design—the 'Sacrifice of Isaac'—G. was occupied twenty years, after which his townsmen commissioned him to design and carve a companion gate for the same building. The subject of this splendid work was also biblical. These two works contain the best sculpture of the 15th c., and to this day they remain unrivalled for the highest qualities of art. Michael Angelo said they were worthy to adorn the gateway to paradise. He died at Florence in 1455. Twelve beautiful etchings of these gates were published by Feodor Ivanovitch in 1798. See Hagen's *Chronik seiner Vaterstadt vom Florentiner Lorenz G.* (Leips. 2 vols. 1833; 2d ed. 1861).

Ghi'ka Family, a noble house of Albanian origin, many of whose members have been hospodars of Moldavia and Wallachia. —**Gregor G.**, an Albanian peasant, founded the house in the 17th c. He entered the service of the Governor of Moldavia, went to Constantinople, and by intriguing obtained the hospodarship of Wallachia in 1657. He was succeeded by his son **Gregor II.**, who was poisoned at Constantinople about 1680. The most famous of the later members of the family are—**Alexander G.**, born in 1795, and hospodar of Wallachia from 1832 to 1825, and from 1834 to 1842. He did much to better the condition of his subjects, and pursued a liberal and wise policy until the Sultan stripped him of his power. He then lived at Dresden and Vienna until 1853, when he returned to Wallachia, of which he was made *caimacum* in 1856. He died at Torre-del-Monte, near Naples, in 1862.—**Gregor X.**, born in 1803, was made hospodar of Moldavia in 1849. His government was marked by anti-Russian leanings, and by zealous efforts to improve education, establish order, remove abuses, and forward the union of the Danubian principalities. He freed the serfs, removed the censorship of the press, and carried many liberal measures. On retiring from office in 1856, G. removed to France. He died in July 1857. For Helena G., see DORA D'ISTRIA.

Ghilan' (Arab. *ghil*, 'mud'), a province in the N.W. of Persia, bounded N. by the Caspian, E. by Mazandaran, S. by Khamseh, and W. by Azer'bijan. Area, 4673 sq. miles; estimated pop. 100,000. It is low-lying and jungle-clad towards the Caspian, but to the S. is traversed by the lofty Bagra Koh or Talish Mountains and the Elbruz range, both densely wooded and covered with snow in winter. The wild animals include the tiger, panther, boar, jackal, vaspen, and deer, while the marshy coast and reedy islands are swarming with wild-fowl. The climate is damp and malarious, especially from June to September; much rheumatism, small-pox, and cutaneous disease prevails. The natives, who are handsome though often sickly, are chiefly engaged in the cultivation of silk (£75,000 worth yearly), oranges, lemons, and limes, and in rearing ponies, humped cattle, and fat-tailed sheep. They speak a rapid dialect (*Ghilaik*) of Persian, and are bigoted Mohammedans. Resht and Lahijan are the only considerable towns. G. was ceded to Peter the Great in 1724 for aid granted to drive out the Afghans. The Russians, however, were forced to retire by Nadir Shah in 1736, and since then have always claimed the territory.

Ghirlanda'jo, properly **Domenico Corradi,** one of the greatest painters of his time, was born at Florence in 1451, and was instructed in goldsmith's work by his father, who, as the

designer of a garland (Ital. *ghirlanda*) or head-dress much esteemed by the Florentine ladies, was named Il Ghirlandajo. He afterwards devoted himself to painting, and acquired the highest fame as a painter and designer in mosaic. He died in 1495. To his school in Florence many of the greatest Italian painters owe their training. His chief work, the 'Massacre of the Innocents,' together with other great frescoes, is in the choir of Santa Maria Novella, Florence. He painted portraits, wonderful in their fidelity and freshness, of Lorenzo de Medici and other famous Florentines. His brothers Benedetto and Davidde, and his son Rodolfo G. (born 1485, died 1560), were also celebrated painters. G. is supposed to have discovered the laws of aerial perspective.

Ghiz'eh, or **Gizeh** (Copt. *Tpersioi*), the capital of a province of the same name in Lower Egypt, on the left bank of the Nile, opposite ancient Cairo. It was formerly a flourishing fortified place of the Mamlukes, but is now a miserable village. There are still here ovens for egg-hatching, and in the vicinity are three of the largest Pyramids (q. v.) and the great Sphinx.

Ghiz'ni. See GHUZNI.

Ghost-Moth (*Hepialus humuli*), so called from the silvery-white colour on the upper parts of the male, and from the suddenness with which it disappears from sight. The under parts are brown in both sexes. The male insects have the habit of hovering over the female at twilight as the latter lie concealed in the grass. The rapid and spectral-like disappearance of the moth when alarmed is due to the insect's fluttering to the ground, and there concealing itself from view by turning the lower and brown side of its body uppermost. The larvæ commit ravages in hop-fields, and also live on nettles, &c.

Ghümuldji'na, or **Komuldsi'na**, a town in the vilayet of Adrianople, European Turkey, on the Karaji, near the S. base of the Karlyk Bagh, 80 miles S.W. of Adrianople and N.E. of Lagos Bay. It has a citadel and a trade in silks, opium, and perfumes. Pop. 9000.

Ghur, a small town in Afghanistan, has given its name to the Ghurian dynasty, which succeeded the Ghiznevides in Hindustan in 1186 A.D., but only maintained itself for a few generations. It fixed the Mohammedan power in India more permanently than its predecessor, but was itself overwhelmed by Genghis Khan.

Ghuz'ni, or **Ghizni** (*Ghazni*), an ancient town and fortress of Afghanistan, 7726 feet above the sea, 85 miles S.W. of Cabul. A still older G., first heard of in the 10th c., was the capital of the great conqueror Mahmud of G., and was taken and destroyed by Allah-ud-dîn of Ghur in 1151. The only old building remaining is the tomb of Mahmud, before which used to stand the supposed sandal-wood gates of Somnauth. The existing G., 3 miles to the S.W., on the G. river, is still strongly fortified, and there is some trade. In 1839 it was stormed by the British under Sir J. Keane, and in 1842 evacuated and again retaken by General Nott. On this last occasion the Somnauth gates, as they were called, were carried off to Agra. Pop. 8000. G. has given name to the *Ghiznevide dynasty*, which dominated over Central Asia from 961 to 1186. The founder was Abastakin, an adventurer from Bokhara; his grandson Mahmud ravaged Hindustan five times, and extended his empire from the Tigris to the Ganges. The last king, Khusrû Melek, was killed at Lahore by the King of Ghur, who had previously expelled the dynasty from G.

Gianibell'i, Federigo, an architect and military engineer, was born about 1530 at Mantua. After failing to obtain the patronage of Philip II. of Spain, he removed to England, and offered his services to Queen Elizabeth, by whom he was sent in 1585 to relieve Antwerp, then closely besieged by the Duke of Parma, Spain's generalissimo. After a little he succeeded in inventing an infernal machine which annihilated the huge bridge built by the Spaniards across the Scheldt, and which completely barred the entrance to the city. But the internal discord of the citizens hindered them from reaping any benefit from his ingenuity, and G. returned to England. The fire-ships which wrought such confusion in the fleet of the Armada were also the fruits of his inventive genius. After this no more is heard of him, but he presumably died in London.

Gianno'ne, Pietro, an Italian historian and jurist, was born at Ischitella in Naples, 7th May 1676. After a distinguished career at the Neapolitan bar, he withdrew from the practice of his profession, and assiduously devoted himself to historical literature. The fruits of his studies appeared in 1723, when he published his great work, *Storia Civile del Regno di Napoli*, in 4 vols. (new ed. Milan, 5 vols. 1845–47). It is characterised by wide and various learning, critical insight, and a philosophic spirit. In a thoroughly modern fashion G. illustrates the political, social, and religious influence of the successive civilisations that established themselves in Southern Italy. His ecclesiastical opinions excited the hostility of the clergy, and G. was forced to abandon his country and seek a refuge in Vienna. After some years he went to Venice, and thence to Modena, Milan, Turin, and Geneva, where he wrote a fierce diatribe against the Papacy, entitled *Il Triregno, Ossia de Regno, del Cielo, della Terra e del Papa*, and seems to have even adopted the doctrines of Calvin. Induced by false representations to re-enter Sardinia, he was arrested and imprisoned at Turin, where he died, 7th March 1748. Other works of G. were posthumously published. There is some evidence to support the opinion that, in spite of his high qualities, G. was proud, dictatorial, and intolerant in the expression of his sentiments, and had a way of making enemies rather than friends. See Panzini's *Vita di P. G.*

Gi'ants and Dwarfs. A giant (Gr. *gigas*, 'a giant,' Fr. *géant*, from *gĕgenēs*, 'earth-born; '*gē*, 'the earth,' and *gignomai*,' I am born'), is a man greatly exceeding the average of his species in height and bulk, while a dwarf (Goth. *dvairg*, which Grimm thinks may be identified with the Gr. *theurgos*, 'a divine worker') is an individual of diminutive stature. The belief, almost universal until the beginning of the 19th c., that giants of colossal size had formerly existed is now exploded, the huge bones which were thought to have belonged to enormous men having been proved to be the remains of mammoths and other great quadrupeds. Two races of giants are mentioned in Scripture—the Nephilim, who lived before the Flood, and the Rephaim, who dwelt in Palestine in the days of Joshua. Some, however, are of opinion that Nephilim merely signifies bearded, or cruel, or violent men. Individual giants, such as Og, King of Bashan, and Goliath, are also spoken of in Scripture. There are several dubious references to giants in ancient Greek and Latin authors. Thus Arrian tells us that Porus, King of India, was 5 cubits high, and Pliny speaks of an Arab of 9 feet 9 inches high who lived in the reign of Claudius. Men have been known to attain a height of between 8 and 9 feet, and even this stature may have been exceeded. In the museum of Trinity College, Dublin, there is a skeleton, that of O'Brien, 8 feet 6 inches high, and the museum of the College of Surgeons, England, contains a skeleton of 8 feet 2 inches. Bishop Berkeley is said to have tried to rear a giant on hygienic principles. The orphan named Magrath whom he selected for the experiment died at the age of twenty when he was 7 feet 8 inches high. Dwarfs were common among the Romans who called them *nani* and *nanæ*, and occasionally sought to check the growth of the children of slaves by means of bandages. The most famous dwarf of ancient times was Philetas of Cos, who was one of the best poets of his time, and tutor to Ptolemy Philadelphus, and of whom the story runs that he had to carry weights to escape being blown away. In the middle ages dwarfs were generally kept at the courts of princes and nobles, a custom which did not become extinct until the end of the 18th c. Among the smallest dwarfs of whom we have thoroughly reliable information are Bebé, the dwarf of Stanislaus, King of Poland, who was under 3 feet when he died, at the age of twenty-three, and Count Joseph Borowlaski, who was 2 feet 4 inches high at the age of twenty, and 3 feet 3 inches high at the age of thirty. He died aged ninety-eight, and had a brother 3 feet 6 inches high. As compared with dwarfs, giants are for the most part much shorter lived, dwarfs often attaining a very old age; and much feebler in mind, dwarfs being generally lively and keen witted; giants are also often malformed or badly proportioned, while dwarfs have often great symmetry of shape. The belief that races of dwarfs lived in certain parts of the world was once widely diffused, and is now seen to have a certain basis of truth. The Greeks, and among others Herodotus and Aristotle, held that a race of pygmies lived on the Upper Nile, and the Portuguese writers of the 17th c. speak of a dwarfish race in the in-

terior of Africa named Bakka-Bakka. These beliefs seem to have been founded on facts. Dr. Schweinfurth (*Heart of Africa*, 1873), when travelling on the Upper Nile, saw several specimens of a dwarfish people named Akka, who inhabit an unknown district between lat. 2° and 1° N. Their average height, he says, was 4 feet 10 inches, and they were distinguished by a redder or brighter complexion from the other native races. His description substantially agrees with Du Chaillu's account of the Obongo, a wandering race whom he met in the Ashango territory, and whose average height he estimates at 4 feet 7 inches. Natives of stunted growth are reported to inhabit parts of E. Tropical Africa, as the Doko, who dwell on the Upper Juba, and who are said to be about the height of boys ten years old. Schweinfurth considers it almost certain that these people of small stature, who may have given rise to the Greek tales of pygmies, are the 'scattered remains of an aboriginal population now becoming extinct.' There are very conflicting accounts as to a race of dwarfs said to inhabit Madagascar; it seems probable that an under-sized people dwells in the interior of the island. Another people considerably shorter than the average are the Esquimaux (q. v.). Until recently it was credited that the Patagonians were of gigantic stature, but it is now proved that, though generally tall, they are by no means giants.

Giants and Dwarfs in Mythology.—There are various legends of the *Gigantes* or giants in Greek mythology. Homer describes them as a race of wild huge men who dwelt in the far west, in the island of Thrinacia, but does not speak of their strife with the gods. Eurymedon, he says, slew them for their insolence to the immortals. According to Hesiod the Gigantes were the offspring of Ge, 'the earth,' and Tartarus, while later writers confound them with the Titans (q. v.), and make them, like the Titans, war with the Olympians. The legends of Hercules and Theseus represent these heroes as slayers of giants. The Gigantes are mostly placed in volcanic regions, as Cos and Sicily, and the legends relating to them seem connected with volcanic phenomena. Giants are much more important in Norse than in Greek mythology. This is in all likelihood due to the Northern nations being brought into close contact with gloomy and terrible natural phenomena comparatively unknown in the bright, warm climate of Greece. In the Northern mythology the giants (*Joetter*, *Jötuns*, and *Rimthurser*) were the incarnation of evil. They dwelt in a dark land of wild, snow-clad mountains, known as Jötunheim ('giant land'), on the shores of the great ocean, separated from the gods by the 'unfreezing river' Ising. They were the offspring of darkness and cold, were hideous and deformed, and had often several heads. The giantesses, however, were sometimes fair, *e.g.*, Gerde, whose beauty woke the love of Freyr, and are represented as stirring up discord among the gods. The Northern mythology represents the giant Ymir, who was produced from heat and ice, as the earliest of created beings. He was slain by the gods Odin, Vili, and Ve, who made the sea from his blood, and heaven and earth from his body. All the other frost-giants were slain save Bergelmir, who, escaping with his wife, became the father of the Jötuns, against whom the gods reared a wall made from the eyebrows of Ymir. Dwarfs are likewise important actors in Northern mythology and folk-lore. According to the younger Edda, the dwarfs were produced as maggots on the dead Ymir, and afterwards received human form and reason from the Aesir or gods. They were afraid of light, and lived in caves and in the bowels of the earth. They were very skilful in metallurgy, and especially in forging magic arms and armour. Thus the dwarfs Darin and Daalin forged the wonderful sword Tyrsing. The dwarfs occasionally aid men and are hostile to the giants. The north, south, east, and west are sometimes spoken of as dwarfs who uphold the four corners of heaven. It has been suggested that many of the tales of the Northern dwarf have arisen from the migration of a race of Lapps into Scandinavia. Both G. and D. appear constantly in medieval romance, whence they have passed into nursery tales. In the mythical English history of Brut and his descendants giants are mentioned as dwelling in Albion; and Cornish and Welsh giants are often met with in English folk-lore. See Geoffroy Saint Hilaire's *Histoire des Anomalies de l'Organisation*; Mallet's *Northern Antiquities*; Thorpe's *Northern Mythology*; Grundtvig's *Nordens Mythologie*; Grimm's *Deutsche Mythologie*.

Giant's Causeway, a singular promontory of most perfect columnar basalt in the N. of Ireland, running into the North Channel from the coast of Antrim, midway between the mouth of the Bann and Bally Castle. It consists of the lowest of three beds of highly crystalline basalt, and appears at Bengore Head, where the cliffs are from 400 to 500 feet high, forming a great mole or paved way 30 feet wide and 300 yards long, which dips towards the sea. The perpendicular columns are closely packed together, and are mainly hexagonal; but there are also columns with nine, eight, seven, five, and even three sides. There is great beauty in the transition of colour from the snow-white chalk which overlies to the almost black basalt, and in the lively tints of intervening beds of ochre and of green and red sandstones. Two similar promontories of minor size are known as the Middle and Little Causeways. The Irish name of the G. C. is *Clochan-na-bh Fomharaigh*, pron. *Cloghan-avowry*, *i.e.*, 'the stepping-stones or causeway of the Fomorians,' a race of pirates, who in semi-mythical times infested the Irish coasts, but were transformed by later legend into giants who wished to make a road to Scotland.

Giaour (the Turkish form of the Pers. *gebr*, which in turn is borrowed from the Arabic *kafir*, 'infidel'), the name given by the Turks to those who do not hold the Mohammedan faith. It is generally, but not necessarily, used as a term of reproach.

Giarr'e, a large town in the province of Catania, Sicily, near the sea, and 42 miles S.S.W. of Messina. The vicinity is famous for its wine, and about 5 miles above the town, on the side of Mount Etna, are several trees of remarkable size and age, and the remains of the famous *Castagno di Cento Cavalli*, held to have been formerly the largest chestnut-tree in the world. Pop. 17,197.—**G. Riposto**, about a mile distant to the E. of G., of which it is the port, is a station on the railway from Giardini to Catania. Pop. 6530.

Giave'no, a walled town in the province of Turin, N. Italy, on the Sangone, 17 miles W.S.W. of Turin. It has a castle of date 1369, and some manufactures of silks, linens, leather, and ironwares. Pop. 9683.

Gibbet. See HANGING.

Gibb'on (*Hylobates*), a genus of Catarhine or higher apes found in the E. Indies and E. Archipelago. They are distinguished by the great length of the anterior limbs, the hands reaching the ground when the animal is in the erect posture. The tail is abortive, but *callosities* or hard parts exist on the nates. The fur is thick and woolly. The common G. (*Hylobates lar*) is one of the best-known species. It is sometimes known as the white-handed G., and occurs in Malacca and Siam. The colour is black; the face bordered with a grey colour. The agile G. (*H. agilis*) and the silvery G. (*H. leuciscus*) are well-known forms, as is also the Siamang (*H. Siamang* or *syndactylus*) of Sumatra. The latter is an exceedingly man-like ape, and is the largest of the gibbons. The index and middle toes of the hind-feet (as indicated by the specific name *syndactylus*) are united by the skin as far as the nail-joint.

Gibbon, Edward, the greatest of English historians, was the son of a rich proprietor in Surrey and Hampshire, and was born at Putney, 27th April 1737. Being a weak child, he was allowed largely to educate himself, and from his early years read widely, especially in history. In his fifteenth year, at which age he proposed to write a history of the times of Sesostris, he was sent to Magdalen College, Oxford, where he remained only fourteen months, being converted to Roman Catholicism from reading two works by Bossuet, and consequently being forced to quit the university, to which he afterwards averred he owed no obligation. He was then placed at Lausanne under the care of a clergyman, who induced him to reaccept Protestantism. In 1758 he returned to Hampshire, entering no profession, but devoting himself to study. In 1761 he issued an essay in French *Sur l'Etude de la Littérature*, which was well received abroad. About this time he became a captain in the Hampshire Militia, and gained an experience of military movements which was, he says, useful to him when composing his history. He visited Paris and Lausanne in 1763, and while at Rome in 1764 formed the idea of writing his great work, as he sat 'musing amidst the ruins of the Capitol, while the barefooted friars were singing vespers in the Temple of Jupiter.' In 1770 his father's death made him master of a large fortune, whereupon he devoted himself to writing the history of the *Decline and Fall of the Roman Empire*. The first volume appeared in 1776, and the whole

edition was sold off in a few days. The book was completed at Lausanne in 1787 and published in 1788. G.'s attempt in his great work (chap. xv., xvi.) to explain the rise of Christianity by 'secondary causes' exposed him to much, and, on the whole, unmerited obloquy. He does not deny 'the ruling providence of the great Author' of Christianity, but thinks 'we may still be permitted, though with becoming submission, to ask, not indeed what were the first, but what were the secondary causes of the rapid growth of the Christian Church.' He returned to England in 1793, and died in his fifty-seventh year, January 16, 1794. G.'s was a cold, placid nature, almost untouched by passion or enthusiasm. Indifferent rather than cynical, he has been well called the perfect type of the conservative sceptic. When we turn, however, from the man to the author, it is impossible to refuse him an unbounded admiration. He is the loftiest example of historical genius in English literature. His theme was the grandest that ever fell to the lot of an historian, and no writer ever possessed learning more extensive and minutely accurate, or turned his studies to more splendid account. 'The work of G.,' says Mr. Freeman, 'as the grandest of historical designs carried out with wonderful power and accuracy, must ever keep its place; whatever else is read G. must be read too.' Carlyle has called G.'s work the splendid bridge between the old world and the new; and its special value lies in the parts which describe the transition from Roman to modern Europe, but nowhere is the scope of G.'s learning more manifest than in the picturesque episodes—such as the famous chapter on Mohammed—which enliven the march of the narrative. Unfortunately G. cannot always rise to the epical grandeur of his subject. He cannot, from the want of imaginative sympathy, breathe life into the great figures of the past nor reveal the natures of heroic characters. A skilful analyst of a dead civilisation, he cannot set forth the development of a living society. His style is at times obscured by allusive brevity, and is overburdened throughout by Latin derivatives; but it is nobly majestic, copious, and vivid, full of ornate picturesqueness, and rich in a kind of sombre, stately, and ironical epigram, expressed with a rhythmic elegance peculiar to its author. His *Autobiography* is deeply interesting as a frank revelation of character, and is marked by a delightful felicity of manner. The best editions of G. are those by Milman (12 vols. 1838-39), which contains a valuable Memoir, and Smith (5 vols. 1854–55). See also Minto's *English Prose Writers* (1872); and Stephen's *History of English Thought in the 18th c.* (Lond. 1876).

Gibbons Grin'ling, the greatest of all English woodcarvers, was of Dutch extraction, and was born at Rotterdam, 4th April 1648. He received an appointment in the Board of Works from Charles II., and was employed to do much of the ornamental carved work for the chapel of Windsor. The stalls of St Paul's choir are rich with foliage and festoon work from his hand, but the highest products of his genius are the beautifully executed fantasies of flower, fruit, and birds which adorn the panels, staircases, and pillars of the famous English mansions of the 17th c.—Chatsworth, Petworth, Burleigh, Southwick, &c. His delicacy and truth to nature evince high genius; his executive *finesse* is still unrivalled. He carved a point-lace cravat in wood for the Duke of Devonshire, and he could represent a feather in the same material with all the lightness of nature. G. died August 10, 1720.

Gibb'ons, Orlan'do, 'one of the rarest musicians of his time' (Anthony Wood), was born in Cambridge in 1583. At the age of twenty-one he was appointed organist of the Chapel-Royal, and in 1622 was made Doctor of Music by Oxford University. In 1625 he died of smallpox, caught on the occasion of King Charles's marriage, for which ceremony he had composed the music. He was buried in Canterbury Cathedral. Though he wrote other music besides, he owes his fame to his anthems, of which eighty have come down to us. They are simple, grand, and harmonious compositions. His brothers Edward and Ellis were also fine musicians, and his son Dr. Christopher G. was one of the best organists in the second half of the 17th c.

Gibbos'ity (Lat. *gibbus*, Gr. *kūbos*, *kuphos*, 'humpbacked'), the name given to a protuberance of part of the body, generally of the spinal column. This malformation depends on caries of the bodies of the vertebræ, with disintegration of the intervertebræ fibro-cartilage, and occurs most commonly in young children. It is almost always a strumous affection.

Gibb'ous (Lat. *gibbosus*, from *gibba*, 'a hump'), in astronomy, is the term used to describe the moon's figure when it is within a week of the full. Mars is the only planet which presents marked G. phases.

Gib'eah (Heb. 'a hill') was the name applied to several towns and places in Palestine—a city of Judah (Josh. xv. 57), and of Benjamin (xviii. 28); the place where the Ark remained for a time (1 Sam. vii. 1; 2 Sam. vi. 3); G. of Benjamin, the scene of the outrage on the Levite's concubine (Judges xix., xx.), mentioned during the wars of Saul (1 Sam. xiii., xiv.), in 2 Sam. xxiii. 29, and by Hosea (v. 8, &c.), which is most probably the same as G. of Saul (1 Sam. xi. 4), and as the modern *Tuleil-el-Ful.*

Gi'bel (*Cyprinus gibelio*), the name given to a species of the Carp (q. v.). It has, however, no *barbules* or mouth filaments, and has a hooked tail. The G. is found in many British ponds and rivers, but appears to be somewhat local in its distribution. It is more common on the Continent, and may attain a weight of 1½ or 2 lbs. Its common English designation is the 'Prussian carp.'

Gibelli'na, a small town of Sicily, in the province of Trapani, 34 miles S.E. of the town of Trapani. It stands among mountains, and near it is a hill named *Le Fenestrelle*, from being cut into a number of curious cells, supposed to have been troglodyte dwelling-places. Pop. about 5000.

Gib'eon (Heb. 'belonging to a hill') was the city—one of the four of the Hivites—whose inhabitants by a stratagem induced Joshua to make a league with them (Josh. ix. 3-15, 17), which was in the territory of Benjamin (most probably the modern *El-Jib*), and afterwards became a Levitical city (xxi. 17). G. was the scene of the encounter between the men of David and of Ishbosheth, under Joab and Abner (2 Sam. ii. 12-32), and there Amasa was afterwards slain by Joab (2 Sam. xx. 8-12). On the high-place at G. the tabernacle was placed for some time (1 Chron. xvi. 39, xxi. 29), where it was one of the first acts of Solomon, after coming to the throne, to visit it (1 Kings iii. 4). See Stanley's *Sin. and Pal.* (new ed. Lond. 1871).

Gibral'tar (a corruption of the Arab. *Gebel el Tarik*, *i.e.*, 'Tarik's hill'), one of the most southerly points of Spain, 60 miles S.W. of Cadiz, and an almost isolated promontory of towering rock, only connected with the mainland of Andalusia by the 'neutral ground,' a low sandy isthmus about half a mile broad and 1½ miles long. To the W. a deep crescent-shaped inlet between G. and Algeciras, known as G. or Algeciras Bay, has an extreme width of 5½ miles, a depth of 218 fathoms, is marked by five lights, and affords good anchorage. The 'Rock' extends N. and S. for some 3 miles, has an extreme breadth of three-quarters of a mile, and rises to a height of 1439 feet. It is a mass of grey primary marble, of a reddish colour towards the base, and presenting almost perpendicular cliffs to the N., E., and S., but sloping accessibly though abruptly on the W. side to the plateau or *pied à terre* on which the town is built, and which is protected by strong batteries and works of defence. Some points along the ridge, beginning at the N., are Rock-gun Fort (1337 feet), Middle Hill (1010), Signal Station (1255), Mount Misery (1300), O'Hara Tower (1408), and the highest peak, known as the Sugar Loaf. The headland to the S., Point Europa (in lat. 36° 2′ 30″ N., and long. 5° 15′ 12″ W.), supports the lighthouse of G. The rock is perforated by many large caves, the principal being the *Cueva de San Miguel*, which has an entrance 1000 feet above the sea, and which has been descended for 500 feet through a series of narrow passages and vast chambers hung with stalactites. The limited vegetation comprises asparagus, capers, palmitas, aloes, cacti, and various mosses; while among the animals are cattle, sheep, goats, rabbits, partridges, pigeons, woodcocks, and Barbary apes (the N. African *Simia ecaudatus*). Although G. has the warmest climate in Europe, it is now one of the healthiest places in the world. From July to November is the hottest season, and the 'G. fever' only appears once in about twelve years. The home supply of water is limited to one rich spring, but there are eight bomb-proof cisterns for rain-water capable of holding 40,000 tons. G., which may be regarded as the key to the Mediterranean, constantly maintains a garrison of some 5000 infantry and 1000 artillery. While to the N. it is honeycombed by strongly appointed galleries, towards the S. magazines, rock-hewn batteries, and steep escarps stretch out to Point Europa.

It is placed under a governor, who decides in civil cases, subject in those of importance to an appeal to the British Privy Council. In 1871 the revenue derived from customs, port and quarantine dues, land revenues, stamps, and licences, amounted to £38,156, the expenditure to £42,015. Next to Malta G. is the most expensive of the British possessions, the cost of maintenance being £306,433 in 1872-73. All religions are tolerated, and G. is the seat of a Protestant and of a Roman Catholic bishop. The *town* of G. consists of a lower and upper portion, with a difference of 100 feet of altitude. It is irregularly built, and the houses, many of which are in the English style, are generally painted in a dark colour. The chief buildings are those of the Government (formerly a Franciscan monastery), the Roman Catholic cathedral, the Protestant church, the hospital, three synagogues, a mosque, and, in the upper part of the town, part of a Moorish castle of the 8th c., now used as a military prison. In front of G. is the beautiful Almaden Garden decked with exotic plants. G. is a free port, and has an active transit trade with Spain, Portugal, Morocco, France, and Italy. It is a source of much Spanish smuggling. Pop. (1871) 18,695, of whom the majority are Roman Catholics, and 1800 Jews.

History.—The classical G., named *Calpe*, a corruption of the Phœnician *Alube*, formed part of Hispania Bætica, and was one of the Pillars of Hercules, Abyla (mod. *Ceuta*) on the African coast being the other. In 711, as the Arabs poured into Spain, a castle was erected on the rock by Tarik Ibn-Zeyad, a general of the Calif Al Walid, from which circumstance it was called *Gebel el Tarik*. G. remained a Moorish stronghold till 1309, when it was recovered by the Christians under Antonio de Guzman. Ferdinand IV. then strengthened the defence, and erected a dockyard at the Old Mole. In 1333 G. yielded to the Moorish King of Fez, and was only regained by treachery in 1462. During the Spanish war of succession a Dutch and English naval force, under the Prince of Hessen-Darmstadt and Sir George Rooke, bombarded G. and forced the governor to capitulate, 4th August 1704. It was vigorously but vainly besieged by the Spanish in 1704-5, was formally ceded to Great Britain in 1713, and again attacked by a force of 20,000 men under the Count de las Torres in 1727. When England was engaged in the struggle with her colonies and was at war with France, the Spanish made their grand and final attempt to overwhelm the garrison of G., and were met by one of the most obstinate and brilliant defences in history. It began on the 21st June 1779, and ended on the 6th February 1783, having lasted three years, seven months, and twelve days. The blockade began unexpectedly, but Admiral Rodney was able to force the lines, convey provisions, add 1000 men to the garrison (making it 6382), and remove civilians. The defence devolved on General Elliot (q. v.), the governor, and General Ross. Matters began to assume a serious aspect when the Spanish seized the African ports opposite in 1780; but in April of the following year G. was relieved for a time by Admiral Darby, who led 100 merchant vessels into the bay. All this time an active bombardment was going on by land and sea; for weeks together 6000 shells were daily thrown into the town. With a combined Spanish and French fleet of 47 sail of the line, 10 floating batteries, and 15 gun and mortar boats, 1000 pieces of heavy ordnance, and covered boats to land 40,000 men, a crowning onset under the Duc de Crillon was made on the 8th September 1782, and lasted till the 13th, when it was only repulsed by the use of red-hot balls and incendiary shells. The munitions used by the enemy in one night were estimated at £2,000,000. A peace was declared on the 2d February 1783; the thanks of Parliament were conveyed to the garrison, and General Elliot (q. v.) was made a Knight of the Bath and afterwards Lord Heathfield. An engagement took place here between the French and English fleets, 6th July 1801.

Gibraltar, Strait of (Sp. *El Estrecho de G.*, the *Fretum Herculeum* of the Romans), is the channel between the coasts of Morocco and Andalusia, and connecting the Mediterranean and the Atlantic. It is 36 miles long from E. to W., 900 fathoms deep, and has a breadth between Capes Trafalgar and Spartel of 25 miles, and between G. and Ceuta of 14 miles. There is a constant current eastwards.

Gib'son, John, an English sculptor, was the son of a landscape gardener, was born at Conway, N. Wales, in 1791, removed with his family to Liverpool in the beginning of the century, and there, at the age of sixteen (having previously manifested taste and power in drawing), was invited to enter the marble works of Messrs. Francis, under whom he soon became highly esteemed for his skill in designing, modelling, and carving. The friendship of Mr. Roscoe (the biographer of Lorenzo de Medici) enabled G. in 1817 to repair to Rome, where he was an apt and favoured student under Canova and Thorwaldsen successively. He made Rome his home, and though elected A.R.A. in 1833, and R.A. in 1836, he did not revisit England till 1845, and then only to return immediately to Italy. He died January 27, 1866. In his works the perfect form and spirit of the antique are revived. His first commissions were his group 'Mars and Cupid,' executed in marble for the Duke of Devonshire, and his 'Psyche borne by Zephyrs,' for Sir George Beaumont. Among other famous works are 'Sleeping Shepherd Boy,' 'Aurora,' and the 'Wounded Amazon.' His 'Helens,' 'Sapphos,' 'Proserpines,' &c., are numerous; and while these are classic in form and ideal, they are also informed with a character and personality directly the outcome of G.'s own genius. But the constant effort to bring sculptural art back to the conventions of Greek design led to the waste of his skill in the creation of beautiful anachronisms. His 'tinted' Venus, Hebe, &c., slightly coloured and gilt, were defended by himself as having precedents in Greek art; but the experiment has had no effect upon recent sculpture. G. also executed a number of noteworthy portraits, statues, and busts. He left a representative collection of his works to the Royal Academy, where the 'G. Gallery' was opened in November 1876. See Eastlake's *Life* (1870).

Gibson, Thomas Milner, an English politician, born at Trinidad in 1807, was the son of Major T. M. G. After an education at the Charterhouse and at Trinity College, Cambridge, where he became a wrangler, he entered Parliament (1837) as Conservative member for Ipswich. He soon, however, became a 'philosophical Radical and free-trader,' and lost his seat in 1839, but was returned as one of the representatives of Manchester in 1841. After this G. became a prominent member of the Anti-Corn-Law League, and an eloquent exponent of the principles of the Manchester school. In 1857 he and Mr. John Bright were ousted from Manchester on account of the views they held on the subject of the Crimean war, but the same year he found a seat for Ashton-under-Lyne. The most successful thing as a parliamentary tactician he ever did was to overthrow the Palmerston Administration (February 19, 1858) by a majority of 234 to 215 through an amendment to the celebrated Conspiracy to Murder Bill. In the next Government of Lord Palmerston, G., who had once under Earl (then Lord John) Russell been Vice-President of the Board of Trade, became its President, and held the office till the Russell-Gladstone Ministry broke down on the question of Reform in 1866. G. is best known for his efforts in repealing the newspaper stamp, the advertisement duty, and the tax on paper—known as 'taxes on knowledge.' He retired from public life and Parliament at the general election of 1868.

Gidd'iness. See VERTIGO.

Gid'eon (Heb. 'hewer' or 'destroyer') was the fifth of the Judges of Israel. Roving bands of Midianites had for seven years periodically carried off the crops and cattle of the Israelites, when 'an angel of Jehovah' appeared to G. and commissioned him to deliver the people from this oppression, which the narrative implies was inflicted as a punishment for indulging in the worship of Baal (Judges vi. 1, 25). G. accordingly inaugurated his mission by casting down the altar of Baal in Ophrah. The Midianites having encamped in great force in the Valley of Jezreel, he called together the men of the neighbouring tribes. With a band of 300 chosen from these, he gained an easy victory over the enemy, having first produced a panic in their camp by a stratagem (Judges vi., vii.). Pursuing the fugitives over the upper fords of the Jordan, he defeated them a second time, and took their two kings Zeba and Zalmunna, whom he afterwards slew. Meantime the Ephraimites had seized the lower fords, and took and slew, doubtless with many others, two chiefs, Oreb and Zeeb. G. declined the honour which was now offered to him of becoming king, but lapsed into idolatry so far as to set up an Ephod (q. v.) (Judges viii.). Having thus shattered the power of the Midianites, he secured for his country safety from such depredations till his death, forty years afterwards.

Gien, a French town in the department of Loiret, on the right bank of the Loire, 38 miles E.S.E. of Orleans. It has a castle dating from the 15th c., and several very old buildings; the chief industries are printing and the making of crockery and whiting; and there is trade in corn, bay salt, saffron, wool, serges, coal, &c. G., the *Genabum* of Cæsar, was at one time a separate county. Pop. (1872) 7068.

Gies'eler, Johann Karl Ludwig, an ecclesiastical historian, was born at Petershagen, near Minden, 3d March 1792. He was educated at the University of Halle, and had entered upon a career as a teacher, but it was interrupted by his becoming a volunteer in the patriotic war against France. In 1815 he resumed his profession, and became in succession *con-rector* of the gymnasium at Minden, director of the gymnasium at Kleve, ordinary professor of theology at Bonn, and professor at Göttingen. His death took place July 8, 1854. G. was a philanthropist, a writer in magazines and of books on various subjects. See his *Narratio de Bogomilis* of Euthymius Zygabenus (Gött. 1842), and Siculus' *Historia Manicheorum seu Paulicianorum* (Gött. 1846); but he has attained his chief eminence by his *Lehrbuch der Kirchengeschichte*, of which three vols. were published in his life, two posthumous ones appearing under the editorship of his pupil, E. R. Redepenning, who has also given a notice of his life. It is particularly valuable for its apt and instructive quotations. There is a good English translation by Professor Henry B. Smith (4 vols. New York, 1856–59).

Giess'en, the capital of the province of Upper Hessen, in the grand-duchy of Hessen-Darmstadt, at the confluence of the Wieseck and Lahn, 35 miles N. of Frankfurt by railway. It has a Protestant university (*Ludoviciana*), founded by Prince Ludwig V. in 1607, which has extensive scientific collections, a celebrated laboratory, a botanical garden, and a staff (1875) of 55 professors and 340 students. In the time of Liebig there were 700 students. G. has several quaint old public buildings, and its streets are crooked and narrow. The chief industries are in tobacco and liqueurs; and in the vicinity are iron and manganese mines. Pop. (1872) 12,225. G. arose in the 12th c., and was fortified in 1530. See Nebel's *Geschichte der Universität G.* (Marb. 1828), and Duller's *G. und Umgebungen* (2d ed. Gies. 1851).

Giff'ord, William, critic and satirist, was born at Ashburton, Devonshire, April 1756, and served in a coaster and as a shoemaker's apprentice, until several poems which he wrote won the notice of William Cookesley, a surgeon, who enabled him to study at Exeter College, Oxford. In 1794 he produced the *Baviad*, and in 1795 the *Mæviad*, two crushing satires against the Della-Cruscans (q. v.). He was made editor of the *Anti-Jacobin* in 1797, issued a translation of Juvenal in 1802, an edition of Massinger in 1805 and of Ben Jonson in 1816, and edited the *Quarterly Review* from 1808 to 1824. G. died in London, December 31, 1826. His editions of Ford and Shirley appeared after his death. G.'s editions of the old English dramatists have still some value, but his criticisms are now well-nigh forgotten, and his satires are as dead as the verses which they annihilated. He had a vigorous, but coarse and narrow mind; his criticism was wholly swayed by political prejudice; and his strictures were for the most part bluntly abusive, with occasional touches of malignant pungency and sour wit. See G.'s Autobiography prefixed to his *Juvenal*.

Gift means in English law a gratuitous transfer of property, real or personal. In the former case the transfer can only be made by deed. In the latter it may be made by deed or by delivery of the property with words of G. A gratuitous promise to give is not binding in law. A G. by a person insolvent at the date of it, though effectual against himself, is void against his creditors; and if any one give heritage to another and then sell the same, the gratuitous deed is void against a *bona fide* purchaser. No personal property can pass by G. of which absolute possession is not given by the donor; thus delivery of a stock receipt will not give the stock—there must be a transfer; but delivery of a bank-note transfers the property. In Scotch law G. is usually called a Donation (q. v.). In Scotland, as in England, a G. by an insolvent person is ineffectual against his creditor.

Gigue. See JIG.

Gijon', a Spanish town in the province of Oviedo, on the Bay of Biscay, 20 miles N.N.E. of the town of Oviedo. It is well built, is partly encircled by old walls, has an ancient castle, batteries, and an educational institution, *Instituto Asturiano*, with several professorships. The harbour is dangerous of access, but is safe and commodious within. There are large cigar manufactures and trade in coal and fruit. G. is the chief seaport and trading town in Asturias. Pop. 10,378.

Gi'la, a river of the United States, rises in the state of New Mexico, flows W. through Arizona, and joins the Colorado 70 miles from its mouth in the Gulf of California, after a course of 450 miles, 180 of which are navigable for flat boats. It is partly hemmed in by precipitous cliffs nearly 1000 feet high, and along its banks are found traces of a vanished civilisation.

Gil'bert, Sir Humphrey, a famous Devonshire gentleman of the Elizabethan era, born at Dartmouth in 1539, educated at Eton and Oxford, adopted the profession of arms, and rendered distinguished service in the Irish wars (for which the Queen conferred upon him the honour of knighthood) and in the Low Countries. He sat in the Parliament of 1571. In 1576 he wrote a treatise on the N.W. Passage to India, and two years after succeeded in obtaining from Elizabeth a patent authorising him to 'discover and take possession of any remote heathen and barbarous lands not being actually possessed by any Christian prince or people.' Aided by his half-brother, Sir Walter Raleigh (G.'s mother was twice married, the second time to Walter Raleigh of Fardel, Devonshire), he fitted out a naval squadron for discovery and conquest in 1579; but his ships, damaged by tempest and beaten in an engagement with the Spaniards, were driven back to England. In 1583 he organised another expedition of five vessels and 260 men, which was still more disastrous. With four out of his five vessels G. reached Newfoundland, and in terms of his patent took possession of it in the Queen's name. Sailing southward G. lost the largest of his three remaining ships, with nearly all on board, off Cape Breton. On the 9th September in the midst of a storm, G., 'sitting abaft with a book in his hand,' more than once exclaimed 'We are as near to heaven by sea as by land.' On the evening of the same day the frigate in which he sailed went down with all on board. Besides being a conspicuously brilliant, chivalrous figure in an age renowned for brilliance and chivalry, G. is to be remembered as taking a prominent part in laying the foundations of English colonisation in America.

Gilbert, William, an English physician and natural philosopher, was born at Colchester in 1540. He graduated at St. John's College, Cambridge, as M.A. in 1564, and M.D. in 1569, after which he travelled abroad for a time. On his return he settled in London in 1573, entered the Royal College of Physicians, and ultimately became physician to Queen Elizabeth. His pension enabled him to carry on the researches in magnetism for which his name is famous. In his work *De Magnete Magneticisque Corporibus, et de Magno Magnete, Tellure, Physiologia Nova* (1600), he establishes the polar property of the magnet, shows the earth to be magnetic, and calls those poles by the same name which repel each other, so that it is the S. pole of a magnetic needle which points to the N. He further gives a list of substances which, like amber, become electrified by friction, and lays down the fundamental laws of electricity. He was continued in his position as royal physician by King James, but died at Colchester, November 30, 1603, soon after. His other work, *De Mundo nostro Sublunari Philosophia Nova* (Amst. 1651), was printed from a MS. in the library of Sir William Boston.

Gilbert Islands, or **Kingsmill Group**, the name given to sixteen inhabited coral islands of Mulgrave Archipelago, in the Pacific, lat. 1° S.–2° 30′ N., long. 172°–174° 30′ E. They are low-lying, and are covered with a thin layer of rich soil, in which grow coco-nut, taro, and pandanus trees. The two largest, Drummond's Isle and Knox's Isle, are 30 and 20 miles long respectively. The inhabitants, 60,000 in number, are like the Malays in feature, and have been known to practise cannibalism. Missions are maintained here by the Hawaiian and American Congregationalists.

Gilbo'a (Heb. 'bubbling fountain'), a mountain range in the E. of the plain of Esdraelon, which is only mentioned in the Bible in connection with the defeat and death of Saul and Jonathan by the Philistines (1 Sam. xxxi. 1; 2 Sam. i. 6, &c.).

Gil'das, a writer who probably flourished in the 6th c., but whose life has come down to us only in two legends, neither of which is credible. According to one of his editors, Mr. Stevenson, 'we are unable to speak with certainty as to his parentage, his country, or even his name, the period when he lived, or the works of which he was the author.' Mr. Skene, a better authority, in his *Four Ancient Books of Wales* (vol. i. pp. 33–37), expresses himself more moderately. He says—'The treatise [of G.] is evidently the work of one man, and there is evidence in the work itself of his date. The writer states that he was born in the year in which the battle of Badon was fought, and that he wrote forty-four years after. According to the oldest Welsh annals, the battle of Badon was fought in the year 516, which would place the composition of the treatise in the year 560, and the Irish annals record the death of G. in 570, ten years later.' The work of G. is in Latin, and is sometimes called the *De Excidio Britanniæ*. It consists (1) of a 'Preface,' in which he explains why he undertook his task; (2) a brief 'History of Britain during the confusions before and after the withdrawal of the Romans;' (3) an 'Epistle,' containing chiefly denunciations of the British 'kings' for their wickedness, out of which with difficulty some fragments of fact can be extracted, and ending with a long string of warnings from the Old Testament. Three MSS. of G. once existed; there are now only two, both in the public library at Cambridge, the one belonging to the 13th, the other to the close of the 14th c. The best editions are those of Stevenson, published by the 'English Historical Society' in 1838, and Petrie in the *Monumenta Historica Britannica* (Lond. 1848). There is an English translation by Habington (1638), which has been reproduced with certain 'modernisations' by Dr. Giles in Bohn's *Antiquarian Library*. See Skene's *Four Ancient Books of Wales* (2 vols. Edinb. 1868).

Gil'ding, the art of applying a superficial coating of gold to wood, metal, and other bodies. This is accomplished by several distinct methods.

With wood two kinds of G. are practised, called burnish G. and oil G. *Burnish* G. as applied to picture-frames consists principally of the following processes:—(1) Priming with *thin white*, a composition of whiting and pure size, and closing pores and irregularities with fine putty made without oil. (2) Coating four or five times with a whiting and size mixture, termed *thick white*, each coat being allowed to dry, the moulding being kept open and sharp by means of suitable tools, and the edges and surface smoothed with pumice and glass-paper. (3) Gold-sizing, or preparing the ground on which the gold leaf is to be laid. The burnish gold size is a soft mixture of pipeclay, Armenian bole, black lead, suet, and bullock's blood. A portion of it is melted in hot clear size, and from four to eight coats of the warm creamy mixture are laid on the moulding. Care is taken to make each coat equally thick, and to give it time to dry before another is applied. The whole is then smoothed, especially the parts to be produced in *matt* or dull gold, and the parts to be burnished are recoated with gold size. (4) G., in which the workman cuts the gold-leaf into narrow strips corresponding to the width of the depressions or prominences of the moulding. He then moistens with water a few inches of the surface, lays down a strip of gold with the aid of a *tip* brush, and presses out the superfluous water with a dry brush. The whole moulding is thus covered, and dried, and then burnished with agate. (5) Deadening the unburnished parts with weak size. (6) Faulting or covering little holes, previously wetted, with leaf, and strengthening the dull parts with another coat of size.

Oil G. differs slightly from the foregoing. A thin coat of white lead in oil is first applied, then red or yellow oil paint, next oil gold size, a mixture of boiled linseed oil and ochre. When the gold size is partially dry and sticky the gold leaf is laid on. Varnish may afterwards be brushed over it. Oil G. cannot be burnished, and alone can be washed.

Leather is gilded by applying *glaire* or egg albumen, and pressing down the gold leaf upon it with heated implements. Agate is used for burnishing.

Metal G. is accomplished by chemical means. *Wash G.*, formerly much practised, is still employed to some extent on account of its durability. Amalgam of gold of a pasty consistence is applied to the surface of the article to be gilded, and the mercury is dissipated by heat, leaving a thin film of gold, which is burnished with bloodstone.

G. by Immersion.—Copper articles may be coated by immersing them in a boiling-hot solution of perchloride of gold and bicarbonate of potash.

Electro G.—In this process, for details of which see ELECTRO-METALLURGY, the metal article is dipped into a bath containing a hot solution of auro-cyanide of potassium. Wood or any substance that can be coated with blacklead may be electro-gilded.

Porcelain or *glass* is gilded by painting it with powdered gold mixed with oxide of bismuth, borax, and gum-water. Heat in a muffle fixes the gold, which has to be burnished to enhance its lustre.

Gil'ead (Heb. 'a hard rocky region'), a mountainous region E. of the Jordan, first mentioned in connection with Jacob's flight from Laban (Gen. xxxi. 21), was taken possession of by the tribes of Reuben and Gad and half-tribe of Manasseh on the arrival of the Israelites at Canaan (Num. xxxii. 1, 29; Josh. xii. 1–6). Under the Romans G. prospered greatly, and several splendid towns were built. Under Turkish rule its population consists of a few wandering tribes.

Gilfill'an, Rev. George, was born at Comrie, Perthshire, in 1813. He was educated at Glasgow University, and in 1836 became minister of the School Wynd U.P. Church, Dundee, a charge which he held till his death, August 13, 1878. He achieved considerable popularity as an author and lecturer. Among his works are *A Gallery of Literary Portraits* (1845); *The Bards of the Bible* (1850); *The Martyrs, Heroes, and Bards of the Scottish Covenant* (1852); *History of a Man* (1856); *Christianity and our Era* (1857); *Alpha and Omega* (1860); *Night*, a poem (1867); *Modern Christian Heroes* (1869); *Life of Sir Walter Scott* (1870). His writings are overcharged with metaphors, vehement and rhapsodical, but display some insight into the nature of poetry, and are not without flashes of genius and felicities of erratic criticism.

Gill (Old Fr. *gaille* or *jale*, from Low Lat. *gillo* or *gello*, 'a flask') is a measure of capacity, the fourth part of a pint, and $\frac{1}{32}$ of a gallon.

Gill (Lat. *gula*, 'the throat'), or **Bran'chia**, the name given to the typical form of breathing organ in aquatic animals. In the typical fishes, for example, the gills consist of a number of filaments borne on the *branchial* or gill arches, each filament being composed of a network of minute blood-vessels, in which the air is exposed to the action of the oxygen of the surrounding water. In other fishes (as in the lampreys, sharks, rays, &c.) the gills exist as closed pouches or sacs, the lining-membrane of which consists of a network of capillary vessels. In fishes the gills are usually covered by an *operculum* or G.-cover, and water taken in by the mouth for the purpose of breathing is ejected, after passing over the G., behind the *operculum*. In some forms, such as proteus and axolotl amongst the *Amphibia* (q. v.), external gills exist, and in the tadpole stage of the frogs and toads both external and internal gills are temporarily developed. Among lower or invertebrate types gills of various kinds are found. Thus among Molluscs they form the breathing organs of cuttlefishes, Lamellibranchiates (q. v.) (mussels, oysters, &c.), of many Gasteropods (q. v.) (whelks, &c.), and of *Pteropoda* (q. v.). Lobsters, crabs, and other crustaceans breathe by gills, which exist as vascular processes adapted for bringing venous blood in contact with the oxygen of the surrounding water.

Gilles, St., an old French town in the department of Gard, 12 miles S.S.E. of Nîmes. It has a beautiful Romanesque church of the 11th c., and is noted for its fine wines. Pop. (1872) 6211.

Gilles'pie, George, a notable Scotch divine, born at Kirkcaldy in 1612. He was ordained minister of Wemyss in 1638, translated to Edinburgh in 1642, and in the following year was appointed commissioner from the Church of Scotland to the famous Westminster Assembly. The ability which he showed in theological discussion excited the admiration even of his Erastian opponents. In 1648 G. was elected moderator, but died prematurely in the same year. His *Dispute against the English Popish Ceremonies*, *Aaron's Rod Blossoming*, and *Miscellany Questions*, are meritorious works, but his historic eminence is greater than his literary fame.

Gill'ies, John, LL.D., a Scottish historian and classical scholar, was born at Brechin, Forfarshire, January 18, 1747.

Educated at Glasgow, he tried his fortune in London as a man of letters, was for some time travelling tutor to the sons of the second Earl of Hopetoun, and in 1793 succeeded Robertson as historiographer-royal for Scotland. He produced a number of histories and translations—*History of Ancient Greece* (1786), translations of the *Orations of Isocrates and those of Lysias* (1778), *Aristotle's Ethics and Politics* (1804), *Aristotle's Rhetoric* (1823), and *View of the Reign of Frederick II. of Prussia* (1789)—all of which are nearly quite forgotten. G. died February 5, 1836, at Clapham, London.

Gill'ray, James, an English caricaturist of Scotch parentage, was born at Chelsea in 1757. He was apprenticed to a letter-engraver, but it was not until, throwing aside his graver, he spent some time with a troop of strolling players, that he seems to have discovered that caricature was his true vocation. After studying at the Royal Academy, he allied himself with a publisher named Humphreys, with whom he continued to live till his death, and who printed and sold his drawings, which amounted in all to over 1200 in number. His caricatures, political and social, are often marred by the coarseness that characterised his time, but are always humorous and patriotic, and often savage in their moral intensity. He died June 1, 1815. G. has been restored to his rightful place in the history of intellectual life in England by the splendid edition of his *Works, with a History of his Life and Times*, by Thomas Wright, F.R.S. (Lond. 1873).

Gill'yflower (frequently written *gilloflower*, and corrupted into *July-flower*, from the French *giroflée*). G. is generally applied to varieties of the garden stock, the origin of which is *Matthiola incana*, a Cruciferous plant indigenous to Britain, and *M. annua*. Clove G. is applied to *Dianthus caryophyllus*, the clove-pink of gardens, and marsh G., sometimes to *Lychnis floscuculi* or Ragged Robin.

Gilo'lo (*Halmahera*), the chief island of a group of the same name in the Moluccas, in long. 128° E., and on the equator. It is separated from Celebes by the Molucca Passage, from New Guinea by G. Channel, and from Ceram by Pitt's Passage. Area, 6500 sq. miles. It is of volcanic origin, is mountainous and luxuriantly wooded, and exports spices, fruits, sago, cattle, horses, gold-dust, pearls, edible bird's-nests, &c. G. belongs in part to the Dutch. Its chief town is of the same name.

Gil Polo, Gaspar, a poet of Spain, born at Valencia about the beginning of the 16th c., held various honorary posts under Philip II. of Spain, and died at Barcelona in 1591. He is chiefly notable as a lyric poet, and as continuator of Montemayor's *Diana*, under the title *Primera Parte de Diana enamorada, Cinco Libros, que prosigue los Siete de Jorge Montemayor* (1564; Cerda's ed. with G.'s *Canto de Turia*, 1802). His works were much admired when they appeared, and still give the impression of strength and lucidity.

Gilt'head, a name applied to at least two distinct species of Teleostean fishes. One of these (*Chrysophrys aurata*), found in the Mediterranean, belongs to the family of the *Sparidæ*, which includes the sea-bream, and in its turn forms a division of the *Acanthopterygii*. The Mullets (q. v) are nearly allied to the *Sparidæ*. The *C. aurata* possesses a crescentic golden spot over the eye, and a violet patch over the gill-cover. The back is blue, and the sides marked with golden bands. The fins are bluish, and the bases of the dorsal and anal fins are bordered by very prominent scales. The teeth are large and powerful, and are used for bruising and crushing the shell-fish on which the fish feeds. The G. was a favourite in the *aquaria* of classic times. The name is also applied to the *Pagellus centrodontus*, or common sea-bream, from the silvery hues of its head. The eye is very large and yellow; the body colour, a grey tinted with red; while a dark patch occurs at the base of the pectoral fins, which with the tail-fin are coloured red. This fish is very common on the S. coasts of Britain.

Gilt Toys, a technical name for cheap jewellery, comprising lockets, brooches, and all kinds of personal ornaments, largely manufactured at Birmingham. By the aid of the stamp and screw-press the requisite form is given to the metal, which is then electro-plated with a very thin film of gold. Sometimes imitation gems, shell cameos, jet, and other materials are used in combination with the gilt metal. In this way the finest jewellery is imitated, and may be obtained at an astonishingly low price.

Gil Vicen'te, 'the Plautus of Portugal,' was born about 1470, his birthplace being still a matter of dispute. After studying law at Lisbon University, he devoted himself to producing dramas for the courts of Emmanuele and of Joao III., the latter king even taking a part in one of his comedies. He seems to have been an actor as well as an author, but little is known of his life. He died at Evora in 1557. G. is the founder of the Portuguese, and, in some degree, of the Spanish drama. His works consist of *autos*, or religious pieces, comedies, tragi-comedies, and farces. The mythological machinery of G.'s plays is often grotesquely absurd, and their plots are loose and careless, but they show rich invention and humour, and, especially in the farces, which are really comedies, much insight into character and lively natural dialogue. The verse is flowing and harmonious. G.'s complete works were edited by Feio and Monteiro (Hamb. 1832). See Bouterwek's *Geschichte der neueren Poesie und Beredtsamkeit* (1801–19).

Gim'bals (Lat. *gemelli*, 'twins') are two concentric metallic rings, the inner of which is movable about a diameter of the outer as axis, while the outer is movable round a horizontal axis perpendicular to the former. By such an arrangement, an object attached to the inner ring will preserve its originally horizontal position for *any* motion. The principle is applied in the mounting of ships' compasses, portable barometers, &c.

Gim'blet (Fr. *gibelet*, probably connected with *wimble*, 'to twist'), a tool for boring holes in wood. Its conical point combines the principles of the wedge and screw, and is followed by a groove for clearing, which may be either straight or spiral.

Gimigna'no, San, an old Italian town in the province of Siena, 22 miles S.S.W. of Florence. It has a mediæval appearance, and its tall towers, whence it was called *San G. delle belle torri*, are still standing. Of its churches the most interesting are *La Collegiata*, built in the 11th c., and *S. Agostino*, begun in 1280. G. was a thriving place in the 13th c. Pop. 7425.

Gimp, or **Gymp**, a kind of silk, cotton, or woollen braid, with a wire or coarse thread twisted through it, used as edging by upholsterers.

Gin (contr. from 'engine;' Lat. *ingenium*, 'a contrivance' or 'invention') is a word that was at one time often used by engineers and millwrights for certain descriptions of windlass employed to raise weights, drive piles, &c., either by hand or by animal power. It now generally denotes a machine for cleaning and preparing cotton or wool.

Gin, a spirit for drinking, prepared either from malt or from raw grain, and flavoured properly with juniper berries, whence the name, which is an abbreviation of Geneva, itself a corruption of the French *genièvre*, 'juniper.' The manufacture of G. is peculiarly a Dutch industry, centring at Schiedam, whence the spirit is very frequently known as Hollands or Schiedam. From that country it is largely exported to most quarters of the globe, but Great Britain and the United States of America are the principal customers. Hollands G. is usually imported in peculiar quadrangular bottles. The spirit when pure and genuine has a powerful diuretic influence, owing to the essential oil of juniper it contains, which renders it medicinally of considerable value, but more than any other intoxicating beverage it is subject to adulterations of a most pernicious character. It is the favourite drink of the lower orders in London, and to meet their tastes for a potent and pungent stimulant, a harsh, ill-rectified spirit is compounded with oil of turpentine, common salt, and many deleterious essential oils, which communicate a factitious strength to the spirit. The imports of Hollands G. into Great Britain during 1874 amounted to 324,260 proof gallons, valued at £59,535.

Gin'gal, or **Gingall**, a Chinese piece of ordnance of great antiquity, and still employed as a wall-gun. It is said that breech-loading gingals which have been in use for centuries may be seen in Northern China.

Gin'ger (formerly *gingiber*, Fr. *gingembre*, Lat. *zinziberum*, from Sansk. *çringa-vera*, 'horn-shaped'), the name applied to the root-stock or rhizome of *Zingiber officinale*, a plant belonging to the Monocotyledonous order *Zingiberaceæ*, and a native of

the E. Indies, where it is also extensively cultivated, as well as in the W. Indies, Africa, and China. G. is either preserved green in syrup or dried. There are several white and black varieties. Upwards of 550 tons are annually imported into Britain. It is an aromatic stimulant, and is largely used as a condiment for flavouring.

Ginger-Beer', a pleasant, refreshing, non-alcoholic beverage, frequently prepared on a small scale for domestic use. The following recipe produces an excellent quality:—To each gallon of water used add one pound of refined sugar and about one-third of an ounce of ground ginger. Boil this for an hour, then add the white of two eggs, and remove the scum. Strain the liquor into a vessel to cool, then cask it up with the juice and peel, fine cut, of a lemon. To this add a very small quantity of brewer's yeast, and bung tightly up for a fortnight, then bottle, and a fortnight thereafter the G.-B. will be fit for use.

Gin'gerbread, an ancient and (especially with children) a favourite sweet cake. There are two kinds, one baked thick and soft; the other, thin and crimp when baked. Of the numerous ways of making soft G., the following is an example:—Half a pound of butter, a quart of treacle, eight eggs, four table-spoonfuls of ginger, two tea-spoonfuls of carbonate of ammonia, kneaded thoroughly up with flour into a very stiff dough. Lemon peel and almonds are frequently added, and the whole baked in an oven. Hard G. requires no 'raising,' and it is rolled out thin and baked in flat pans in a moderately hot oven.

Ginger-Wine', or **British Wine**, is a popular and cheap liqueur manufactured on a considerable scale in Great Britain. To every fourteen gallons of water are added six pounds of fine pounded sugar, four ounces of ground ginger, and the white of two eggs. The mixture after boiling a quarter of an hour is skimmed and decanted into an earthenware vessel to cool, when the juice and peel of four lemons and half a pint of brewer's yeast are added. After fermenting for a day the liquor is racked off into a cask, and kept closely bunged up for two weeks. Before bottling, a little alcohol is generally added to improve its keeping qualities.

Gingh'am (Fr. *guingan*), a cotton fabric originally manufactured in India, and thence introduced into Europe. It differs from calico in this respect—that the colours are produced by dyeing the yarn, and not by printing the cloth. Britain has now largely taken the Eastern trade out of the hands of the native manufacturers. The chief kinds of G. are Earlston ginghams, power-loom seersuckers and checks, muslin grounds, coloured diapers, derries, Hungarians, umbrella ginghams. Glasgow is a great seat of the G. trade.

Gink'go, or **Gin'go**, the Japanese name for *Salisburia adiantifolia*, or maidenhair tree, a large tree belonging to the natural order *Taxaceæ*. It is grown in China and Japan, and also in Britain as an ornamental object. Its fruit is astringent and resinous, and an oil is extracted from the seed. Its wood is yellowish white and takes on a fine polish.

Gin'seng, the name given to the roots of the species of *Panax*, a genus belonging to the natural order *Araliaceæ*. G. is greatly esteemed by the Chinese, who believe that it can remove fatigue and completely restore exhausted animal power. The word G. is said to mean the 'wonder of the world.' The root is aromatic and mucilaginous.

Giober'ti, Vincen'zo, an Italian philosopher and political writer, was born at Turin, 5th April 1801. He was educated for the Church, in 1825 was made Professor of Theology in his native city, and in 1833 court chaplain. Suspected of sympathy with Young Italy, and accused of complicity in a republican plot, G. was sent into exile; and till 1847 he lived abroad, chiefly in Brussels, busied with literature. The works published during this period are mostly on philosophical subjects, and comprise an *Introduzione allo Studio della Filosofia* (1839) and a treatise *Dello Bello*. But the political ideal advocated in *Il Primato civile e morale degli Italiani* (1843) immediately left an abiding mark on the history of Italian political thought; and when G. returned to Italy in 1847, he was received with popular enthusiasm, immediately obtained political appointment, and soon stood at the head of a short-lived democratic Ministry. The new premier sent G. to Paris in 1849, where he died, 26th October 1852, ever faithful to the central thought of the *Primato*, that the new birth of Italy was to be found in a confederation of the Italian states under the primacy of the Pope, with the Piedmontese King as military protector. G. was buried with public honours at Turin. G. was a zealous but enlightened Catholic. His *Il Gesuita moderno* appeared in 1847, *Il Rinuovamento civile dell' Italia* in 1851. G.'s philosophy has of late attracted notice. A collected edition of his works was published in 9 vols. (1843-45), and his posthumous writings appeared in 1859. See Spaventa, *La Filosofia di G.* (2 vols. Nap. 1864).

Gio'ja, Melchiore, an Italian political economist, was born at Piacenza, 20th September 1767. He was educated at the College Alberoni, and first attracted notice by a prize essay in favour of the Republican form of government. In 1797 he was appointed state historiographer at Milan, and in 1809 was employed to draw up a statistical report of Italy. He was a keen satirist (as his *Il Povero Diabolo* shows), and a sharp critic, especially of those who criticised him; but at the same time he did very substantial work as a statistician. G. died at Milan, January 2, 1828. His best works are *Dell' ingiuria, dei danni, del soddisfaci mento e relative basi di stima* (Milan, 1802); *Nuovo prospetto delle scienze economiche ossia somma totale delle idea teoriche e pratiche in ogni ramo d'amministrazione privata e pubblica* (1815-19); and *Filosofia della Statistica* (1826).
